1.1 Nature and Scope of Biology

Science: The term science is derived from Latin word scientia which means knowledge. So, the term 'science' is used for knowledge gained by actual observation, found correct on verification and put in a systematic manner or science provides us information based on facts. There are several branches of science, each dealing with a specific subject.

Biology: It is the combination of two Greek words bios and logos. Bios means life and logos means study. Thus, biology is the branch of science which deals with the study of life. The first major biological observations were made by ancient Greek naturalist Aristotle (384-322 B.C.). Aristotle has been designated as Father of biology. The term biology was given by French naturalist Lamarck and Gottfried Treviramus of Germany (1744-1829). Biology has been further classified into.

(1) Botany (2) Zoology.

The science of plants is called Botany. The word botany has been derived from Greek word botane which means pasture or plants. Technically, botany is called Phytology (Gk. phyto = plants; logos = study). Theophrastus (370-287 B.C.) is known as Father of botany. Zoology is the study of animals (Gk. zoon = animals; logos = study). Aristotle is called Father of zoology. Being broad-based and with multi-disciplinary approach, the term biology has been replaced by Life Sciences or Biological Sciences.

Microbiology: It is the branch of biology which deals with different aspects of microorganisms. **Leeuwenhoek** (1632-1723) is called Father of microbiology.

Some Branches of Biology

Anatomy: Study of internal structures of plants and animals after dissection.

Biochemistry: Study of chemistry of living matter (i.e., chemical composition, nature, mode of formation, functioning) in relation to life activities.

Cytology: Study of the structure and functions of cells and their organelles.

Ecology: Study of relationship between organisms and environment.

Embryology: Study of developmental stages of organisms upto hatching or birth.

Endocrinology: Study of endocrine glands and hormones action in animals.

Evolution : Study of the origin of life and the gradual differentiation or descent of species.

Histology: Study of tissues by microscopy.

Immunology: Study of resistance of organisms to infection.

Limnobiology: Study of fresh water lakes, ponds and streams.

Morphology: Study of form and structure of animals.

Palaeozoology: Study of fossil animals.

Physiology: Study of functions of various parts within the organisms.

Radiobiology: Study of effects of radioactivity on life.

Taxonomy: Study of classification of organisms and their evolutionary relationships with other organisms.

Zoogeography: Study of the distribution of animals over the earth.

Zoopathology: Study of diseases of animals.

Specified Branches of Biology

Acarology: Study of mites and ticks.

Agriculture: Science of farming, raising crops and animal husbandary.

Angiology: Study of blood vascular system including veins and arteries.

Anthology: Study of flowers.

Bacteriology: Study of bacteria.

Bryology: Study of mosses and liverworts.

Cardiology: Study of heart.

Dermatology: Study of skin covering the body.

Epidemiology : Study of infection of parasites or epidemic diseases.

Ethnology: Study of different races of mankind.

Etiology: Study of cause of disease. **Gerontology**: Study of growing old.

Gynaecology: Study of female reproductive organs.

Haematology: Study of blood.

Hepatology: Study of liver.

Kalology: Study of human beauty.

Leprology: Study of leprosy.

Molecular biology: Study of life sciences on molecular level

(e.g, nucleic acids i.e., RNA & DNA and proteins).
Myrmecology: Study of ants and anteaters.

Nematology: Study of nematodes. **Nephrology**: Study of kidney.

Neurology: Study of nervous system including brain.

Oncology: Study of tumours.
Oology: Study of eggs of birds.
Ornithology: Study of birds.
Osteology: Study of bones.

Palaeontology: Study of fossils and their distribution.

Pomology: Study of fruit.

Rhinology: Study of nose and olfactory organs.

Serology: Study of serum, Study of antigen-antibody reactions.

Serpentology: Study of snakes. **Termitology:** Study of termites.

Toxicology: Study of toxic effects of drugs and harmful compounds.

Therapeutics: Science of healing.
Trophology: Study of nutrition.
Virology: Study of viruses.

Zoophytology: Study of drifting organisms such as diatoms.

Zymology: Study of fermentation processes.

Fathers of Various Sciences

Father of Zoology and Biology and Founder of Embryology: Aristotle

Father of Botany: Theophrastus Father of Genetics: G.J. Mendel Father of Evolutionary ideas : Empedocles

Father of Eugenics : Francis Galton Father of Mutation : Hugo de Vries

Father of Modern Embryology: Karl Ernst Von Baer

Father of Palaeontology: Leonardo da vinci

Father of Taxonomy: Carolus Linnaeus

Father of Special Creation Theory: Father Saurez

Father of Blood groups : K.Landsteiner

Father of Blood circulation: William Harvey

Father of Comparative Anatomy : G. Cuvier

Father of Modern Genetics: W.Bateson

Father of human genetics : Archibald Garrod

Father of Medicine: Hippocrates

Father of Microbiology : Leeuwen hoek Father of Immunology : Edward Jenner

Biology in Ancient India

About 740 plants and 250 animals have been mentioned in Vedic literature. Few significant references in old literature are,

- (1) **Chandyogya Upanishad**: Here the animals have been classified into three categories
 - (i) Jivaja (Viviparous) e.g. mammals.
 - (ii) Andaja (Oviparous) e.g. birds, reptiles, insects and worms.
 - (iii) Udbhija (Vegetal origin) e.g. small animals.
- (2) **Susruta Samhita** (600 B.C.) : Here organisms were classified into,
- (i) **Sthavara** in which immobile organisms like plants were kept.
- (ii) Jangama in which mobile organisms like animals were placed.

Medical Science in Ancient India

Two Ashwini Kumars has been said to be practising medicine during Vedic times. Dhanvantari has been called as 'God of medicine'. Susruta has been called as 'Father of surgery'. Few important references are

- (1) Susruta studied human anatomy on dead bodies.
- (2) Susruta carried plastic surgery on human nose (rhinoplasty).
- (3) Ophthalmic surgery: Susruta carried an eye surgery like extraction of cataracts.
- (4) Clotting of blood: Susruta used non-poisonous live leeches for checking clotting of blood in post operative conditions. Now its clearly established that hirudin is released along saliva of leeches to produce this kind of effect.
- (5) **Charaka Samhita** (100 B.C.): It is said to be primarily written by Agnivesa under the guidance of Atreya (600 B.C.). Charaka was first to discuss the concepts of digestion, Metabolism and immunity.

Scope of Biology

Biology creates an awareness of vast array of forms of life which normally goes unseen. Biology offers a large scope and provides a large field for study.

- (1) **Helps us to understand ourselves better:** It unfolds different queries of life alongwith its cultural, social, philosophical and economical aspects. So it helps in understanding the life better.
- (2) **Biology and inter-relationship of living beings:** Study of biology helps us in understanding the wonderful phenomenon and laws of nature which finally tell us to predict the behaviour of different living beings under changed conditions.
- (3) **Biology and resources**: Biology helps us to know how to trap and conserve the resources available to us *e.g.* fishes, birds, forests etc.
- (4) **Biology and literature**: Knowledge of Natural Biology has greatly enriched the literature with their references in stories and poems etc. Poets and other authors have been inspired by the beautiful and interesting plants and animals and frequently figure them in stories, poems and dramas.
- (5) **Study of nature is a rewarding experience :** Many plants like *Narcissus, Dahlia, Gloriosa*, Roses, Marigold, Aster, etc. are used for ornamental purposes. The variety available in animals is widely enjoyed in zoological parks.

- (6) Solving problems: Biology makes us to understand the present day problems such as population growth, pollution, conservation of wildlife and survival of man etc. The future directions of biotechnology, conservation of biodiversity, maintenance of environment and human welfare remain in the hands of biologists.
- (7) **Biology-Medicinal aspect**: Several plants like Atropa belladona, Cinchona are sources of atropine, quinine etc. Many members of fungi such as Penicillium and Streptomyces give rise to antibiotics like penicillin and streptomycin. Plants are the major source of vitamins. Drugs are first tested on animals before being used for treating man. Animals provide scientific hints for the production and use of medicines. Many diseases like malaria are caused and transmitted by animals.
- (8) **Solving approach of biology**: Knowledge for eradication of diseases like malaria, small pox, etc. have been achieved by scientists basically due to desire and determination to solve the problem.
- (9) Ecosystem and living organisms: Biology helps us in understanding the various ecosystems. The living community and non-living environment interact with each other and exchange of material in them takes place.
- (10) Biotechnology: Biotechnologists have produced many genetically modified (GM) crops. Plenty of studies are being made by geneticists, evolutionists and cytologists to fudge the efficacy of biotechnology.

1.2 Understanding Life

Basic Properties of Living Organisms

Living beings are called organisms. Living organisms are similar to non-living objects in being – formed of similar elements which combine in similar way to form similar molecules (called biomolecules in living organisms) and follow similar physical and chemical laws like gravitation, magnetism, action and reaction etc. living organisms show a great biodiversity and are classified into different kingdoms-Monera, Protista, Fungi, Plantae and Animalia. But all of these share the following properties –

- (1) They have definite organisation.
- (2) They always have cellular nature so are either unicellular (e.g. Amoeba, Paramecium etc.) or multicellular (e.g., Hydra, man etc.).
- (3) They show co-ordination between different parts of body to maintain homeostasis (constant internal environment) inside the body.
 - (4) They have the ability of movements and locomotion.
 - (5) They show metabolic functions in the presence of energy.
- (6) These have the ability of intussusceptional (internal) growth and development.
- (7) These have specific receptors (e.g., sense organs to receive external and internal stimuli) and specific effectors (e.g., muscles and glands to give specific response).
- (8) These have regulatory mechanisms (e.g., nerves and hormonal in animals, and only hormonal in plants) to maintain homeostasis inside the body.
- (9) These show adaptations to their environment to increase their chances of survival.

- (10) These show variations which help in speciation and evolution.
- (11) These have reproductive powers for continuity of their race.

Levels of Biological Organization

- (1) Levels of Organization common in both living and non-living
- (i) **Atomic level:** The lowest level of organization in both living and non-living is the atom. All living organisms are basically made up of four chemical elements carbon (C), hydrogen (H), oxygen (O) and nitrogen (N) with only about 1% other elements. The non-living matter may possess other elements (such as silica, calcium, iron, etc.) in variable composition.
- (ii) Molecular level: Atoms combine to form molecules, which undergo chemical reactions to form organelles.

Atoms \rightarrow Molecules \rightarrow Inorganic compounds \rightarrow Simple organic compounds \rightarrow Complex organic compound \rightarrow Protoplasm \rightarrow Cell.

(2) Levels of Organization found only in living organisms

- (i) Cellular level: All multicellular organisms are made up of cells. The cell is considered as basic unit of life and constitutes the smallest level of organisation of the living organisms.
- (ii) **Tissue level**: In multicellular organisms similar or dissimilar cells, having a common origin and a common function, combine to form a tissue. Each tissue performs a specific role (e.g., xylem conducts water and minerals in plants).
- (iii) Organ level: Different tissue are organised to form distinct organs. For example, xylem, phloem chlorenchyma, parenchyma get organised to form a leaf.

- (iv) Organs System level: A group of organs that coordinates to performs a major function forms the organs system. For example, the brain works with the spinal cord and a network of nerves to form the nervous system.
- (v) **Individual or Organismic level :** A multicellular individual, having many organ systems, forms an organismic level of organisation.

 $Cell \rightarrow Tissue \rightarrow Organ \rightarrow Organ system \rightarrow Individual.$

- ${\footnotesize \mbox{(3) Levels of organization beyond the individual}} \label{eq:condition}$
- (i) Population level: All the individuals of a species in a particular area, where they interact with each other, belong to a population. For example, there is a population of Oak trees in a temperate deciduous forest.
- (ii) Community level: The populations of different species of plants and animals present in a particular area make up biotic community.
- (iii) **Ecosystem level**: Populations of different plants and animals interact among themselves and with the non-living components of the area form as ecosystem.
- (iv) Biosphere level: The different ecosystems (small or big) of all the geographical regions of the world form the biosphere or the entire livable part of the earth.

Building blocks of life and their function

Living organism is formed of many types of inorganic as well as organic biomolecules. Inorganic compounds include water, minerals etc. and are always micro-biomolecules (small sized, low molecular weight, readily soluble in water and diffusible) while organic molecules may be micro (e.g. monosugars, amino acids etc.) or macro-biomolecules (large sized, high molecular weight, insoluble or slightly soluble and non-diffusible e.g., proteins, fats, nucleic acids, etc.). These both types of biomolecules play important roles in metabolism:

- (1) **Role of Water**: Water forms 70-90% of the cellular pool. It forms 65% (about two-thirds) of human body. It is formed of H and O in the ratio of 2:1. 95% of water is found in free state and 5% in combined form in the cell. Water helps in sustaining the life processes. So water is called elixir or cradle of lip as life is not possible in the absence of water.
- (2) **Role of Oxygen**: Oxygen is mainly utilized in aerobic cell respiration of the nutrients inside the mitochondria to produce energy-rich ATP molecules so is essential for life. In the absence of oxygen, only 5% of energy available is released.
- (3) Role of Sodium chloride (common salt–NaCl) : Sodium chloride plays important roles in metabolic functions of body especially when in ionic form.
- (4) Role of Carbohydrates: Carbohydrates are organic compounds formed of C, H and O generally in the ratio of 1:2:1. These are commonly called saccharides (Gk. saccharon = sugar) Carbohydrates are the main storage molecules and most organisms use carbohydrates as an important fuel, breaking these bonds and releasing energy to sustain life.
- (5) Role of Proteins: Proteins are polymeric compounds formed by interlinking of amino acids (monomers) by peptide

- bonds. Out of about 100 types of amino acids, only 20 types of amino acids are of biological importance, so are called Magic-20. Proteins play a vital role in the formation of structures in living organisms. Like carbohydrate and fat, protein can be broken down with the release of energy. Protein is not stored as such in the body and it is normally only used as a substantial source of energy in conditions of starvation.
- (6) **Role of lipids**: Lipids comprise a major group of insoluble hydrocarbons having many functions. These are polymers of alcohols (e.g. glycerol) and fatty acids interlinked by esterbonds.
- (7) **Role of Nucleic Acid**: These are polymers of nucleotides interlinked by phosphodiester bonds, so called polynucleotides. Each nucleotide is formed of 3 components: a pentose sugar (e.g. ribose in RNA and deoxyribose in DNA), a phosphate group and an inorganic nitrogen-base (a purine or a pyrimidine).

Matter and Energy

Technically speaking, matter and energy are interchange able as expressed by Albert Einstein's famous equation $E = mc^2$: energy equals mass times the square of the speed of light (c^2) .

For the chemical reactions that occur within living organisms, however, we can treat matter and energy as quite distinct from one another. Matter is the physical material of the universe; energy is the capacity to do work.

Close and Open system: A system is a portion of the universe that is selected within a definite boundary. The part other than the system is called surrounding.

As system is said to be closed if it can exchange energy but not matter, and in this energy can be gained or lost (through stainless walls) but not matter. A system said to be open if it can exchange matter and energy with surroundings. All living systems are open systems because they are continuously exchanging matter and energy with their surroundings.

Kinetic and Potential energy

Kinetic energy is the energy of movement and this include not only movement of large objects but also movements such as electrical energy (movement of electrons) and heat (movement of atoms and molecules).

Potential energy is stored energy that can be released as kinetic energy under right conditions.

The food which you eat has chemical potential energy, some of which is converted into kinetic energy.

Laws of Thermodynamics

The laws of thermodynamics describe the basic properties of energy. All interactions among pieces of matter are governed by the two laws of thermodynamics. The laws of thermodynamics deal with "isolated systems" which are any parts of the universe that cannot exchange either matter or energy with any other parts.

First Law of Thermodynamics : The first law of thermodynamics states that energy can neither be created nor destroyed; but energy can change from one form to another.

In other words, within an isolated system the total quantity of energy remains constant. The first law is therefore often called the law of conservation of energy.

UNIVERSAL BOOK DEPOT 1960

Second law of Thermodynamics: The second law of thermodynamics states that the amount of useful energy always decreases when energy is converted from one form to another.

In other words, every transfer or transformation of energy makes the universe disordered; no physical process or chemical reaction is 100 per cent efficient.

Entropy is a measure of the disorder or randomness within a system.

Energy flow

- (1) **Energy Transformation**: It is the phenomenon in which one form of energy is changed into another form of energy, e.g. in photosynthesis (anabolism), radiant (Kinetic) energy of sunlight is changed into chemical (potential) energy of glucose. All the living organisms depend upon this transformation.
- (2) Energy Transfer: It involves the movement of energy from one source or area or substance to another in the same form. e.g. in cell respiration (catabolism), oxidative break down of glucose occurs inside the mitochondria of aerobic plants and animals.

The glucose is enzymatically catabolised by stepped breakdown into water and CO_2 and about 686 kcal of energy is released per mole of glucose. A part of released energy is stored as chemical energy in high energy bonds of ATP (adenosine triphosphate) formed by phosphorylation of ADP.

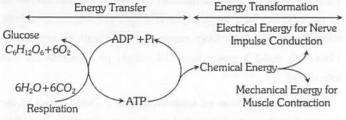

Table: 1.1-1 Some examples of Energy transformation.

Type of Energy Transformation	Example
Chemical to electrical	Nerve cell
Light to electrical	Retina of eye
Chemical to osmotic	Kidney
Chemical to mechanical	Muscles and cilia
Sound to electrical	Ear
Chemical to light	Bioluminescence
Chemical to heat	Homeothermy

Homeostasis

Homeostasis (Gk, homoios = same; stasis = standing) is the maintenance of a constant internal environment or steady state (blood plasma, haemolymph, extracellular fluid, etc.). The French physiologist Claude Bernard (1857) realized the importance of stability in the internal environment (milieu interieur). The term 'homeostasis' was first coined by the American physiologist Walter Bradford Cannon in 1929. Homeostasis is a fundamental property of life and is considered a good sign of life.

Thermoregulation

Regulation of body heat in response to the internal and external environment of the body is called thermoregulation.

As far as temperature regulation is concerned, animals can be divided into two groups: poikilothermous and homeothermous.

Poikilothermic means 'having a variable temperature'. Poikilothermic animals are described as 'cold-blooded', their body temperature changing with fluctuation in the environmental temperature. Homeothermic means 'having the same temperature'. Homeothermic animals (mammals, birds and a few fishes like tuna fish and sword fish) are popularly described as 'warm-blooded'; their body temperature is independent of environmental temperature.

Growth

Growth is one of the most important characteristics of living organisms. Growth is defined as a permanent increase in size or weight or volume of an organism or its body parts e.g. kittens grow into cats, puppies grow into dogs and a human baby grows to become adult.

At the molecular level, the growth involves,

- Increase in the size of cells due to synthesis of protoplasmic substances like cytoplasm and nucleus.
- (2) Addition of non-living aprotoplasmic materials like intercellular matrix, fibres of connective tissue, etc. These are secreted by the cells.
- (3) Increase in the number of cells by cell division. It occurs through cell cycle which is formed of interphase and M-phase.
- (4) Growth is the result of greater anabolic (synthetic) processes over the catabolic (destructive) processes in an organism.

The process in which reserve food material is utilized and exhibited negative growth is called degrowth.

Development

- (1) In general, growth involves three processes or strategies namely cell proliferation, cell enlargement and secretion of large amount of extra cellular matrix.
- (2) Growth is an important part of development, continuing throughout life.
- (3) Early embryonic developmental stages constitute prefunctional state of life.
- (4) The biological process of growth and differentiation enables the animal to enter the functional state of life.
- (5) Morphogenesis refers to generation of form and structure during development of an individual organism.
- (6) Morphogenesis produces new forms by involving cell movements.
- (7) Morphogenetic movements of large number of cells during development is particularly noticed during gastrulation.
 - (8) Differentiation results in increasing diversity of cells.

Reproduction

- (1) Reproduction is one of the most important life functions.
- (2) Reproduction is the only way that living things can perpetuate themselves.
- (3) There are a number of different ways that various kinds of organisms reproduce and compensate for the loss of life due to death.
- (4) Some reproductive processes known as sexual reproduction involve two organisms and their sex cells.
- (5) Asexual reproduction occurs when organisms make identical copies of themselves.

Adaptation

- (1) Adaptation may be defined as any characteristic of an organism which makes the organism better suited to its environment.
- (2) In other words, an adaptation improves the performance and survival of the organism in its the environment.
- (3) Individuals with favourable characteristics replace those with less favourable characteristics.
- (4) Adaptation improves the match between organisms and their environment.
- (5) On the basis of their nature and role in evolution the adaptation are classified into short range or temporary and long range or permanent adaptation.

Life Span

The average longevity of an organisms from birth to death is called life span. It is different in different living organisms. **Death**

Death is the permanent breakdown and finally stopping of vital functions of body, especially heart beat and respiration.

Characteristics

- (1) It is the last event in the degenerative processes of ageing.
- (2) Death involves widespread cell breakdown and cell death.
- (3) Death of an organism involves the death of body cells. But all the body cells do not die at same rate e.g. ciliated cells lining the respiratory tract of mammals continue to beat their cilia for long time even after clinical death.
- (4) There is no natural death in some protists e.g. Amoeba and monerans like bacteria, etc.

Taxonomy

The art of identifying distinctions among organisms and placing them into groups that reflect their most significant features and relationship is called biological classification. Scientists who study and contribute to the classification of organisms are known as systematists or taxonomists, and their subject is called systematics (Gk. Systema = systems or order or sequence) or taxonomy (Gk. Taxis = arrangement; nomos = law).

Classical taxonomy: Taxonomy based on all available information and attempting to classify organisms, according to their origin, evolution and variations is called classical taxonomy. A taxonomist engaged in studying origin, evolution, variations and classification of organisms is called classical taxonomist.

History of classification

References of classification of organisms are available in **Upanishads** and **Vedas**. Our Vedic literature recorded about 740 plants and 250 animals. Few other significant contributions in the field of classification are :

Chandyogya upanishad: In this, animals are classified into three categories-viviparous *Jivaja*, oviparous *Andaja* and minute *Udbhija*.

Susruta samhita : It classified all 'substances' into **sthavara** (immobile) *e.g.*, plants and **jangama** (mobile) *e.g.*, animals.

Parasara: Here, angiosperms were classified into dvimatruka (dicotyledons) and ekamatruka (monocotyledons).

He was even able to find that dicotyledons bear **jalika parana** (reticulate veined leaves) and monocotyledons bear **maun laparna** (parallel veined leaves).

Hippocrates and Aristotle : They classified animals into four major groups like insects, birds, fishes and whales in his *Scala naturae*.

Nomenclature

Nomenclature is the assignment of a distinctive name to each species. Almost all plants (and animals too) are known by different common names in different parts of the world. Even within the same country people of different states and regions use different common names.

Ipomoea batatas, for example, is called **sweet potato** in English, **Shakarkandi** in Hindi, **Meetha alu** in Assamies and Bengali, **Kundmul** in Telagu, **Ratalu** in Marathi and **Jenasu** in Kannad. Similarly, the common house sparrow is called "Goraiya" in India, "Sparrow" in England and "Haussperling" in America. The common names are thus quite confusing.

The earliest scientific names were **polynomial**, i.e., they were composed of many words (which gave the characteristics of plants), e.g., Sida acuta (a member of Malvaceae) was named as Chrysophyllum folis, ovalis superne glabris parallel striatis subtus, tomentosonitidis such long names were difficult to remember. Hence, to make it easier binomial system of nomenclature was introduced.

Binomial system of nomenclature: The credit of giving binomial system of nomenclature goes to Swedish naturalist, Carolus Linnaeus. He employed this system in his book Species Plantarum, published in 1753. According to this system the name of a plant or animal is composed of two Latin (or Latinised) words, e.g., potato is Solanum tuberosum and house sparrow is Passer domesticus. The first word (i.e., Solanum) indicates the name of the genus (called generic name) and the second word (i.e., tuberosum) denotes the name of the species (or a specific epithet). The generic name always begins with a capital letter and the specific name with a small letter and printed in italics.

The generic and specific names always have some meaning. They are based on some special characters of the plant and animals, on the name of any scientist or on some legend.

Usually the name of the author, who names a organism, is also written in full or in abbreviated form after the specific name. Thus, in case of Mangifera indica L., the L. stands for Linnaeus and in Lychnis alba Mill., the Mill. stands for Miller.

Sometimes a single species is described under different names by different authors. These names are called **synonyms**. In such cases, the name under which the species is first described, is considered to be valid.

Trinomial nomenclature: Certain species are divisible into smaller units, called subspecies or varieties, on the basis of finer differences. The name of the variety is written after the specific name. Thus, the name may become trinomial or three word name. e.g., Homo sapiens europeus is the name of the man of European race. Trinomial nomenclature is simply an extension of the Linnaean system.

Code of biological nomenclature: Anyone can study, describe, identify and give a name to an organism provided certain universal rules are followed. These rules are framed and standardised by International Code of Botanical Nomenclature (ICBN) and International Code of Zoological Nomenclature (ICZN). The codes help in avoiding errors, duplication, confusion and ambiguity in scientific names. The codes are established and improved upon at International Botanical and Zoological Congress held from time to time. The names of bacteria and viruses are decided by International Code of Bacteriological Nomenclature (ICBN) and International Code of Viral Nomenclature (ICVN). Similarly, there is a separate International Code of Nomenclature for Cultivated Plants (ICNCP).

Valid name

- It is not a tautonym (e.g., same generic and same specific name).
- (2) The name is new and given according to binomial nomenclature with abbreviation of author's name.
 - (3) Its type specimen has been described in latin.
- (4) The type specimen is kept in a recognised herbarium/collection.
- (5) The new name has been published in a widely circulated scientific journal.
- (6) All the names previously given to the organism must be indicated.
- (7) If the new name is higher than species, the taxonomic category is indicated.

Type of specification

Holotype: The original type specimen from which the description of a new species is established.

Isotype: Duplicate of holotype, as another branch of the same tree.

Lectotype: Specimen selected from original material to serve as nomenclatural type where there is no holotype.

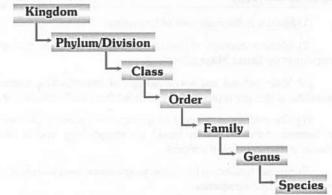

Neotype: New nomenclatural type when the original type is missing

Paratype: Any other specimen described along with holotype.

Syntype: Any of two or more specimens cited by an author when there is no holotype.

The taxonomic hierarchy

It is the sequence of arrangement of taxonomic categories in a descending order during the classification of an organism. Hierarchy was first given by Linnaeus who used only five categories – class, order, genus, species and variety. The last one was discarded and three added so that now there are seven **obligate categories**. They are:

Some categories have been added to this list. They are called **intermediate categories**, *e.g.*, Subkingdom, superphylum or superdivision, subdivision, superclass, subclass, superorder, suborder, superfamily, subfamily, tribe, subspecies, variety etc.

Taxon: Term taxon was introduced by ICBN during 1956 and defined by Mayr (1964). The term taxon is used to represent any unit of classification. The unit (i.e., taxon) may be large (e.g., Plant Kingdom) or small (e.g., Algae, Fungi, or a single species).

Category: Various sub-divisions of plant kingdom such as division, class, order, family, etc., are referred to as categories. In the hierarchy of categories, kingdom is the highest and species is the lowest category. The following is hierarchical series:

- (1) **Kingdom**: It is the highest category in biological classification. *e.g.*, all plants are included in plant kingdom.
- (2) **Division (Eichler or phylum)**: It is a major group in the Linnaean hierarchy used in the classification of plants (equivalent to phylum in animal classification). It is a taxonomic category between kingdom and class. The subcategory of division is **subdivision**. The suffix of division is phyta.
- (3) Class (Linnaeus, 1735): A division is divided into classes. It is a taxonomic category between the division and order. Its suffix is ae. The subcategories of class are subclass and series. The class contains organism least similar to one another.
- (4) **Order (Linnaeus, 1735)**: A class includes one or more orders. It is a taxonomic category between the class and family. Its suffix is ales. The subcategory of order is **suborder**.
- (5) Family: An order is divided into one or more families. It is the taxonomic category between the order and the genus. Its suffix is aceae. The subcategories of family are subfamily (Suffix-oideae), tribe and subtribe.
- (6) Genus: The plural of genus is genera. It comprises a group of related species which has more characters in common in comparison to species of other genera. The subcategories of genus are subgenus, section and subsection.

(7) **Species (John Ray, 1693)**: It is the smallest rank and basic unit of taxonomic classification. The first letter of the species is denoted with small letter. The species is printed in Italics (It is underlined if hand written). A genus may include one or more species. The subcategories of species are **subspecies** or **varieties, subvarieties, form** and **subform**.

Species concept

- (1) Species is the basic unit of taxonomy.
- (2) Modern concept of species is biological species concept introduced by **Ernst Mayr** (1942).
- (3) Mayr defined species as groups of interbreeding natural populations that are reproductively isolated from each other group.
- (4) The traditional concept of species was given by Linnaeus in *Systema naturae*; this is based on morphology and is also known as 'Morphological concept'.
- (5) Species inhabiting the same geographical area (identical or overlapping) are **sympatric**.
- (6) Species inhabiting different geographical areas are allopatric.
- (7) Related species which are reproductively isolated but morphologically similar are called **sibling species**.
- (8) Classical systematic is based on the 'Typological concept' by **Plato** and **Aristotle**.
- (9) Genetic species concept was given by Lotsy (1918), according to which, a species is a group of genetically identical individuals.
- (10) Species that contain two or more subspecies are called **polytypic species**.
- (11) Species that are not sub-divided into subspecies are called **monotypic species**.
 - (12) Normally breeding is possible only within a species.
 - (13) Two different species are reproductively isolated.

System of Biological Classification

Different systems of classification proposed from time to time have been divided into three basic categories *viz.*, artificial systems, natural systems and phylogenetic system (However, Redford, (1986), included mechanical systems as a fourth category).

(1) **Artificial system of classifications**: These systems are more or less arbitrary as the plants are classified merely on the basis of gross morphology, habit and their importance to man. The main advocates of artificial system of classifications were:

Aristotle : He also classified animals on the basis of habitat into water, land and air.

Theophrastus (370 B.C. to 285 B.C.): Theophrastus was a disciple of Plato and later Aristotle. In his book *De Historia plantarum*, he classified about 500 kinds of plants into four major group; trees, shrubs, subshrubs and herbs.

John Ray: He was a British botanist who published three volumes of his work *Historia Generalish Plantarum* consisting of improved classification originally proposed by him in *Methodus Plantarum Noven*. He was the first to divide the groups herbs,

shrubs and trees into Dicots and Monocots on the basis of the presence of two or one cotyledons respectively. He coined the term **species**.

Carolus Linnaeus: Father of taxonomy. A Swedish botanist, who published an artificial system of classification based exclusively on floral characters. Linnaeus published several manuscripts including Hortus cliffortianus and Genera plantarum (1737). In his Genera plantarum he listed all the plant genera known to him. He published his best known Species plantarum in 1753. In this book he listed and described all species of plants known to him. He established binomial nomenclature.

(2) Natural system of classifications: These systems of classification are based not only on the characters of reproductive organs and structural morphology but used as many taxonomic characters or traits as possible to classify the organisms. The advocates of **natural** systems of classification are listed below:

Carolus Linnaeus : The first natural system of animal classification was developed by Linnaeus in his book "Systema Naturae" (10th edition 1758). Improvements were subsequently made by Haeckel (1864) and Lankester (1874).

George Bentham (1800-1884) and Joseph Dalton Hooker (1817-1911): These two English botanists classified plants based on original studies of specimens. They published their well known scheme of classification in *Genera plantarum* (1862–83). This system of classification is still regarded as the best classification, especially from the practical point of view.

- (3) Phylogenetic system of classifications: These systems of classifications are mainly the rearrangements of natural systems using as many taxonomic characters as possible in addition to the phylogenetic (evolutionary) informations. Some important phylogenetic systems of classifications were proposed by:
- **A.W. Eichler (1839-1887)**: A German botanist who proposed phylogenetic system of classification and published in the third edition of *Syllabus der vorlesungen* (1883).

Adolph Engler (1844-1930) and Karl Prantl (1849-1893): These two German botanists classified plant kingdom on the basis of their evolutionary sequences. They started with simplest flowering plants and ended with plants of complex floral structures.

C.E. Bessey (1845-1915) : He classified flowering plants on the basis of their evolutionary relationships.

John Hutchinson (1884-1972) : A British botanist published his phylogenetic system of classification in 'The Families of Flowering Plants'.

Armen Takhtajan (1980) : A Russian botanist who published his system of classification in *Botanical Review*.

Arthur Cronquist (1981) : Published his classification in 'An Integrated System of Classification of Flowering Plants'.

Phylogenetic systems of classification for animals given by Dobzhansky and Mayr.

New Systematics or Biosystematics

The term new systematics was proposed by Sir Julian Huxley in 1940. In the new systematics, the species are considered related to one another, mutable and the work of gradual modification. This is in conformity with the facts of evolution.

Forms of new systematics: There are several forms of new systematics:

- Morphotaxonomy: It is based on the structural features of the organisms.
- (2) **Cytotaxonomy**: It is based on cytological information of cell, chromosome number, structure and behaviour of chromosome during meiosis. **Karyotaxonomy** is a branch of cytotaxonomy which is based on banding pattern of chromosome.
- (3) Biochemical taxonomy or Chemotaxonomy: It is based on the protein and serum analysis and on the chemical constituents of the organisms.
- (4) Numerical taxonomy: It involves quantitative assessment of similarities and differences in order to make objective assessments. Characters of organisms are given equal weight and the relationships of the organisms are numerically determined, usually with the aid of a computer.
- (5) **Experimental taxonomy**: It is based on the genetic relationship determined with the help of experiments.

Modern trends in systematics

Two kingdom system of classification: This system of classification is the oldest it was suggested by *Carolus Linnaeus* in 1758. He divided the living world (organism) into two kingdoms, Plantae (for all plants like tree, shrubs, climbers, creepers, moss and floating green algae) and Animalia (for animals).

Three kingdom system of classification: Ernst Haeckel, a German biologist and philosopher, suggested a third kingdom protista in 1866 for:

- (1) Unicellular organisms such as bacteria, protozoans and acellular algae.
 - (2) Multicellular organisms without tissue such as algae and fungi.

Four kingdom system of classification: It was proposed by Copeland in 1956. The two additional kingdoms were Monera for the bacteria and blue green algae and Protista for protozoans, algae and fungi.

Five kingdom system of classification : R.H. Whittaker, an American taxonomist. He proposed five kingdom system of classification in 1969.

This system replaced the old, two-kingdom grouping of living organisms. As already discussed, a division of living world merely into plant and animal kingdoms is too simple. It does not take into account the **gradual** evolution of distinct plant and animal groups and it allows no place for those primitive organisms that even now are neither plants nor animals nor that are both. In this classification eukaryotes were assigned to only four of the five kingdom.

Five-kingdom classification is based on the following five criteria:

- (1) Complexity of cell structure.
- (2) Complexity of organism's body.
- (3) Mode of obtaining nutrition.
- (4) Phylogenetic relationship.
- (5) Ecological life style.

The five kingdoms are: Monera, Protista, Fungi, Plantae and Animalia.

Monera: It includes all prokaryotic organisms, which may have autotrophic or heterotrophic type of nutrition and are surrounded by a rigid cell wall. They are usually unicellular ranging from one to a few micron size. They are important decomposers and mineralizers. It include Bacteria, Actinomycetes, Cyanobacteria, etc.

Protista: They are mostly aquatic unicellular organisms, having eukaryotic organization. They generally have cilia or flagella and have diversified mode of life. Most of them are photosynthetic autotroph but some are holozoic, parasitic or even symbiotic. *e.g.*, Euglena.

Fungi: They are diversified eukaryotic, heterotrophic organisms, body of which is made up of filamentous mycelium. They generally grow as saprophytes or parasites. They include moulds, mushrooms, puff balls etc.

Plantae: It includes all multicellular photosynthetic plants, which may have red, brown or green pigmentations except a few parasitic, saprophytic and insectivorous types. Most of the members are primary producers of land and water (Phaeophyta, chlorophyta, bryophyta, tracheophyta etc.).

Animalia : They are multicellular eukaryotic organisms having holozoic type of nutrition. They show muscular contractility and have a nervous system.

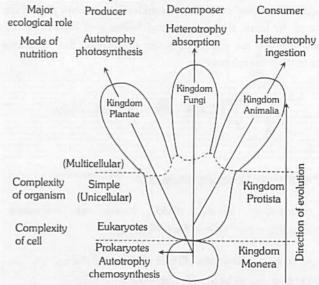

Fig :1.1-1 Probable phylogenetic relationships among the kingdoms

Taxonomic Aids: Taxonomists collect specimens from the field, preserve and store the same for later verification and reference. Studies are carried out both in the field as well as inside the laboratory. Botanical gardens, herbaria, museums and zoological parks are important aids in taxonomic studies.

Monograph: It is a book or essay which gives comprehensive account of all the available information about a

genus, family or higher category (or any other particular subject) of grouping at the time of its publication. It is a highly useful taxonomic aid.

Herbarium : Herbaria are collections of dry, pressed and preserved plant specimens mounted on sheets. Some plant parts are also kept in preservative liquids if they cannot be dried and pressed.

Botanical Gardens: These specialized gardens have collections of living plants for reference. Plant species in these gardens are grown for identification purposes and each plant is labelled indicating its botanical/scientific name and its family. The famous botanical gardens are at Kew (England), Indian Botanical Garden, Howrah (India) and at National Botanical Research Institute Lucknow (India).

Museum: Biological museums are generally set up in educational institutes such as schools and colleges. Museums have collections of preserved plant and animal specimens for study and reference. Plant and animal specimens may also be preserved as dry specimens. Specimens are preserved in the containers or jars in preservative solutions. Insects are preserved in insect boxes after collecting, killing and pinning. Larger animals like birds and mammals are usually stuffed and preserved. The largest museum in our country is Indian Museum at Kolkata.

Zoological Parks: These are the places where wild animals are kept in protected environments under human care and which enable us to learn about their food habits and behaviour. All animals in a zoo are provided, as far as possible, the conditions similar to their natural habitats.

Tips & Tricks

- Founder of Taxonomy : Aristotle.
- α-taxonomy (Turril, 1938) based on collections identification, compilation of fauna and flora.
- \varnothing (omega) taxonomy (Turril, 1938) : It brings out the correct relationships as in new systematics.
- E Cladistics is a method of classification (given by Willi Hennig) in which plants/animals are placed into taxonomic groups (called clades) according to their phylogenetic/ evolutionary relationships.
- Cladogram : Tree like graphic representation of evolutionary history of organism.
- Dendrogram: When cladogram is based on numerical taxonomy it is called dendrogram.

- Tribe: An intermediate category which is used in between genus and sub family.
- Cohort: Used differently by different authors as (i) Group of related species (ii) Group between order and class and (iii) Group above the rank of super-order.
- Taxonomic key: It is a set of alternate characters of different types arranged sequence wise in such manner that by selection and elimination one can quickly find out the same organism. It is of two type: (a) Bracketed key (b) Indented or yolked key.
- Floral characters are used as basis of classification and for identifying new species because floral characters are conservative when compared with vegetative characters.
- In Bentham and Hooker's classification Dicotyledons have been kept before Monocotyledons. Seed plants have been divided into Dicots, Gymnospermae and Monocots.
- Among the vegetative characters, venation in leaf in one of highly acceptable character for classification of angiosperms.
- The correct sequence of taxa in Linnaean hierarchy is species → genus → family → order → class.
- Bauhin (1623) proposed the binary system of nomenclature which was elaborated by Linnaeus (1753) into binomial system.
- Monotypic genus: A genus having only one species, e.g., Homo.
- Polytypic genus: A genus containing more than one species, e.g., Panthera, Solanum.
- Engler and Prantl wrote 'Die naturlichen pflanzen familien' which contained the first phylogenetic classification.
- J.K. Maheswari described the plants of India in 'Flora of Delhi'.
- Camerarius was the person, who first recognized sexuality in plants.
- In Bentham and Hooker's system of classification, evolutionary criteria have not been followed hence not phylogenetic.
- Phylum covers the largest number of organisms.
- Hooker compiled first complete flora of India and wrote the book 'Flora of British India'.
- The prokaryotes and eukaryotes were distinguished by Dogherty (1957).

Bioinformatics is an interdisciplinary branch which is

concerned with the application of

	evolution evolution		nomenclature and identification of plants is [NCERT]
	(c) Reproduction		(a) Systematic Botany (b) Ecology

(c) Reproduction

(d) Growth and movement

BOOK	DEPOT 1960			
3.	Which one of the following is not a correct statements	13.	A group of plants with similar	
	[NEET 2013]			T 1990, 92, 96, 97; AFMC 1994;
	(a) Key is taxonomic aid for identification of specimens		CPMT 1996;	Chd. CET 2000; Pb. PMT 2002;
	(b) Herbarium houses dried, pressed and preserved plant		(a) Species	DPMT 2006; Odisha JEE 2009] (b) Genus
	specimens		(a) Species (c) Order	(d) Taxon
	(c) Botanical gardens have collection of living plants for	14.		hierarchical group, in which one
	reference	14.	of the following the largest i	number of species is found
	(d) A museum has collection of photographs of plants and			[WB JEE 2012]
	animals		(a) Genus	(b) Order
4.	A person who studies about the origin, evolution and		(c) Family	(d) Cohort
	variations in plants and also about the classification of plants, is called as [NCERT; AIIMS 1992]	15.		of plants[NCERT; MP PMT 1993]
	(a) Classical taxonomist (b) Herbal taxonomist		(a) Genus is written after the	
	(c) α -taxonomist (d) β -taxonomist		(b) Both in genus and spec	ies the first letter is a capital letter
5.	ICBN stands for [NCERT; MP PMT 2003;		(c) Genus and species may	y be same name
٠.	BVP 2004; CBSE PMT 2007]		(d) Both genus and species	s are printed in italics
	(a) International Council for Botanical Nature	16.	Match the following	
	(b) International Code of Botanical Nomenclature		(A) Genera Plantarum	(1) Aristotle
	(c) Indian Code of Botanical Nomenclature		(B) Species Plantarum	(2) Linnaeus
	(d) None of the above		(C) Historia Generalis	(3) Bentham and Hooker
			Plantarum	
6.	Who amongst the following is regarded as the "Father of Taxonomy" [NCERT; DPMT 1992; MP PMT 1997;		(D) Scala Naturae	(4) Pliny
	HPMT 1998; WB JEE 2012]			(5) John Ray
	(a) Takhtajan (b) Linnaeus			[CBSE PMT 1999, 2001;
	(c) Bentham and Hooker (d) Theophrastus		AIEEE Ph	armacy 2004; Odisha JEE 2004;
7.	If a botanist has to nomenclate a similar species, he will use			WB JEE 2008: VITEEE 2008]
	[CPMT 1999; JIPMER 2001]		(a) A-4, B-2, C-5, D-	-3
	(a) Syntype (b) Neotype		(b) A-4, B-2, C-1, D-	-3
	(c) Mesotype (d) Isotype		(c) A-4, B-2, C-3, D-	-1
8.	Which of the following taxonomical ranks contain organisms		(d) A-3, B-2, C-5, D-	-1
	least similar to one another	17.	The smallest taxon is called	
	[NCERT; DPMT 1999; Pb. PMT 2000]		[NCERT; J	& K CET 2008; MP PMT 2010, 11]
	(a) Class (b) Genus		(a) Class	(b) Order
	(c) Family (d) Species		(c) Genus	(d) Species
9.	In a hierarchical system of plant classification, which one of the	18.	The state of the s	n which a large number of traits
	following taxonomic ranks generally ends in 'ceae' [AFMC 2003]			; AIIMS 1996; CBSE PMT 1999]
	(a) Family (b) Genus		(a) Artifical system	(b) Synthetic system
	(c) Order (d) Class		(c) Natural system	(d) Phylogenetic system
10.	Which one of the following is a taxonomical aid for	19.		lassification what was positioned
	identification of plants and animals based on similarities and		in between dicots and mone	
	dissimilarities [Kerala PMT 2012]		(a) Gymnosperms	(b) Bryophytes
	(a) Flora (b) Keys		(c) Algae	(d) Pteriodophytes
	(c) Monographs (d) Catalogues	20.	Who proposed the Binomia	
11	(e) Manuals		[NCERT; RPM	T 1992, 98; CBSE PMT 1993, 94;
11.	When organism is in same class but is not in same family, the taxonomic term is called as [NCERT; Odisha JEE 2008]			2000; Pb. PMT 1998, 99, 2000;
	(a) Order (b) Genus			T 1999, 2000; J & K CET 2000;
	(c) Species (d) Family			IMS 2001; MHCET 2001, 02,04; 2003, 06; Odisha JEE 2004, 11;
12.	Which is a taxon [NCERT; CBSE PMT 1992; Pb. PMT 1998]			2003, 00; Odisha 3EE 2004, 11; 2004; BHU 2005, 06; AFMC 2010]
	(a) Genera (b) Family		(a) Whittaker	(b) Mendel
	(c) Class (d) None of these		(c) Carl Linnaeus	(d) Tippo
	(d) Holle of these			, , , , , , , , , , , , , , , , , , , ,

(d) Housefly, butterfly, tsetsefly, silverfish - Insecta

Five kingdom classification was proposed by New Systematics introduced by Sir Julian Huxley is also 30. [NCERT; Haryana PMT 1993; AFMC 1994; [Kerala PMT 2008] MP PMT 2000,06; MHCET 2001; BVP 2001; (a) Phenetics (b) Cladistics Kerala PMT 2004; Odisha JEE 2004; (c) Biosystematics (d) Numerical taxonomy J & K CET 2010; CPMT 2010] (e) Chemotaxonomy (a) Birbal Sahni (b) Whittaker 22. Binomial nomenclature system of Linnaeus means that (c) Aristotle (d) Oswald Tippo every organism has [NCERT; CBSE PMT 1993, 94; In Whittaker's 'Five Kingdom Classification', eukaryotes were 31. BHU 1994, 2002; RPMT 1995; CPMT 1995; assigned to [NCERT; BHU 1994; KCET 1999; APMEE 1995; EAMCET 1995; AMU (Med.) 1995; MHCET 2003; Odisha JEE 2005] DPMT 1996; Chd. CET 2000; Pb PMT 2000; (a) Only two of the five kingdoms MP PMT 2004, 06, 12; PET (Pharmacy) 2013] (b) Only three of the five kingdoms (a) One name given by two scientists (c) Only four of the five kingdoms (b) Two names one Latin and other of a person (d) All the five kingdoms (c) Two names one scientific and other popular 32. In five kingdom system, the main basis of classification is (d) One scientific name with generic and other with specific [NCERT; Manipal 2001; CBSE PMT 2002] epithet (a) Nutrition (b) Nucleus structure Which of the following is a merit in the Bentham and (c) Cell wall structure (d) Asexual reproduction Hooker's system of classification [Kerala PMT 2008] 33. Brinjal, potato, tomato, onion, ginger belongs to (a) The position of Gymnospermae in between dicots and [Odisha JEE 2009] monocots (a) Single family (b) Species (b) Closely related families are placed apart (c) Genera (d) Same genus (c) The placement of family asteraceae in the beginning of 34. Two kingdoms constantly figured in all biological gamopetalae classifications are [J & K CET 2008] (d) The placement of order ranales in the beginning (a) Plantae and animalia (b) Monera and animalia (e) The placement of orchidaceae in microspermae (c) Protista and animalia (d) Protista and plantae 24. Linnaeus system of plant classification is 35. Which of the following is grouped under phanerogams INCERT: MP PMT 1996, 97: [CBSE PMT 2000] AIIMS 1999; Kerala PMT 2004] (a) Pteridophytes (b) Gymnosperms (a) Artificial (b) Natural (c) Angiosperms (d) Both (b) and (c) (c) Phylogenetic (d) None of the above Single-celled eukaryotes are included in 36. [NCERT: 25. In plants Latin names are suggested because DUMET 2009; CBSE PMT (Pre.) 2010; BHU 2012] (a) Latin is a simple language (a) Monera (b) Protista (b) In whole world there would be only one name for one plant (c) Fungi (d) Archaea (c) It is easy to write 37. No. of plants species reported in India are [DPMT 2003] (a) 45,000 (d) Most of the names in other languages are not correct (b) 40,000 (c) 90,000 (d) 50,000 26. Specific epithet is [Odisha JEE 2012] 38. Genus is a group of similar and related [Pb. PMT 2000] (a) First word in the scientific name of a species (a) Order (b) Genera (b) Second word in the scientific name of a species (c) Families (d) Species (c) Both (a) and (b) 39. Which of the following is excluded in Whittaker's five (d) None of these kingdom system of classification [BHU 2012] Who did propose natural classifications of plants (a) Viruses (b) Algae [NCERT; CPMT 1992, 2009; MHCET 2002; (c) Fungi (d) Bacteria Odisha JEE 2004, 09; BVP 2004; KCET 2012] Systema Naturae is concerned with 40. [MP PMT 1998] (a) Carolus Linnaeus (b) John Hutchinson (a) Solar system (c) Bentham and Hooker (d) Oswald Tippo (b) Ecosystem 28. Who proposed phylogenetic classification of plants Classification of plants and animals (c) [NCERT: BHU 1991: (d) Natural selection CPMT 1998; Haryana PMT 2000; Pb. PMT 2004] Which of the following are correctly matched with respect to 41. (a) Linnaeus (b) Hutchinson their taxonomic classification **INEET 20131** (a) Spiny anteater, sea urchin, cucumber (c) Bentham and Hooker (d) Mehta sea Echinodermata Identify from the following, the only taxonomic category that (b) Flying fish, cuttlefish, silverfish – Pisces has a real existence. [KCET 2006] (c) Centipede, millipede, spider, scorpion - Insecta (a) Genus (b) Species

(c) Phylum

(d) Kingdom

(c) Historia naturalis

(d) Historia plantarum

42.	The meaning of taxon in the classification of animals	51.	Who developed the "key" for identification of animals
	[CBSE PMT 1996]		[MP PMT 1999]
	(a) A group of same species		(a) John Ray (b) Goethe
	(b) A group of animals on the basis of number of		(c) Georges Cuvier (d) Theophrastus
	chromosomes	52.	What is the name of the book written by Aristotle [MP PMT 1999; Pb PMT 1999]
	(c) A group of same type of animals		(a) Historia Animalium (b) Histoire Naturelle
	(d) A group of similar genera		(c) Systema Naturae (d) Philosophic Zoologique
43.	Most important criteria used for the present day classification of living organisms is based on [CBSE PMT 1991]	53.	The replacement of two kingdoms grouping by five
	(a) Presence and absence of notochord		kingdom classification was proposed in the year [Kerala CET 2003]
	(b) Resemblances in external features		(a) 1859 (b) 1758
	(c) Breeding habits		(c) 1919 (d) 1969
	(d) Anatomical and physiological characteristics	54.	Engler and Prantl published a phylogenetic system in
14.	The non-nucleated, unicellular organisms of Whittaker's		monograph [Kerala CET 2005]
	(1969) classification are included in the kingdom		(a) Die Naturlichen Pflanzen Familien
	[NCERT; MP PMT 1994; BHU 1997, 2012;		(b) Historia Plantarum
	Kerala PMT 2000; J & K CET 2008; AMU (Med.) 2010]		(c) Species Plantarum
	(a) Protista (b) Monera		(d) Genera Plantarum
	(c) Animalia (d) Plantae		(e) Origin of Species
45.	The suffix 'idae' refers to	55.	In the five-kingdom classification, Chlamydomonas and
	(a) Family (b) Genus		Chlorella have been included in
	(c) Order (d) Division		[NCERT; CBSE PMT (Mains) 2012] (a) Protista (b) Algae
16.	Read the statements given below and identify the incorrect		(c) Plantae (d) Monera
	statement [KCET 2012]	56.	Which structure is present in both prokaryotic and
	(a) Scientific names are used all over the world		eukaryotic plant cells [WB JEE 2008]
	 (b) Scientific names are often descriptive and tell us some important character of an organism 		(a) Cell wall (b) Nucleus (c) Chloroplast (d) Mitochondria
	(c) Scientific names indicate relationship between species	57.	Oryza sativa is the binomial name of the rice plant, the
	(d) Scientific names favour multiple naming for the same		sativa stands for [NCERT; WB JEE 2008]
	kind of an organism		(a) Specific name (b) Specific epithet (c) Species name (d) Specific nomenclature
17.	The term 'New systematics' was introduced in 1940 by	58.	Which of the following is considered as neither prokaryotes
	[AFMC 1993; AMU (Med.) 1999; BVP 2002]		nor eukaryotes [J & K CET 2010]
	(a) Adolf Engler (b) Karl prantl		(a) Bacteriophages (b) Bacteria
	(c) George Bentham (d) Julian Huxley		(c) Monera (d) Fungi
18.	Taxonomic hierarchy refers to [DUMET 2009]	59.	Interbreeding natural population of animals are referred to
	(a) Stepwise arrangement of all categories for classification		as belonging to the same
	of plants and animals		[NCERT; AMU (Med.) 2002; J & K CET 2010] (a) Family (b) Species
	(b) A group of senior taxonomists who decide the		(c) Genus (d) Variety
	nomenclature of plants and animals	60.	Natural system of classification is based on
	(c) A list of botanists or zoologists who have worked on		[NCERT; DPMT 1993]
	taxonomy of a species or group		(a) Morphology (b) Phylogeny
	(d) Classification of a species based on fossil record		(c) Morphology and affinities (d) Ontogeny
9.		61.	Which one of the following organisms is scientifically
9.	The third name of the trinomial nomenclature is of		correctly named, correctly printed according to the
	[NCERT; JIPMER 1993; APMEE 2001]		International Rules of Nomenclature and correctly described [NCERT; CBSE PMT (Mains) 2012]
	(a) Sub-genus (b) Species		(a) Musca domestica - The common house lizard, a reptile
	(c) Sub-species (d) Type		(b) Plasmodium falciparum - A protozoan pathogen
50.	In which book has "binomial nomenclature" been used for		causing the most serious type of malaria
	the first time [MP PMT 1999; Pb PMT 1999; Odisha JEE 2005]		(c) Felis tigris - The Indian tiger, well protected in Gir forests
	(a) Histoire naturelle (b) Systema naturae		(d) Fooli Full name Entampoha sell a commente

(d) E.coli - Full name Entamoeba coli, a commonly

occurring bacterium in human intestine

UNIVERSAL BOOK DEPOT 1960

Consider the following statements with respect to 73. A scientist having made significant contribution in the field characteristic features of the kingdom of classification is [CPMT 1990] A. In animalia the mode of nutrition is autotrophic (a) Pasteur (b) Oparin B. In monera the nuclear membrane is present (c) Darwin (d) Linnaeus In protista the cell type is prokaryotic 74. Classical embodies/concept of classical systematics D. In plantae the cell wall is present taxonomist is [JIPMER 1997] Of the above statements [Kerala PMT 2012] (a) Biological concepts (b) Species concept (a) A alone is correct (b) B alone is correct (c) Typological concept (c) C alone is correct (d) D alone is correct (d) All the above (e) A, B and C are correct 75. Species is [CBSE PMT 1994] 63. Cohort is a group correlated with [MHCET 2004] (a) Specific unit of evolution (a) Species (b) Genera (b) Specific unit in the evolutionary history of a race (c) Families (d) Order (c) Specific class of evolution International code of 64. "Biological nomenclature" (d) Not related to evolution applicable to 76. Two plants are taxonomically related if [NCERT] (a) Plants (b) Animals (a) They store carbohydrate in the same type of molecule (c) Both animals and plants (d) None of the above (b) Both obtain energy from hydrolysis of ATP into ADP The term "phylum" in animal classification was coined by and inorganic phosphate [CBSE PMT 1992; MP PMT 1994, 2010] (a) E. Haeckel (c) Both have similarly lobed palmate leaves (b) John Ray (c) G.L. Cuvier (d) Carolus Linnaeus (d) Both have pinnately veined leaves Family is placed between 66. [Odisha JEE 2011] A group of related genera, with still less number of 77. (a) Order and genus (b) Genus and species similarities as compared to the genus and species, (c) Class and order (d) Phylum and class constitutes [NCERT; AFMC 2009; DUMET 2010] 67. Four kingdom classification was proposed by (a) Order (b) Class [HPMT 1994; BHU 1994] (c) Family (d) Division (a) Whittaker (b) Copeland 78. Match the following and choose the correct combination (c) Haeckel (d) Linnaeus from the options given 68. Five kingdom system of classification suggested by R.H. Column I Column II Whittaker is not based on [CBSE PMT 2014] (Common name) (Taxonomic category Order) (a) Mode of nutrition (b) Complexity of body organization Wheat 1. Primata (c) Presence or absence of a well defined nucleus B. 2. Mango Diptera (d) Mode of reproduction C. 3. Housefly Sapindales 69. Cytotaxonomy is connected with [NCERT] D. Man Poales (a) Chemical composition of cytoplasm (b) Cell organelles [Kerala PMT 2010] (c) Cytochromes (a) A-1, B-2, C-4, D-3 (b) A-4, B-3, C-2, D-1 (d) Shape and size of cells (c) A-2, B-4, C-1, D-3 (d) A-3, B-4, C-2, D-1 'Taxa' differs from 'taxon' due to [DUMET 2010] (e) A-4, B-2, C-3, D-1 (a) This being a higher taxonomic category than taxon 79. In the scientific name of Mangifera indica L. (b) This being lower taxonomic category than taxon (a) Letter L. signifies latin language (c) This being the plural of taxon (d) This being the singular of taxon (b) The name is reverse with Indica preceeding mangifera The term 'biosystematics' was coined by (c) Letter L. signifies taxonomist Linnaeus [J & K CET 2010; MP PMT 2010, 12] (d) Letter L. is superfluous (a) Gaspard Bauhin (b) Camp and Gilly 80. Plant classification proposed by Carolus Linnaeus was (c) Karl Prantl (d) Robert Brown artificial because it was based on Which of the following statements regarding universal rules [NCERT; RPMT 1990; CPMT 1995] of nomenclature is wrong [Kerala PMT 2010; NEET (Phase-I) 2016] (a) Only a few morphological characters (a) The first word in a biological name represents the genus (b) Evolutionary tendencies which are diverse The first word denoting the genus starts with a capital (b) (c) Anatomical characters which are adaptive in nature letter Both the words in a biological name, when (d) Physiological traits alongwith morphological characters handwritten, are separately underlined Classification of organisms based on evolutionary as well as (d) Biological names are generally in Greek and can be genetic relationships is called [DUMET 2010] written in any language (a) Biosystematics (b) Phenetics The second component in a biological name denotes the specific epithet (c) Numerical taxonomy (d) Cladistics

UNIVE			
	DEPOT 1960	-	
82.	Carolus Linnaeus (Carl Linne) was from [Manipal 1997]	93.	Which one possess characters of both plants and animals
	(a) Sweden (b) U.K.		Or [CBSE PMT 1995]
-	(c) Holland (d) France		A unicellular organism often considered connecting link
83.	First act in taxonomy is [NCERT; Wardha 2002]		between plants and animals is [AFMC 1997; JIPMER 1998]
	(a) Description (b) Identification		(a) Bacteria (b) Mycoplasma
	(c) Naming (d) Classification		(c) Paramecium (d) Euglena
84.	Taxonomy based on determination of genetic relationships is [NCERT; JIPMER 1997]	94.	Distinction of prokaryota and eukaryota is mainly based on [NCERT; MP PMT 1995, 98]
	(a) Cytotaxonomy (b) Numerical taxonomy		(a) Nucleus only (b) Cell organelles only
0=	(c) Biochemical taxonomy (d) Experimental taxonomy		(c) Chromosomes only (d) All the above
85.	Branch connected with nomenclature, identification and classification is	95.	Algae with photosynthetic pigments possess nutrition
	[CPMT 1991; AMU (Med.) 2000; Kerala PMT 2002]	20.	[AMU (Med.) 1997; Manipal 1997]
	Or		(a) Holozoic (b) Saprophytic
	The study of theory, practice and rules of classification of		(c) Holophytic (d) Parasitic
	living and extinct organisms is called [Odisha JEE 2012]	96.	Select the incorrect statements
	(a) Ecology (b) Taxonomy	50.	(A) Lower the taxon, more are the characteristics that the
	(c) Morphology (d) Physiology		members within the taxon share
86.	Sequence of taxonomic categories is [NCERT; DPMT 1992; CBSE PMT 1992;		Order is the assemblage of genera which exhibit a few similar characters
	AFMC 1992, 2001; HPMT 1994; Pb. PMT 1997;		(C) Cat and dog are included in the same family Felidae
	KCET 2001, 11; Kerala PMT 2007; AMU (Med.) 2012]		(D) Binomial nomenclature was introduced by Carolus
	(a) Class – phylum – tribe – order – family – genus – species		Linnaeus [Kerala PMT 2011]
	(b) Division – class – family – tribe – order – genus – species		(a) A, B and C (b) B, C and D
	(c) Division – class – order – family – tribe – genus – species		(c) A and D (d) C and D
87.	(d) Phylum – order – class – tribe – family – genus – species Phylogenetic system of classification is based on		(e) B and C
07.	[NCERT; CBSE PMT 1994, 2006, 09; Pb. PMT 2000;	97.	Phylogenetic system was given
	Odisha JEE 2002; DPMT 2006]		[DPMT 2007; Kerala PMT 2009; CPMT 2010]
	(a) Evolutionary relationships		(a) Engler & Prantl (b) Pliny
	(b) Morphological features		(c) John Ray (d) R.H. Whittaker
	(c) Chemical constituents	98.	
	(d) Floral characters	20.	
88.	An attribute found in plants but not animals is		
	(a) Metabolism (b) Sexual reproduction	00	(c) Neo-taxonomy (d) Adansonian taxonomy
	(c) Autotrophy (d) Asexual reproduction	99.	Species can be identified on the basis of [MP PMT 2007]
89.	Systema Naturae was written by [CPMT 1991, 92, 93;		(a) Interbreed (b) Species diversity
	Kerala PMT 2010; Odisha JEE 2010]		(c) Reproductive isolation (d) None of these
	(a) Lamarck (b) Cuvier	100.	In the five kingdom system of classification, which single
00	(c) Aristotle (d) Linnaeus		kingdom out of the following can include blue-green algae,
90.	Which of the following taxonomist described classification of		nitrogen fixing bacteria and methanogenic archaebacteria
	plant kingdom in "Families of flowering plants" [CPMT 2004]		[NCERT; CBSE PMT 1998; Pb. PMT 1998]
	(a) Cronquist (b) Takhtajan		(a) Monera (b) Fungi
	(c) Benson (d) Hutchinson		(c) Plantae (d) Protista
91.	Mayr's biological concepts of species is mainly based on [NCERT; BVP 2004; BHU 2004, 08; CPMT 2009]	101.	Floral features are commonly used for identification of angiosperms because [NCERT; CBSE PMT 1998]
	(a) Morphological traits		(a) Reproductive parts are more conservative
	(b) Reproductive isolation		(b) Flowers can be safely pressed
	(c) Modes of reproduction		(c) Flowers are nice to work with
	(d) Morphology and reproduction		(d) Flowers have various colours and scents
92.	Two morophologically similar populations are intersterile.	102.	Two similar holotypes are called [BHU 1997]
	They belong to [NCERT; BHU 1994, 97, 2000;		(a) Mesotypes (b) Meotypes
	Kerala PMT 2005]		(c) Syntypes (d) Isotypes
	(a) One species(b) Two biospecies	103.	Binomial system of nomenclature for plants is effective from

(a) 5.8.1771

(c) 1.8.1758

(c) Two sibling species

(d) None of the above

[JIPMER 1997]

(b) 1.5.1753

(d) 6.7.1736

(d) The ancestral lineage of existing organisms

104. A system of classification that is based on evolution, order [Pb. PMT 2001] 116. Keystone species are and ancestry is known as [Pb. PMT 1998; MP PMT 1998] (a) Species belonging to same period (a) Natural system (b) Analogous system (b) Species that determine structure of biotic community (c) Phylogenetic system (d) Homologous system (c) Species reproducing sexually 105. Characteristics which delimit a family are more general than (d) Species recorded only in the fossil state those which delimit a [JIPMER 1999] 117. Nicotiana is [NCERT; Haryana PMT 2001] (a) Cohort (b) Phylum (a) Variety (b) Subspecies (c) Class (d) Genus (c) Species (d) Genus 106. First great taxonomist was [BHU 1999] 118. Barophilic prokaryotes [CBSE PMT 2005] (a) Linnaeus (b) Hooker (a) Grow slowly in highly alkaline frozon lakes at high (c) Aristotle (d) Engler altitudes 107. In the classification of plants, the term cladistics refers to the (b) Occur in water containing high concentrations of [Kerala PMT 2006: BHU 2008] barium hydroxide (a) Phylogenetic classification (b) Sexual classification (c) Grow and multiply in very deep marine sediments (c) Artificial classification (d) Natural classification (d) Readily grow and divide in sea water enriched in any (e) Binomial classification soluble salt of barium 108. Five kingdom classification includes 119. In hierarchical classification class is interpolated between [DPMT 2006] (a) Monera, Protista, Fungi, Plantae Animalia [NCERT: Chd. CET 2002] (b) Algae, Fungi, Bryophyta, Pteridophyta, Gymnosperms (a) Family and genus (b) Phylum and order (c) Virus, Prokaryota, Fungi, Plantae, Animalia (c) Order and family (d) Kingdom and phylum (d) Monera, Protista, Animalia, Plantae, Alage 120. Binomial nomenclature is [MP PMT 1997; Chd. CET 2002] 109. Which of the following is less general in characters as (a) Two words in name of a species compared to genus [NCERT; CBSE PMT 2001] (b) Two names local and specific (a) Species (b) Family (c) Two names of a species (c) Class (d) Division (d) Two phases, asexual and sexual, in the life cycle of a species 110. What is correct 121. A true species consists of a population [CBSE PMT 2002] [NCERT; Manipal 2001; Odisha JEE 2012; KCET 2012] (a) Sharing the same niche (a) Apis indica (b) trypanosoma gambiense (b) Interbreeding (c) Ficus Bengalensis (d) Mangifera indica (c) Feeding over the same food 111. Which covers the largest number of organisms (d) Reproductively isolated [Kerala PMT 2001] 122. Species are considered as [DPMT 1997; AIIMS 2000; (a) Genus (b) Family BHU 2001; Kerala PMT 2002; CBSE PMT 2003; (c) Phylum (d) Class MP PMT 2009] (a) Real units of classification devised by taxonomists (e) Order (b) Real basic units of classification 112. Which of the following is not taxon but a category The lowest units of classification [MHCET 2000] (d) Artificial concept of human mind which cannot be (a) Division (b) Angiosperms defined in absolute terms (c) Polypetalae (d) Hibiscus 123. Biosystematics aims at [CBSE PMT 2003] 113. Chemotaxonomy is connected with [NCERT; MHCET 2001] (a) Identification and arrangement of organisms on the (a) Classification of chemicals found in plants basis of their cytological characteristics (b) Use of phytochemical data in systematic botany (b) The classification of organisms based on broad (c) Application of chemicals on herbarium sheets morphological characters (d) Use of statistical methods in chemical yielding plants (c) Delimiting various taxa of organisms and establishing 114. Descending arrangements of categories is called their relationships [NCERT: MHCET 2001] (d) The classification of organisms based on their (b) Taxonomy (a) Classification evolutionary history and establishing their phylogeny on (c) Hierarchy (d) Key the totality of various parameters from all fields of study 115. Holotype is [Pb. PMT 2001] 124. Phenetic classification of organisms is based on (a) Specimen used by author as nomenclature type [NCERT; CBSE PMT 2004; WB JEE 2016] (b) Specimen referred alongwith original description (a) Dendogram based on DNA characteristics (c) Duplicate of nomenclature type (b) Sexual characteristics (d) Specimen selected from original when nomenclature (c) Observable characteristics of existing organisms

type is missing

 Match the following and select the correct combination from the options given below

Col	umn I (Kingdom)	Column II (Class)			
A.	Plantae	1.	Archaebacteria		
B.	Fungi	2.	Euglenoids		
C.	Protista	3.	Phycomycetes		
D.	Monera	4.	Algae		

[Kerala PMT 2011]

- (a) A-4, B-3, C-2, D-1
- (b) A-1, B-2, C-3, D-4
- (c) A-3, B-4, C-2, D-1
- (d) A-4, B-2, C-3, D-1
- (e) A-2, B-3, C-4, D-1
- 126. The term species was coined by [BVP 2002; KCET 2004]
 - (a) Aristotle
- (b) Engler
- (c) John Ray
- (d) Linnaeus
- 127. The common characteristics between tomato and potato will be maximum at the level of their [NEET (Karnataka) 2013]
 - (a) Family
- (b) Order
- (c) Division
- (d) Genus
- 128. The label of a herbarium sheet does not carry information on [NEET (Phase-II) 2016]
 - (a) Height of the plant
- (b) Date of collection
- (c) Name of collector
- (d) Local names

NCERT Exemplar Questions

- As we go from species to kingdom in a taxonomic hierarchy, the number of common characteristics [NCERT]
 - (a) Will decrease
- (b) Will increase
- (c) Remain same
- (d) May increase or decrease
- Which of the following 'suffixes' used for units of classification in plants indicates a taxonomic category of 'family' [NCERT]
 - (a) -Ales
- (b) -Onae
- (c) -Aceae
- (d) -Ae
- 3. The term 'systematics' refers to
- [NCERT]
- (a) Identification and classification of plants and animals
- (b) Nomenclature and identification of plants and animals
- (c) Diversity of kinds of organisms and their relationship
- (d) Different kinds of organisms and their classification
- 4. Genus represents

[NCERT]

- (a) An individual plant or animal
- (b) A collection of plants or animals
- (c) Group of closely related species of plants or animals
- (d) None of these
- The taxonomic unit 'Phylum' in the classification of animals is equivalent to which hierarchial level in classification of plants

NCERTI

- (a) Class
- (b) Order
- (c) Division
- (d) Family

- 6. Botanical gardens and zoological parks have
 - (a) Collection of endemic living species only
 - (b) Collection of exotic living species only
 - (c) Collection of endemic and exotic living species
 - (d) Collection of only local plants and animals
- 7. Taxonomic key is one of the taxonomic tools in the identification and classification of plants and animals. It is used in the preparation of [NCERT]
 - (a) Monographs
- (b) Flora
- (c) Both (a) and (b)
- (d) None of these
- 8. All living organisms are linked to one another because

[NCERT]

[NCERT]

- (a) They have common genetic material of the same type
- (b) They share common genetic material but to varying degrees
- (c) All have common cellular organization
- (d) All of above
- Which of the following is a defining characteristic of living organisms [NCERT]
 - (a) Growth
- (b) Ability to make sound
- (c) Reproduction
- (d) Response to external stimuli
- 10. Match the following and choose the correct option [NCERT]
 - Family
 - B. Kingdom
- ii. Polymoniales

tuberosum

v-A

v-C

v-C

Objective Questions

- C. Order
- iii. Solanum
- D. Species E. Genus
- v. Solanacea

- (a) i-D,
- ii-C,
- iv-B, iv-A,
- (b) i-E, ii-D, (c) i-D. ii-E.
 - ii-E, iii-B,
- iv-A.

- (d) i-E,
- ii-C,
- iii-B,

iii-E,

iii-B.

iv-A, v-D

Critical Thinking

- Karyotaxonomy is the modern branch of classification which is based on [NCERT; JIPMER 1998; MP PMT 1999]
 - (a) Number of chromosomes
 - (b) Bands found on chromosomes
 - (c) Organic evolution
 - (d) Trinomial nomenclature
- 2. Which of the following combinations is correct for wheat

[DUMET 2010]

- (a) Genus: Triticum, Family: Anacardiaceae,
 - Order : Poales, Class : Monocotyledonae
- (b) Genus: Triticum, Family: Poaceae,
 - Order : Poales, Class : Dicotyledonae
- (c) Genus: Triticum, Family: Poaceae.
 - Order : Sapinadales, Class : Monocotyledonae
- (d) Genus: Triticum, Family: Poaceae,
 - Order : Poales, Class : Monocotyledonae

UNIVERSAL BOOK DEPOT 1960

3. Hutchinson's system of classification was revised in

[DPMT 2003]

- (a) 1995
- (b) 1959
- (c) 1954
- (d) 1946
- The total number of species included in the animal kingdom are about [CBSE PMT 1992; DUMET 2010]
 - (a) 1 million
- (b) 2 million
- (c) 10 million
- (d) 1 billion
- Which one of the taxonomic aids can give comprehensive account of complete compiled information of any one genus or family at a particular time [NCERT; Kerala PMT 2009]
 - (a) Taxonomic key
- (b) Flora
- (c) Herbarium
- (d) Monograph
- (e) Dictionary
- 6. A species is defined as "the group of actually or potentially inter-breeding natural population producing fertile offspring and reproductively isolated from such other groups". The above statement is given by [MP PMT 1997]
 - (a) Carolus Linnaeus
- (b) Mayr
- (c) J.B. lamarck
- (d) Charles Darwin
- Which of the following is required as equivalent to subspecies of classical Taxonomy [VITEEE 2006]
 - (a) Ecospecies
- (b) Ecotype
- (c) Cenospecies
- (d) Comparium
- Which one of the following statement correctly define the term homonym [WB JEE 2008]
 - (a) Identical name of two different taxon
 - (b) Two or more names belonging to the same taxon
 - (c) When species name repeats the generic name
 - (d) Other name of a taxon given in a language other than the language of zoological / botanical nomenclature

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : Phylogeny is the developmental history of a species.
 - Reason : Species is the basic unit of taxonomy.
- Assertion : Whittaker's classification for algae is not acceptable.
 - Reason : Whittaker grouped algae in different kingdoms.

- Assertion : Chemotaxonomy is classifying organisms at molecular level.
 - Reason : Cytotaxonomy is classifying organisms at cellular level.
 - Assertion : Whittaker did not include unicellular green
- algae in protista.

 Reason : Distinction between unicellular and
 - multicellular organisms is not possible in case of algae.
- Assertion : Systematics is the branch of biology that deals with classification of living organisms.
 - Reason : The aim of classification is to group the organisms. [AIIMS 2002]
- **6.** Assertion : Acraniata is a group of organisms which do not have distinct cranium.
 - Reason : It includes small marine forms without head. [AIIMS 1997]
- 7. Assertion : To give scientific name to plant, there is ICBN.
 - Reason : It uses articles, photographs and recommendations to name a plant.

[Haryana PMT 2000]

- **8.** Assertion : Taxon and category are same things.
 - Reason : Category shows hierarchical classification.
- **9.** Assertion : The hierarchy includes seven obligate categories.
 - Reason : Intermediate categories are used to make taxonomic positions more informative.
- **10.** Assertion : The species is reproductively isolated natural population.
 - Reason : Prokaryotes cannot be kept under different species on the basis of reproductive isolation.
- 11. Assertion : Bacteria, Protista do not have circulatory
- Reason : These organisms live in moist and watery environment. [AIIMS 2010]
- 12. Assertion : Living organisms possess specific individuality with the definite shape and
 - Reason : Both living and non living entities resemble each other at the lower level of organization. [AIIMS 1999]

S Answers and Solutions

Nature and Scope of Biology

- 5. (d) Edaphology is study of soil.
- 11. (b) Pharmacology is the branch of medicine and biology concerned with the study of drug action, where a drug can be broadly defined as any man made, natural or endogenous (with in the body) molecule which exerts a biochemical and/or physiological effect on the cell, tissue, organ or organism.
- (c) Phenology is the scientific study of seasonal changes, i.e., periodic phenomena of organisms in relation to their climate.

Understanding Life

- (a) In endergonic reactions, the product have more energy than the reactants, So the reaction requires an input of energy.
- (b) Iron is component of haemoglobin of RBC of blood and helps in transportation of oxygen (about 97-99%) as well as carbon dioxide (about 23%).
- (a) Submicroscopic particles such as Glucose amino acid, Nucleotides etc.
- 18. (a) Xerophytic plant of deserts, has a number of adaptation to reduce transpiration for water conservation e.g. stem is covered by thick cuticle and has high succulency while leaves are modified into spines.
- 20. (b) Water is the most abundant substance of living beings. In adult human body 20-22 litres (50% of the total) is present inside the cells as intracellular water.
- 22. (d) The shape, size, structure and biological functions of proteins are determined by the number type and arrangement of aminoacids.
- 24. (d) Animal imitate other animals, plants and natural objects in order to protect themselves from predators, called protective mimicry. Predatory animals mimic some natural object so that their prey get confused and is easily attacked or caught. This type of mimicry is called Agressive mimicry.

- 27. (b) Starch common in plant and glycogen in animals are two food storage polysaccharides. Both of them can easily be hydrolysed into their glucose monomers.
- 29. (c) Reproduction capacity found only in living being.
- 31. (b) Flourescence is the process in which excess energy is lost by light waves. Because of this energy loss, the wavelength of the light energy released in flourescence is generally longer than that of originally absorbed.
- 32. (a) Maximum energy is provided by fats (9.45 K. cal).
- 34. (a) A living system which can exchange the matter and energy with the environment is called an open system.

Systematics

- (c) Nomenclature (Nomen = name; clature = to call) is giving distinct scientific names to various structures, including living organisms, so they can be easily identified.
- 4. (a) Taxonomy based on all available information and attempting to classify organisms, according to their origin, evolution and variation is called classical taxonomy. A taxonomist engaged in studying origin, evolution, variations and classification of organisms is called classical taxonomist.
- (d) Original specimen is called holotype and the duplicate of holotype is termed as isotype.
- 8. (a) The closely related orders are grouped into a class (named as a taxonomical rank in classification) which have least similar organisms to another.
- (a) Family is a taxonomic category between the division and order. It includes one or more genera. Its suffix is 'aceae'.
- 15. (d) In botanical nomenclature of plants generic name always begin with capital letter and the specific name with a small letter and printed in italics.
- 18. (c) In the natural system of classification organisms are arranged according to their natural affinities through the use of all important characters. Characteristics such as structural, cytological, reproductive and biochemical are included. The characters are useful in bringing out homology.
- 20. (c) The 'Binomial system of nomenclature' was explained by Carl Linnaeus in his book 'species plantarum' in 1753. According to this system name of any organism/plant consist of two words. First represents its 'genera' and second its 'species'.
- 24. (a) Linnaeus system of classification is considered as artificial because it is based only on one or two character of plants.
- 31. (c) In five kingdom classification of Whittaker eukaryotes were assigned to only four of the five kingdom. Prokaryotes are included in kingdom monera.
- **35.** (d) Gymnosperms and angiosperms both are grouped under phanerogams because both are bearing seeds.
- (b) Angiosperms flowering plants constitute the dominating terrestrial flora of the world is known as spermatophyta.

- 44. (b) Monera contains the most primitive living forms which are basically unicellular prokaryotes.
- 47. (d) The term new systematics was proposed by Sir Julian Huxley in 1940. In the new systmatics, the species are considered related to one another mutable and the work of gradual modification. This is in conformity with the facts of evolution.
- 49. (c) Sometimes organisms of same species differ from each other as they are adapted for different kinds of environment. In such cases species are again divided into subspecies.
- **50.** (b) Carolus Linnaeus introduced binomial nomenclature in his tenth edition of 'Systema naturae'.
- (d) R.H. Whittaker (1969), an American ecologist, divide all the organisms into five kingdoms.
- **59.** (b) An individual of a species can interbreed to produce fertile offspring.
- 60. (c) Natural system of classification is based on the large number of morphological characters and natural affinities of organism.
- (b) Plasmodium falciparum A protozoan pathogen causes the most serious type of malaria that is falciparum malaria.
- 67. (b) Four kingdom (Plantae, animalia, protista and monera) classification was developed by Copeland (1956). The main drawback of this system is that fungi are not properly placed.
- 68. (c) The main criteria of Whittaker's system are :- Cell type, Thallus organization, Nutrition, Reproduction and Phylogenetic relationship.
- 69. (b) Cytotaxonomy based on information about cytological structure, chromosomes numbers, structure and behaviour during meiosis and cell organelles.
- **83.** (b) Identification is assigning an organism its correct name and placing it in its proper taxonomic category.
- **84.** (d) Experimental taxonomy based on the experimental determination of the genetic relationship, environmental impact and evolutionary divergence within a group.
- 85. (b) Taxonomy is a branch of biology which deals with the study of principles and procedures of classification, nomenclature and identification. The term taxonomy was coined by De Candolle (1813).
- 87. (a) In phylogenetic system, the organisms are classified according to their evolution of genetic affinities. The system of classification proposed by Engler (1886) by Hutchinson (1926) and by Tippo (1942) are phylogenetic.
- 88. (c) Autotrophy is a characteristics of plants.
- 89. (d) In 1735, Carolus Linnaeus published the first edition of his classification of living things in his Systema Naturae.
- 90. (d) John Hutchinson put forward a classification on phylogenetic lines in the book "families of flowering plants".

- 91. (b) Mayr defined species as group of interbreeding natural population that are reproductively isolated from each other group.
- **92.** (c) Sibling species: True species which do not interbreed but are otherwise difficult to separate on the basis of morphological characters alone.
- **95.** (c) Algae with photosynthetic pigment possess photosynthetic (holophytic) nutrition.
- **110.** (d) Because *Mangifera indica* is a correct representation of scientific name. According to binomial nomenclature.
- 111. (c) Phylum includes one or more related classes. All the classes of a phylum possess some common correlated traits. So the phylum covers the largest numbers of organism.
- 126. (c) Term species was coined by John Ray in 1693.
- 128. (a) The herbarium sheets carry a label providing information about date and place of collection, english, local and botanical names, family, collector's name

Critical Thinking Questions

- (b) Karyotaxonomy is based up on nucleus and band on chromosomes.
- (a) Hutchinson's systems of classification (1884-1972) are the best known phylogenetic system. It was revised in 1995.
- (a) Currently 1.7 million living organisms are known to science. Out of these 1.2 million are animals and about 0.5 million plants.

Assertion and Reason

- 1. (b) Phylogeny is the developmental history of a species or a group of species. Species is the basic unit of taxonomy. It is a natural population of individuals or group of population which resemble one another in all essential morphological and reproductive characters so that they are able to interbreed freely and produce fertile offspring.
- 2. (a) In Whittaker's classification, algae are grouped in three kingdoms Monera (blue-green algae), Protista (dinoflagellates, diatoms, euglenoids) and Plantae (red algae, brown algae and green algae). Though plant kingdom of Whittaker is often called metaphyta or multicellular plants, the algae included in this kingdom also contain a number of unicellular and colonial forms. The most accepted classification of algae is given by Fritsch. He classified all algae into 11 classes.
- 3. (b) All the members of a species have similar karyotype (cytotaxonomy) – there is similarity in the number, size, shape and behaviour of chromosomes. At the molecular level there is similarity in the types of proteins, enzymes, hormones and other biochemicals.

- 4. (a) A distinction between unicellular and multicellular organisms is not possible in case of algae in Whittaker's system. It is because of this that unicellular green algae have not been included in kingdom protista.
- (b) Systematics is related with classification of organisms. In classification the organisms are grouped on the basis of their characters or phylogeny, etc.
- (b) Acraniata includes marine forms without head or cranium. They lack jaws, vertebral column, paired appendages.
- 7. (a) Anyone can study, describe, identify and give a name to an organism provide certain rules are followed. These rules are formed and standardised by International Code of Botanical Nomenclature (ICBN). It uses articles, photographs and recommendations.
- 8. (e) A category is a rank or level in the hierarchial classification of organisms. Taxon is a unit in classification which may represent any level of grouping of organisms based on certain common characteristics. There is some confusion in the use of taxon and category, for example Bryophyta is a taxon while division is a category.
- 9. (b) The hierarchy includes seven obligate categories kingdom, division or phylum, class, order, family, genus and species. In order to make taxonomic position of species more precise, certain categories have been added to this list. They are called intermediate categories, e.g., subkingdom, superphylum or superdivision, superclass, subclass, superorder, suborder, superfamily, subfamily, tribe, subspecies, variety etc.
- 10. (b) The species is genetically distinct and reproductively isolated natural population. Sexual reproduction is absent in prokaryotes and some protists. In such cases morphological differences, cytotaxonomy and chemotaxonomy are resorted to.
- 11. (b) Bacteria, Protista are single-celled organisms. They do not have circulatory systems and live in moist and watery environments so that all their cells are close enough to the external environments for the direct exchange of substances such as water and gases.
- 12. (b) All living organisms have definite shape and size and all show specific individuality with a orderly mannered organization whereas at the lower level of organization, both the living and non living made up of atoms.

ET Self Evaluation Test

 When generic name is repeated in specific name of a plant it is called [NCERT]

Or

In fish, Catla catla the specific name is identical with the generic name, thus it is an example of

[AMU (Med.) 2012; WB-JEE 2016]

- (a) Synonyms
- (b) Antonyms
- (c) Tautonyms
- (d) None of the above
- 2. Specimen used for original publication by the author is

[AIIMS 1996]

- (a) Holotype
- (b) Isotype
- (c) Syntype
- (d) Lactotype
- Number of criteria used in classifying organisms in fivekingdom classification is [NCERT; MP PMT 2001]
 - (a) 5

(b) 4

(c) 3

- (d) 2
- 4. Artifical system of classification was first used by
 - (a) Linnaeus
- (b) De Candolle
- (c) Theophrastus
- (d) Bentham and Hooker
- 5. Archegoniatae include
 - (a) Algae, fungi and viruses
 - (b) Algae, lichens and bryophytes
 - (c) Bryophytes, pteridophytes and gymnosperms
 - (d) Pteridophytes, gymnosperms and angiosperms
- 6. Institution which encourages publication of local flora is

[APMEE 2001]

- (a) NBRI
- (b) FRI
- (c) BSI
- (d) IARI
- "Taxonomy without phylogeny is similar to bones without flesh" is the statement of
 - (a) Oswald Tippo
- (b) John Hutchinson
- (c) Takhtajan
- (d) Bentham and Hooker
- The scientist who created the group Protista for both unicellular plants and animals is
 - (a) Haeckel
- (b) Pasteur
- (c) Lister
- (d) Koch
- 9. In a scientific name, the name of author is printed in
 - (a) Italics
- (b) Bold (antics)
- (c) Roman
- (d) Capital letters

10. The generic name of Mango is

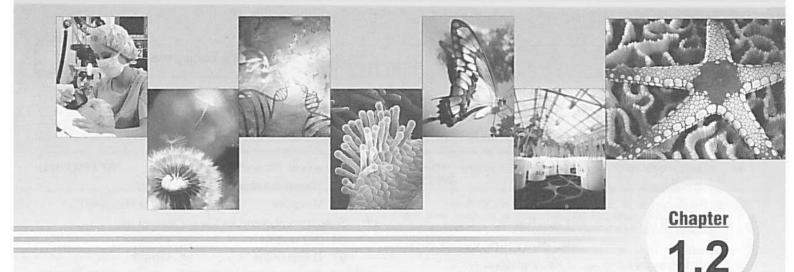

[MP PMT 2011]

- (a) Mangifera indica
- (b) Indica
- (c) Mangifera
- (d) Indica Mangifera
- 11. Static concept of species was put forward by
 - (a) De Candolle
- (b) Linnaeus
- (c) Theophrastus
- (d) Darwin

Answers and Solutions

1	C	2	a	3	a	4	C	5	C
6	С	7	C	8	a	9	С	10	C
11	b								

- (c) If both generic and specific names are same, these are called tautonyms.
- (a) Holotype is a original type specimen from which the description of a species is established.
- 3. (a) The main criteria for classifying organisms into five kingdoms are complexity of cell structure, body organisation, the mode of nutrition, life style and the phylogenetic relationships.
- (c) Artificial system of classification was first used by Theophrastus. A classification based on one or a few superficial similarities is called an artificial system of classification.
- (c) Archegoniatae is a group of embryophytes having archegonia. Its include bryophytes, pteridophytes and gymnosperm.
- (c) Botanical Survey of India at Kolkata explores the plant wealth of India.
- (a) A German biologist Ernst Haeckel created a third kingdom protista in 1866 for unicellular organism such as bacteria, protozoans, algae and fungi.
- (c) In a scientific name, the name of author is printed in Roman. e.g., Mangifera indica linn, the linn. stand for Linnaeus.
- (b) The static concept of species was given by Linnaeus in systema naturae.

Monera (Prokaryotes)

Characteristics of Monera

Monera (Monos - single) includes prokaryotes and shows the following characters:

- (1) They are typically unicellular organisms (but one group is mycelial).
- (2) The genetic material is naked circular DNA, not enclosed by nuclear envelope.
- (3) Ribosomes and simple chromatophores are the only subcellular organelles in the cytoplasm. The ribosomes are 70 S. Mitochondria, plastids, golgi apparatus, lysosomes, endoplasmic reticulum, centrosome, etc., are lacking.
- (4) Sap vacuoles do not occur. Instead, gas vacuole may be present.
- (5) The predominant mode of nutrition is absorptive but some groups are photosynthetic (holophytic) and chemosynthetic.
- (6) The organisms are non-motile or move by beating of simple flagella or by gliding.
- (7) Flagella, if present, are composed of many intertwined chains of a protein **flagellin**. They are not enclosed by any membrane and grow at the tip.
 - (8) Moneran cells are microscopic (1 to few microns in length).
 - (9) Most organisms bear a rigid cell wall (Peptidoglycan).
- (10) Reproduction is primarily asexual by binary fission or budding. Mitotic apparatus is not formed during cell division.
- (11) The kingdom Monera includes true bacteria, mycoplasma, rickettsias, actinomycetes (ray fungi) etc. Microbiologists also include blue green algae (i.e., Cyanobacteria) under the group of bacteria because of the presence of prokaryotic cell structure. Studies have established that the members of archaebacteria group are the most primitive and have separated from eubacteria group very early in the process of evolution.

Bacteria

Study of bacteria is called bacteriology. Linnaeus placed them under genus vermes. Nageli classified bacteria under schizomycetes. Bacteria are unicellular, microscopic and cosmopolitan organisms. The branch of science, which deals with the study of microorganism and their process is called as microbiology. Antony Van Leeuwenhoek is known as father of bacteriology and father of modern microbiology is Robert Koch.

These are the smallest cell wall having prokaryotic cell. The bacteria constitute a highly specialised group of one celled plants. They differ from animals in having a rigid cell wall and being capable to synthesize vitamins. Bacteria were first seen by a Dutch lens maker, Antony Van Leeuwenhoek (1683) who named them animalcules. Louis Pasteur (1822-95) made a detailed study of bacteria and proposed germ theory of disease. Ehrenberg (1829) was the first to use the term bacterium. Robert Koch (1881) found that some diseases like tuberculosis, cholera in man, and anthrax in cattle is caused by bacteria. Lister introduced antiseptic surgery. He used carbolic acid for sterilization of surgical instrument. Pasteurization theory was proposed by Louis Pasteur.

- (1) **Size :** They are 3 to 5 microns ($1\mu = 1/1000$ millimetre or about 1/25,000 inch) in length. A few species of bacteria are approximately 15μ in diameter.
- \square Smallest known bacterium is *Dialister pneumonsintes* (0.15–0.3 μ).
- ☐ Largest known bacterium is a recently discovered bacterium thiomargarita namibiensis (earlier Bacillus buschili in cockroach and Spirillum volutans were considered to be the largest bacteria).

(2) Shape: The bacteria possess the following forms:

Cocci (Gk. Kokkos = Berry): They are oval or spherical in shape. They are called micrococcus when occur singly as in Micrococcus, diplococcus when found in pairs as in Diplococcus pneumoniae, tetracoccus in fours, streptococcus when found in chains as in Streptococcus lactis, staphylococcus when occurring in grape like clusters as in Staphylococcus aureus and Sarcine, when found in cubical packets of 8 or 64 as in Sarcina.

Bacilli : They are rod-shaped bacteria with or without flagella. They may occur singly (bacillus), in pairs (diplobacillus) or in chain (*streptobacillus*).

Vibrios: These are small and 'comma or kidney' like. They have a flagellum at one end and are motile, vibrio bacteria has curve in its cell e.g., Vibrio cholerae.

Spirillum (Spira = Coil) : They are spiral or coiled like a cork-screw. The spirillar forms are usually rigid and bear two or more flagella at one or both the ends e.g., Spirillum, Spirochaetes etc.

Filament : The body of bacterium is filamentous like a fungal mycelia. The filaments are very small *e.g.*, *Beggiota*, *Thiothrix* etc.

Stalked: The body of bacterium possesses a stalk e.g., Caulobacter.

Budded: The body of bacterium is swollen at places e.g., Rhodomicrobium.

(3) **Flagellation**: Depending upon the presence or absence of flagella, the bacteria are of following types:

Atrichous : When the flagellum is absent it is called atrichous. e.g., Pasteurella pestis, Lactobacillus.

Monotrichous : Only one flagellum is found at one end. e.g., Vibrio cholerae.

Lophotrichous: When a group of flagella is present at one end e.g., Spirillum volutans.

Amphitrichous : When single or group of flagella is present at both the end e.g., *Nitrosomonas*.

Peritrichous: A number of flagella are present all over the body. e.g., E. coli, Clostridium tetani.

Staining of bacteria

- Simple staining: The coloration of bacteria by applying a single solution of stain to a fixed smear is termed simple staining. The cells usually stain uniformly.
- (2) Gram staining: This technique was introduced by Hans Christian Gram in 1884. It is a specific technique which is used to classify bacteria into two groups Gram +ve and Gram -ve. The bacteria are stained with weakly alkaline solution of crystal violet. The stained slide of bacteria is then treated with 0.5 percent iodine

solution. This is followed by washing with water or acetone or 95% ethyl alcohol. The bacteria which retain the purple stain are called as Gram +ve. Those which become decolourised are called as Gram -ve. In general the wall of Gram +ve bacteria have simpler nature as compared to Gram -ve bacteria. *E.coli* is a Gram -ve bacterium. Gram negative bacterium can be seen with other stain safranin.

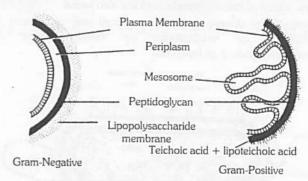

Fig: 1.2-1 Difference between cell walls of Gram-negative and Gram- positive bacteria

Gram positive bacteria: e.g., Pneumococcus, Streptococcus, Staphylococcus, Bacillus, Clostridium, Mycobacterium, Streptomyces.

Gram negative bacteria : e.g., Salmonella, Pseudomonas, Escherichia, Haemophilus, Helicobacter, Vibrio, Rhizobium.

Table: 1.2-1

Gram + Positive	Gram - Negative
Cell wall thick (250 - 300 Å).	Cell wall thin (100 – 150 Å)
Cell wall homogenous.	Cell wall heterogenous.
Cell wall single layered.	Cell wall 3-layered.
Cell wall more rigid.	Cell wall less rigid
Cell wall made up of mucopeptide (80%).	Cell wall made up of lipoprotein, mucopeptide and lipopolysaccharide.
Teichoic acid (5 – 10%) present.	Teichoic acid absent.
Spore producing forms included.	No spore producing form.
Polar flagellum usually absent.	Polar flagellum usually present.
Contain Mg-ribonucleate.	Mg-ribonucleate absent.
May produce exotoxins.	May produce endotoxins.
Sensitive to penicillin.	Not sensitive to penicillin.
L-lysin present in peptide	Diamino palmilic acid present in peptide.
O-antigen absent	O-antigen present

Structure of bacteria

(1) Capsule: In a large number of bacteria, a slimy capsule is present outside the cell wall. It is composed of polysaccharides and the nitrogenous substances (amino acids) are also present in addition. This slime layer becomes thick, called capsule. The bacteria, which form a capsule, are called capsulated or virulent bacteria. The capsule is usually found in parasitic forms e.g., Bacillus anthracis, Diplococcus pneumoniae, Mycobacterium tuberculosis.

28 Monera (Prokaryotes)

(2) Cell wall: All bacterial cells are covered by a strong, rigid cell wall. Therefore, they are classified under plants. Inner to the capsule cell wall is present. It is made up of polysaccharides, proteins and lipids.

In the cell wall of bacteria there are two important sugar derivatives are found i.e., NAG and NAM (N-acetyl glucosamine and N-acetyl muramic acid) and besides L or D - alanine, D-glutamic acid and diaminopimelic acid are also found.

One of the unique components of cell wall of bacteria is peptidoglycan or mucopeptide or murein (made of mucopolysaccharide + polypeptide).

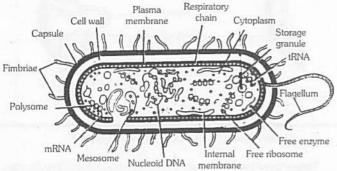

Fig: 1.2-2 Electron microscope structure of a bacterium cell

(3) Plasma membrane: Each bacterial cell has plasma membrane situated just internal to the cell wall. It is a thin, elastic and differentially or selectively permeable membrane. It is composed of large amounts of phospholipids, proteins and some amounts of polysaccharides but lacks sterols. It is characterised by possessing respiratory enzymes.

Mesosome: On the plasma membrane generally at mid point, there are present some circular coiled bodies called mesosomes. So mesosomes are simply infoldings of plasma membrane. Mesosomes contain respiratory enzymes like oxidases and dehydrogenases and hence they help in respiration. Hence mesosomes are also known as "mitochondria of bacterial cell" or chondrioides. Mesosomes are more prominent in Gram +ve bacteria.

- □ It receive DNA during conjugation and DNA replication enzyme.
- Mesosome participate in the formation of septa during cell division.
- (4) Cytoplasm and Cytoplasmic inclusions: The cytoplasm is a complex aqueous fluid or semifluid ground substance (matrix) consisting of carbohydrates, soluble proteins, enzymes, coenzymes, vitamins, lipids, mineral salts and nucleic acids. The organic matter is in the colloidal state.

The cytoplasm is granular due to presence of a large number of ribosomes. Ribosomes (70S) in bacteria are found in the form of polyribosome. Membranous organelles such as mitochondria, endoplasmic reticulum, golgi bodies, lysosomes and vacuoles are absent.

Volutin granules : They were first reported in *Spirillum volutans* bacteria. These are also known as metachromatic granules, which are composed of polyphosphate. Volutin serves as a reserve source of phosphate.

Poly-β-hydroxy butyric acid granules (PHB): These are polymer of lipid like material and chloroform soluble which are often found in aerobic bacteria especially under high carbon low nitrogen culture conditions. Granules can serve as a reserve carbon and energy source.

Glycogen and Sulphur granules : Glycogen are also known as polysaccharide granules. It can be stained brown with iodine. By electron microscopy they appear as dark granules.

- (5) **Nucleoid**: It is also known as genophore, naked nucleus, incipient nucleus. There is present nuclear material DNA which is double helical and circular. It is surrounded by some typical protein (polyamine) but not histone proteins.
- (6) **Plasmid**: In addition to the normal DNA chromosomes many bacteria (e.g., E.coli) have extra chromosomal genetic elements or DNA. These elements are called plasmids. Plasmids are small circular double stranded DNA molecules. The plasmid DNA replicates independently maintains independent identity and may carry some important genes. Plasmid term was given by Lederberg (1952). Some plasmids are integrating into the bacterial DNA chromosome called episomes.

Types of plasmid

- (i) F-factor or Fertility factor: Which is responsible for transfer of genetic material.
- (ii) **R-factor or resistance factor :** It provides resistance against drugs.
- (iii) Colicinogenic factor: Which produces 'Colicines' which kill other bacteria (other than which produce these colicines).
- (7) **Flagella**: These are fine, thread-like, protoplasmic appendages which extend through the cell wall and the slime layer of the flagellated bacterial cells. These help in bacteria to swim about in the liquid medium.

The diameter of each subunit is about 40-50Å. These subunits are arranged around a hollow axis. A flagellum is usually 4.5μ long and 120-185Å in diameter. Flagellum is attached to cell membrane by a special terminal hook, which is attached to the basal body called (blepharoplast). A bacterial flagellum can be divided into three parts – (Basal granule, Hook and Filament).

(8) **Pili or Fimbriae**: Besides flagella, some tiny or small hairlike outgrowths are present on bacterial cell surface. These are called pili and are made up of pilin protein. They measure about $0.5-2\mu m$ in length and $3-5\mu m$ in diameter. These are of 8 types I, II, III, IV, V, VI, VII, and F types. I to F are called sex pili. These are present all most all gram –ve bacteria and few gram +ve bacteria. Fimbriae take part in attachment like holding the bacteria to solid surfaces.

Reproduction in bacteria

Vegetative reproduction

- (1) **By budding**: According to Bisset and Hale, reproduction by budding takes place in Bigidi bacterium bifidus.
- (2) By binary fission: This type of reproduction is most common in all kinds of bacteria. Under favourable conditions bacterial cell expands. Cytoplasm divides into two parts due to constriction and formation of a transverse septum in the centre of the cell. Later on, these two parts separate from each other and give rise to two cells.

Asexual reproduction

(1) **By endospores :** Endospores are formed in all species of the genera *Bacillus* and *Clostridium*. In each cell only one endospore is formed. Endospore is highly resistant to very high and very low temperature.

Endospore is found either in the centre or near the cell wall. Under unfavourable conditions cytoplasm shrinks and gets rounded and around it a hard protective three layer is formed. Each endospore may be either circular, ellipsoidal or semicircular. When favourable conditions come, outer layers rupture and active bacterial cell comes out. So this is a method of perennation (i.e., to tide over unfavourable condition) and some people say it "reproduction without multiplication".

- (2) **By conidia :** Some filamentous bacteria *e.g.*, *Streptomyces* reproduce by means of conidia. The conidia are spore like in structure and are formed in chains. Each conidium gives rise to a new bacterium.
- (3) By zoospores: In rare cases bacterial cell forms some motile spores which give rise to new cells. This process has been rarely seen. e.g., Rhizobium.

Sexual reproduction (Genetic recombination)

Sometimes it was believed that sexual reproduction does not take place in bacteria. *Lederberg* and *Tatum* (1946) proved that sexual reproduction takes place in bacteria. On the basis of this discovery they were awarded Nobel Prize.

According to the present view, three types of sexual reproduction are found in bacteria :

- (1) **Transformation:** In this process one kind of bacterium is transformed into another kind. It takes place by transferring DNA from capsulated to non-capsulated bacterium. For the first time *Griffith* (1928) reported transformation in mice. Later on, *Avery, McLeod* and *McCarty* (1944) studied transformation in *Diplococcus pneumoniae*.
- (2) **Transduction:** In this process DNA of a bacterial cell is transferred into another bacterial cell through bacteriophage a kind of virus which is parasitic upon bacteria. Bacteriophage consists of DNA. It has been now accepted that DNA of a bacterial cell is transferred through bacteriophage to another bacterium. Transduction was first of all reported by *N.D. Zinder* and *Lederberg* (1952) in bacteria *Salmonella typhimurium*.
- (3) **Conjugation :** In this process genetic material from one strain of bacterium which is known as *male* is transferred into another strain of bacterium which is known as *female*. On the experimental basis it is believed that genetic material of male enters into female bacterium in the form of a straight line. *Lederberg* and *Tatum* first of all reported conjugation in bact.0erial strain of *E.coli* called K_{12} (1946). In 1966, *Wollman* and *Jacob* described it in details.

In gram negative bacteria, there are two strains, F⁺ (with fertility factor and sex pili) and F⁻ (without fertility factor and sex pili). These two can come together. Sex pilus of donor cell extrudes a protein that helps it in attaching to the recipient cell. Latter on, sex pilus is converted into conjugation tube between the two. The donor or F⁺ can transfer its fertility factor or plasmid to recipient cell or F⁻ and convert it into donor as well. Sometimes the F⁺ plasmid attaches to nucleoid, becomes episome and converts the

donor into HFr (high frequency of recombination 1:100). There is a transfer of few genes of nucleoid from HFr to F^- . HFr quality can also be transferred occasionally (HFr \times F^- = F^- plus a few genes and a few HFr). The transferred segment is called **exogenote** which 'similar' segment of the recipient bacterium is known as **endogenote**. The recipient bacterium is called **merozygote** or **partial zygote**. Some of the donor genes integrate into recipient genome.

In gram positive bacteria sex pili do not develop. Donor cells produce a protein adhesion over their surface for bringing recipient cells in contact with them. In Streptococcus faecalis, the recipient cells excrete a small peptide (sex hormone) for inducing clumping. Wall dissolves in the region of contact. Transfer of DNA segment occurs from donor to recipient cell.

Respiration in bacteria

With respect to oxygen requirement and mode of cellular respiration, bacteria distinctly belong to two broad categories :

(1) Aerobic respiration

Obligate aerobes : These bacteria grow exclusively in presence of molecular oxygen and fail to survive in its absence, e.g., Bacillus subtilis, Azotobactor, Arthrobactor, Mycobacterium etc.

Facultative anaerobes : The aerobic bacteria which can also survive in absence of oxygen, *e.g.*, *Aerobacter*, *Klebsiella*, *Pseudomonas*, etc.

(2) Anaerobic respiration

Obligate anaerobes: These bacteria grow and multiply in the absence of free oxygen. They fail to survive under aerobic conditions, e.g., Clostridium botulinum.

Facultative aerobes : The anaerobic bacteria which can also survive in presence of oxygen, e.g., Chlorobium limicola.

Mode of nutrition in bacteria

On the basis of mode of nutrition, bacteria are grouped into two broad categories. First is autotrophic and second is heterotrophic bacteria.

Autotrophic bacteria : These bacteria are able to synthesize their own food from inorganic substances, as green plants do. Their carbon is derived from carbon dioxide. These are divided into two categories.

(1) Photoautotrophic bacteria: These bacteria are mostly anaerobic bacteria. They use sunlight as source of energy to synthesize food.

They possess a pigment called bacteriochlorophyll which is different from the chlorophyll pigment found in higher plants. This is known as anoxygenic photosynthesis. e.g., **Green sulphur** (*Thiothrix*) and **purple sulphur** (*Chromatium*) bacteria.

Green sulphur bacteria: They are autotrophic. The hydrogen donor is H_2S and the pigment involved in the process is **chlorobium chlorophyll** (Bacterioviridin) *e.g.*, *Chlorobium*.

$$6CO_2 + 12H_2S \xrightarrow[\text{Chlorobium chlorophyll}]{} C_6H_{12}O_6 + 6H_2O + 12S \; .$$

Purple sulphur bacteria : They are also autotrophic. The hydrogen donor is thiosulphate and the pigment involved in photosynthesis is **bacteriochlorophyll** *e.g.*, *Chromatium*.

$$\begin{array}{c} 6CO_2 + 15H_2O + 3Na_2S_2O_3 \xrightarrow[\text{Bacteriochlorophyll}]{} \\ C_6H_{12}O_6 + 6H_2O + 6NaHSO_4 \; . \end{array}$$

30 Monera (Prokaryotes)

Purple non-sulphur bacteria : They are heterotrophic utilizing succinate or malate or alcohol. *e.g.*, *Rhodospirillum*, *Rhodopseudomonas*.

$$6CO_2 + 12CH_3CHOHCH_3 \longrightarrow$$

$$C_6H_{12}O_6 + 12CH_3COCH_3 + 6H_2O$$
.

(2) Chemoautotrophic bacteria: Some bacteria manufacture organic matter from inorganic raw materials (such as carbon dioxide) and utilize energy liberated by oxidation of inorganic substances present in the external medium such as ammonia, ferrous ion, nitrates, nitrites, molecular hydrogen, etc.

Sulphur bacteria : These bacteria derive energy by oxidizing hydrogen sulphide or molecular sulphur. *Beggiatoa*, a colourless sulphur bacterium oxidises hydrogen sulphide (H_2S) to water and sulphur. The energy released is used up and the sulphur granules are deposited inside or outside the body of bacterial cell.

$$2H_2S + O_2 \longrightarrow 2H_2O + 2S + \text{Energy}$$
.

Iron bacteria : They take energy from the oxidation of ferrous salts into ferric salts e.g., Ferrobacillus, Leptothrix.

$$4FeCO_3 + O_2 + 6H_2O \xrightarrow{\text{Leptothrix orchae}} \rightarrow$$
Ferrous carbonate

$$4Fe(OH)_3 + 4CO_2 + \text{Energy (81 k.cal)}$$
.

Hydrogen bacteria: These bacteria utilize free molecular hydrogen and oxidize to hydrogen into water with the help of either oxygen or oxidize salts e.g., Hydrogenomonas.

$$2H_2 + O_2 \rightarrow 2H_2O + \text{Energy}$$
 (56 kcal).

Ammonifying bacteria : They oxidise protein and amino acid into *NH*₃ (ammonia). *e.g.*, *Proteus vulgaris*, *Bacillus mycoids*.

Nitrifying bacteria: They oxidise ammonia to nitrites and then into nitrates.

$$NH_3+O_2 \xrightarrow{\text{Nitrosomonas}} NO_2+H_2O+\text{Energy}$$
 and
$$2NO_2+O_2 \xrightarrow{\text{Nitrobacter}} 2NO_3+\text{Energy} \;.$$

Denitrifying bacteria: They change nitrogen compound into molecular nitrogen. So that they reduce fertility of soil e.g., Micrococcus denitrificans, Pseudomonas denitrificans.

Methane bacteria: The bacterium *Methanomonas* utilizes methane as source of carbon and energy.

$$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O + \text{Energy}$$
.

Methane producing bacteria : These are spherical or rod shaped bacteria which produce methane (CH_4) from hydrogen gas and carbon dioxide e.g., Methanobacterium.

$$CO_2 + 4H_2 \longrightarrow CH_4 + 2H_2O$$

Methane (swamp gas) is produced under anaerobic conditions and can be used as a "biogas", otherwise it is a pollutant that contributes to the green house effect and global warming.

Carbon bacteria : These bacteria oxidize carbon monoxide into carbon dioxide and use the liberated energy, e.g., Bacillus oligocarbophilus.

$$2CO + O_2 \longrightarrow 2CO_2 + \text{Energy}$$
.

(3) **Heterotrophic bacteria**: Most of the bacteria can not synthesize their own organic food. They are dependent on external organic materials and require atleast one organic compound as a source of carbon of their growth and energy. Such bacteria are

called heterotrophic bacteria. Heterotrophic bacteria are of three types – Parasites, Saprotrophs and Symbionts.

(i) **Parasites**: They obtain their organic food or special organic compounds required for their growth from living cells of plants and animals. Some parasitic bacteria are relatively harmless and nonpathogenic, i.e., do not produce disease in hosts.

Table: 1.2-2 Human diseases

Disease	Casual organism
Paratyphoid	Salmonella paratyphi
Gastroenteritis	Salmonella sp. and Escherichia coli
Dysentery	Shigella dysenteriae, S. sonnei, S. boydii
Tularaemia	Francisella tularensis
Influenza	Haemophilus influenzae

Table: 1.2-3 Plant diseases

Disease	Casual organism
Black chaff of wheat	Xanthomonas translucens
Wilt of maize	Xanthomonas stewartii
Gummosis of sugarcane	Xanthomonas asculorum
Red stripe of sugarcane	Pseudomonas rubrilineans
Ring rot of potato	Corynebacterium
Canker of tomato	Corynebacterium michiganense
Leaf spot of Lady's finger	Xanthomonas esculenti
Hairy rot of apple	Agrobacterium rhizogenes
Black knot of grapes	Pseudomonas tumefaciens

(ii) Saprotrophic bacteria: These bacteria obtain their nutritional requirements from dead organic matter (such as animal excreta, corpses, fallen leaves, bread, fruits, vegetables, jams, jellies, etc.). These bacteria breakdown the complex organic matter into simple soluble forms by secreting exogenous digestive enzymes. Then they absorb the simple nutrient molecules and assimilate them. Aerobic break down of organic matter is called decomposition or decay. e.g., Pseudomonas.

(iii) **Symbiotic bacteria**: Symbiosis is the phenomenon in which the two organisms live in close association in such a way that both the partners get mutual benefit from this association. For example, a very well known nitrogen fixing bacteria – *Rhizobium* forms a symbiotic association with roots of leguminous plants (soyabean, clover, alfalfa, etc.) and producing root nodules.

Spirochaetes

These are free inhabitants of mud and water, and are chemoheterotrophic unicellular bacteria. These are spiral or helicoid in shape, covered by flexible cell wall and swim actively with flagella present at both pole or ends. Many diseases are caused by them as Treponema pallidum causes syphilis, Leptospira causes infectious jaundice and Borrelia causes relapsing fever. Besides some spirochaetes are found in teeth.

Archaebacteria

They are present in rumen (first part of stomach) of cattles. This is simplest and most primitive group of bacteria. The cell wall of these bacteria is made of polysaccharides and proteins (peptidoglycans and muramic acid are absent in cell wall). Archaebacteria are considered to be the 'oldest of living fossils'. Three main groups of archaebacteria are following.

(1) Methanogens: These are strict anaerobic bacteria and mainly occur in muddy areas and also in stomach of cattle, where cellulose is fermented by microbes. These are responsible for

UNIVERSAL BOOK DEPOT 1960

methane gas (CH_4) formation in bio-gas plants, because they have capacity to produce CH_4 from CO_2 or formic acid (HCOOH). e.g., Methanobacterium, Methanobacillus, Methanosarcina and Methanococcus.

- (2) **Salt lovers archaebacteria or Halophiles**: These are also anaerobic bacteria, which occur in extreme saline or salty conditions (upto 35% of salt or *NaCl* in culture medium). A purple pigmented membrane containing bacteriorhodopsin is developed in sun-light in these bacteria, which utilizes light energy for metabolic activities (different from photosynthesis). *e.g.*, *Holobacterium* and *Halococcus*.
- (3) **Thermoacidophiles**: These are the bacteria which are found in hot sulphur springs (upto $80^{\circ}C$). As against first two groups of archaebacteria, these are aerobic bacteria. These have the capacity to oxidize sulphur to H_2SO_4 at high temperature and high acidity (i.e., pH 2.0), hence given the name *Thermoacidophiles*, i.e., temperature and acid loving.

 $2S + 2H_2O + 3O_2 \rightarrow 2H_2SO_4 + \text{energy}.$

e.g., Sulfobolus, Thermoplasma, Thermoproteus.

Actinomycetes (Mycobacteria)

It is a group of unicellular branched filamentous bacteria which resemble fungal mycelia. They grow in the form of radiating colonies in cultures and therefore, commonly called **ray fungi**. They are Gram +ve chemo-organotrophic, saprotrophic bacteria. Most species are facultative anaerobic. These are generally present as decomposers in soil. The filaments are aseptate (non-septate) branched and very thin (about 0.2 to $1.2~\mu m$ in width). The wall contains mycolic acid. They reproduce asexually by means of conidia, which are produced at tips of filaments. The endospores are not formed. Most of these secrete chemical substances having antimicrobial activities called antibiotics. Some of the most common and effective antibiotics are obtained from the different species of the genus Streptomyces.

Table: 1.2-4

(1) Human disease	
Tuberculosis	Mycobacterium tuberculosis
Leprosy	Mycobacterium leprae
Buruli's ulcer	Mycobacterium ulcerans
Actinomycosis	Actinomyces israelii
Diphtheria	Corynebacterium diptheriae
(2) Animal disease	
Tuberculosis of cattle	Mycobacterium bovis
Lumpy jaw	Actinomyces bovis

Rickettsias (H.T. Ricketts 1909)

They are gram negative obligate pleomorphic but walled obligate intracellular parasites which are transmissible from arthropods. They are intermediate between true bacteria and viruses. Rickettsias require exogenous factors for growth. Cell wall is like typical bacterial wall. ATP synthesis is absent but ADP is exchanged with host cell ATP. They have genome and size (0.3-0.5 μm) smaller than true bacteria but have a longer generation time. Internally the cells of rickettsias contain DNA as well as RNA

in a ratio of 1:3.5. The cell walls contain muramic acid and are sensitive to lysozyme. Flagella, pili and capsule are absent. Reproduction occurs by binary fission. The natural habitat of rickettsias is in the cells of arthropod gut. They cause typhus group of fevers. Spread by droplet method, lice, ticks, fleas, etc.

Table: 1.2-5 Human diseases

Disease	Causal organism Rickettsia prowazekii.		
Typhus fever			
Rocky mountain spotted fever	Rickettsia rickettsii		
Q fever	Coxiella burnetti		

Chlamydiae

- (1) They are also called as PLT virus or basophilic virus or energy parasites (as they are not capable of ATP synthesis).
- (2) They are pathogenic only to birds and domestic or wild mammals.
- (3) They mainly cause keratoconjunctivitis and trachoma (leading to blindness).

Importance of bacteria

Bacteria are our 'friends and foes' as they have both useful and harmful activities.

Useful activities

(1) In agriculture or In soil fertility: Some bacteria increase soil fertility. Nitrogen is essential for all plants. Nitrogen occupies 80% of the atmosphere. The plants take nitrogen in the form of nitrates. In soil, nitrates are formed by three processes:

By nitrogen fixing bacteria: Bacteria are found in soil either free e.g., Azotobacter and Clostridium or in root nodules of leguminous plants e.g., Rhizobium leguminosarum. These bacteria are capable of converting atmospheric free nitrogen into nitrogenous compounds.

Nitrifying bacteria : These bacteria convert nitrogen of ammonia into nitrite (NO_2) e.g., nitrosomonas and convert nitrite compounds into nitrates e.g., nitrobacter.

Decay of dead plants and animals : Some bacteria attack on dead bodies of plants and animals and convert their complex compounds into simpler substances *e.g.*, *carbon dioxide* (CO_2) , water (H_2O) , nitrate (NO_3) , sulphate (SO_4) etc.

(2) **In dairy**: Bacterium lactici acidi and B. acidi lactici are found in milk. These bacteria ferment lactose sugar found in milk to form lactic acid by which milk becomes sour.

Lactic acid bacteria bring together droplets of *casein* a protein found in milk and help in the formation of curd.

Pasteurization: Milk is heated at 62.8°C for 30 min or 71.7°C. for 15 sec. only. This reduces the number of bacteria by killing all non spore forming bacteria and thus unboiled milk becomes sour earlier than boiled milk.

(3) In industries: From industrial point of view bacteria are most important. Some of the uses of bacteria in industries are as follows:

Vinegar industry: Vinegar is manufactured from sugar solution in the presence of *Acetobacter aceti*.

32 Monera (Prokaryotes)

Fibre retting : By this process fibres of jute, hemp and flax are prepared. In the preparation of flax, hemp and jute the retting of stems of *Linum usitatissimum* (Flax = Hindi Sunn), *Cannabis sativa* (Hemp = Hindi Patson) and *Corchorus capsularis* (Jute) respectively is done.

Tobacco industry: Bacillus megatherium is used for its fermentative capacity for developing flavour and taste in tobacco leaves.

Tea industry: By fermentative action of *Mycococcus* condisans curing of tea leaves is done. By this process special taste is developed in the tea leaves.

Tanning of leather: Some bacteria decompose fats which are found in skin of animal with the result that skin and hairs are separated from each other and this leather becomes ready for use.

(4) **In medicines**: Some of the antibiotics are manufactured by bacterial actions *e.g.*, *Bacillus brevis* – antibiotic thyrothricin and *B. subtilis* – antibiotic subtelin. Vitamin B₂ is manufactured by fermentative action of *Clostridium acetobutylicum*.

Antibiotics: These are the chemical substances produces by living microorganisms capable of inhibiting or destroying other microbes. These are the products of secondary and minor metabolic pathways, mostly secreted extracellularly by the microorganisms. These are used in controlling various infectious diseases.

Table: 1.2-6

Antibiotic	Obtained from		
Streptomycin	Streptomyces griseus		
Actidine	S. griseus		
Chloromycetin	S. venezuelae		
Tetracycline	S. aureofaciens		
Terramycin	S. rimosus		
Erythromycin	S. erythraeus		
Neomycin	S. fradiae		
Amphomycin	S. carus		
Trichomycin	S. hachijoensis		
Viomycin	S. floridae		
Bacitracin	Bacillus subtilis		
Gramicidin	B. brevis		
Tyrothricin	B. brevis		
Polymyxin	Bacillus polymyxa		

(5) Role of bacteria in petroleum pollution: Petroleum pollution in water bodies is checked upto some extent by Pseudomonas.

Genetically engineered strain of *Pseudomonas putida* (superbug) was developed by Dr. Ananda Mohan Chakraborty which biodegrade spilled oil. These superbugs were allowed by USA government in 1990 for removal of oil from water.

Harmful activities

- Cotton spoilage: It is done by bacteria called Spirochaete cytophage.
- (2) **Food poisoning :** Some saprotrophic bacteria cause decay of our food, i.e., they alter their normal form and induce unpleasant aroma, taste and appearance. Some bacteria produce powerful toxins in food to cause "**food poisoning**". Consumption of such food may cause serious illness or even death.

Botulism: It is caused by *Clostridium botulinum*. The main symptoms are vomiting followed by paralysis and death.

(3) **Spoilage of food :** Some examples of bacterial food spoilage are :

Greening on meat surface is caused by Lactobacillus and Leuconostoc. Souring of milk is caused by Lactobacillus and Streptococcus. Explosion of curd (gas production) is caused by Clostridium and Coliform bacteria. Ropiness (i.e., slimy milk) is caused by Klebsiella and Enterobacter sp.

- (4) **Pollution of water:** There are reports of epidemics of cholera, typhoid, jaundice and other infectious diseases, which were caused by polluted water. Many pathogenic bacteria such as, Vibrio cholerae, Salmonella typhi, Leptospira ceterohaemorrhagiae, etc. pollute water and make it unfit for drinking. These are eliminated by chlorination.
- (5) **Deterioration of textiles**: Some bacteria (e.g., Cytophaga, Vibrio and Cellulomonas) damage cellulose of textiles.
- (6) **Abortion :** Bacteria like *Salmonella* induce abortion in goats, horses, sheep etc.
- (7) Biological warfare: Some bacteria which cause diseases like anthrax, black-leg, tuberculosis etc, are employed as secret war agents.
- (8) **Denitrification:** Denitrification bacteria like *Bacillus licheniformis*, *Pseudomonas aeruginosa* convert nitrates and nitrites into free nitrogen, thus responsible for the process of denitrification. Thus soil is depleted of essential nutrient like usable form of nitrogen.
- (9) **Putrefaction :** It is the spoilage of protein in the absence of O_2 by the putrefying bacteria e.g., *Proteus*, *Mycoides*.
- (10) **Retting of fibres :** It is the hydrolysis of pectic substances that bind the cells together. e.g., Clostridium sp., Pseudomonas fluorescence.

Mycoplasma

Mycoplasmas were discovered by *E. Nocard* and *E. R Roux* (1898). They were first isolated from bovine sheep suffering from pleuropneumonia. They are often designated as pleuropneumonia-like organisms (PPLO). These organisms were later put under the generic name mycoplasma by *Nowak* (1929). In 1966 international committee of nomenclature of bacteria, placed mycoplasmas under the class *mollicutes*, which consists of two genera Mycoplasma and Acholeplasma.

Structure: These are the simplest and smallest unicellular non-motile known aerobic prokaryotes without cell wall. So that they can change their shape therefore called Jockers of microbiological park. Their size varies from $0.1-0.15~\mu m$. Due to the absence of the cell wall, these organisms are highly elastic and readily change their shape; hence the mycoplasmas are irregular and quite variable in shape. That is called pleomorphism. Mycoplasma cells are covered with three layered plasma membrane.

Unit membrane is made up of lipoprotein. The genetic material is a single, linear, double-stranded molecule of DNA, without a nuclear envelope. Unlike other prokaryotes, it is coiled throughout the cytoplasm. The cytoplasm contains the ribosomes which are 70S. It also contains RNA, proteins, lipids and many kinds of enzymes used in biosynthetic reactions. Mycoplasmas are gram-negative.

Physiology and reproduction: Mycoplasma are usually non-motile. They are sensitive to tetracycline and resistant to penicillin. These are destroyed usually by treatment of heat at 50° C for 6 hours mycoplasma are osmotically inactive. Mycoplasmas are heterotrophic in their mode of nutrition. Some of them are saprotrophs, but most of them are parasitic on plants and animals including man. They reproduce by budding or binary fission. Fragmentation specially in filamentous forms. Besides this, Mycoplasma reproduces by elementary cell bodies also. It is also called bleb particle. It is a kind of vegetative reproduction.

Importance of Mycoplasma

- (1) **Diseases in human beings**: *Mycoplamsa hominis* causes pleuropneumonia, inflammation of genitals and endocarditis, *etc. Mycoplasma pneumoniae* causes primary a typical pneumonia (PAP), haemorrhagic laryngitis, *etc. Mycoplasma fermentatus* and *M. hominis* cause infertility in man, otitis media (inflamation of middle ear).
- (2) **Diseases in animals :** Mycoplasma mycoides causes pneumonia in cattle. Mycoplasma bovigenitalum, causes inflammation of genitals in animals. Mycoplamsa agalactia causes agalactia of sheep and goat.
- (3) Diseases in plants: Common mycoplasmal diseases of plants are: Bunchy top of papaya, witches' broom of legumes, yellow dwarf of tobacco, stripe disease of sugarcane, little leaf of brinjal, clover phylloidy, big bud of tomato etc.

Cyanobacteria

The new name of cyanobacteria has been given to myxophyceae or cyanophyceae. Cyanobacteria form a group of ancient Gram negative, photosynthetic prokaryotes. Many botanists prefer to call them blue-green algae. They have survived successfully for about 3 billion years. They may cause water blooms.

Cyanobacteria are predominantly fresh water forms, a few are marine. They impart unpleasant taste and smell to the water. One species of cyanobacteria containing red pigment (*Trichodesmium erythraeum*) flourishes in red sea and is responsible for the red colour of its water.

Characteristics of Cyanobacteria

- (1) They have prokaryotic type of cells.
- (2) Cells do not have any organised nucleus. The nucleolus is absent and the nucleoid is not to be bounded by a nuclear membrane. The type of nucleus called incipient nucleus.
- (3) The photosynthetic pigments present in the cell are chlorophyll a, β carotene, myxoxanthophyll, myxoxanthin, C-phycocyanin and C-phycoerythrin. The C-phycocyanin is blue and C-phycoerythrin is red in colour. If C-phycocyanin is more as compared to C-phycoerythrin, it gives characteristic blue- green colour to the algae.
- (4) The photosynthetic pigment are present in lamellae, called thylakoids.
- (5) The presence of chlorophyll-a, cyanobacteria synthesis their own food from carbon dioxide and water in the presence of

- sunlight. Certain cyanobacteria fix atmospheric nitrogen in the presence of oxygen.
- (6) In cyanobacteria food is stored as cyanophycean starch or α -granules.
- (7) Some members possesses simple unbranched filament with heterocyst like Nostoc, Anabaena, Aulosira, Cylindrospermum etc.
- (8) Some members possesses simple unbranched filamentous forms without heterocysts and akinetes, e.g., Arthospira, Oscillatoria, Spirulina, Phormidium, Lyngbya, Symploca, Microcoleus, Schizothrix etc.
- (9) Cyanobacteria reproduce asexually by fission and fragmentation. Unicellular forms multiply by binary fission. Sexual reproduction is totally absent.
- (10) Cell wall is composed of a gelatinous sheath which is made up of three layers of microfibrils in which cellulose is not present.
- (11) Cells contain organelles like cyanophycean granules, gas vacuoles, polyhedral bodies, ribosomes, polyglucoside bodies, polyphosphate bodies etc.
- (12) Cyanobacteria are economically important because of having immense capability of fixing atmospheric nitrogen in the soil. An enzyme nitrogenase present in the heterocyst is responsible for the fixation of free nitrogen. Application of heterocysts bluegreen algae as biofertilizer enhances the production in paddy field crops. e.g., Anabaena, Nostoc, Cylindrospermum, Scytonema etc.

Economic importance of Cyanobacteria

Cyanobacteria have both beneficial and harmful effects in human affairs.

Useful activities

- (1) Growth of cyanobacteria in hard water is most probably responsible for the deposit of limestones.
- (2) Since they grow, photosynthesis, multiply and ultimately die, thus adding organic matter to the soil and increasing its fertility.
- (3) Whereas some cyanobacteria act to breakdown rock, the species that live in hot springs actually build rocks. This they accomplish by depositing salts of calcium and silica within the gelatinous sheath of the algal cell wall.
- (4) Balls of *Nostoc commune* are collected, boiled and consumed as food by the Chinese and South Americans. The prepared food is called 'Yoyucho'.
- (5) Some cyanobacteria, such as Anabaena, Lyngbya etc. help in conservation of soil, thus checking soil erosion.
- (6) Few species of Anabaena and Aulosira are inoculated in ponds to check the development of mosquito larvae.
- (7) Spirulina is cultivated in tanks to obtain protein rich animal food as well protein rich health food.

Harmful activities

- (1) Their most harmful effect is undoubtedly the formation of blooms in bodies of water.
- (2) They choke the intake of water supply systems and give the water a disagreeable odour giving a fishy taste to drinking water.
- (3) Many cyanobacteria produce toxins. They are directly or indirectly harmful for human. e.g., Nostoc, Anabaena, Microcystes etc.

34 Monera (Prokaryotes)

Nostoc

Habitat: *Nostoc* is found in aquatic and terrestrial habitat. The alga forms a jelly like mass in which numerous filaments are embedded. When young, they are more or less spherical, solid and microscopic in size. With advance in age, the colony grows and becomes macroscopic. In species like *N. amplissimum* it attains the diameter of 30cm or almost equals to the size of hen's egg in *N. punctiforme*. A number of species of *Nostoc* on soil. They often swell up and glisten after rains and therefore called fallen stars.

Morphology: The plant is filamentous and trichome are unbranched and appear moniliform..

All the cells of the trichome are similar in structure but at intervals are found slightly larger rounded, light yellowish, thick walled cells called as *heterocysts*. Trichome mostly breaks near heterocyst and forms hormogonia and thus they help in its multiplication.

Each cell trichome in *Nostoc* has primitive nucleus and chromoplasm and very much resembles in all details to a cyanophycean cell. Vacuoles and definite chromatophores are absent. The cell wall is differentiated into two layers. Outside the cell wall there is a mucilaginous sheath. Due to confluence of various mucilaginous sheaths of filaments, a mucilaginous colony is formed. The cell is *prokaryotic*.

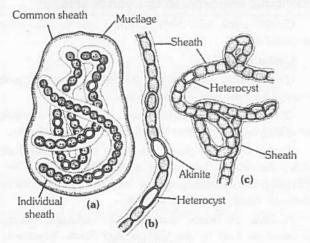

Fig: 1.2-3 Nostoc

Reproduction in Nostoc

There is no sexual reproduction in *Nostoc* but it reproduces asexually by following methods

- (1) Hormogonia: The filaments break at number of places into smaller pieces called as hormogonia by death and decay of an ordinary cell. They slip out of the mucilage sheath and grow into new plant. Frequently trichomes break near heterocysts.
- (2) **Resting spores or akinetes:** Under certain conditions some of the vegetative cells enlarge and accumulate food material and develop thick walls. These are called akinetes and may be arranged on either side of the heterocysts or in between two heterocysts. In mature akinete the outer wall may be 2–3 layered and its protoplasm becomes highly granular. The akinetes germinate after a period of rest and the contents are liberated out through a pore. The protoplast by further division forms the filament.

- (3) **Heterocysts**: In exceptional case like *N. commune* the heterocyst may become functional and on germination produces a new colony.
- (4) **Endospores**: Nostoc microscopium and Nostoc commune produce endospore.

Economic importance

- (1) Many species of *Nostoc* fix atmospheric nitrogen and thus increases soil fertility.
- (2) Reclamation of alkaline usar soils can be done by employing some species of *Nostoc*.
 - (3) N. commune is consumed as vegetable in China and Japan.

Tips & Tricks

- Pasteurization : Kills all non endospore forming bacteria.
- Insulin is the first hormone which obtained from genetically engineered bacteria.
- Free living No fixing bacteria Azotobacter and Polymyxa.
- Clostridium butyticum has been used in the synthesis of vitamin B.
- External DNA enters in bacteria through mesosomes.
- In bacteria flagella may be present, PS-II absent, photosynthesis is a nonoxygenic.
- Flagella of Salmonella bacteria contain H-antigens.
- Chemically E.coli has about 70% H₂O, 15% proteins, 6% RNA, 1% DNA. 2% Lipid, 3% carbohydrates, etc.
- May bacteria is Bacillus subtilis.
- Deodorants have salts of Zn and Al which kill bacteria causing odour.
- Alternation of generations is absent in bacteria due to absence of meiosis and syngamy.

Objective Questions

Structure, shape and nutrition of bacteria

- 1. Which of the following statement is correct [DUMET 2010]
 - (a) All bacteria are heterotrophic
 - (b) Bacteria are either heterotrophic or chemoautotrophic
 - (c) Bacteria can also be photoautotrophic
 - (d) Bacteria are either photoautotrophic or chemoautotrophic
- Bacteria were first discovered by [NCERT;
 CBSE PMT 1995; AFMC 1997; Kerala PMT 2000]
 - (a) Robert Koch
- (b) L. Pasteur
- (c) Robert Hooke
- (d) A.V. Leeuwenhoek

3.	On the basis of r-RNA genes bacteria are divided into [Odisha JEE 2008]	13.	the first americane between ordin positive and Ordin
	(a) Gram+ve and Gram-ve		regative bacteria lies in the composition of [NCERT; CBSE PMT 2001; Odisha JEE 2009; WB JEE 2011]
	(b) Bacteria and archaebacteria		(a) Cilia (b) Cell wall
			(c) Nucleolus (d) Cytoplasm
	(c) Actinomycetes and mycoplasma	14.	Muramic acid is present in the cell wall of
	(d) Cyanobacteria and mycolasma		[Pb. PMT 1999; BHU 2000; KCET 2001; CPMT 2009]
4.	In Escherichia coli [CBSE PMT 1993]		(a) Bacteria/Blue green algae (b) Green algae
	(a) An organised nucleus is present		(c) Yeast (d) Rhizopus
	(b) One chromosome is present	15.	[Find (Med.) 2012]
	(c) One DNA molecule is present		(a) Rod shaped (b) Spherical
	(d) One RNA molecule is present	16.	(c) Comma shaped (d) Spiral
5.		10.	Match the following pairs correctly and choose the right combination
Э.	Which of the following fixes CO_2 in carbohydrates		Column-I Column-II
	(a) Bacillus (b) Rhizobium		A. Escherichia coli 1. 'nif' gene
_	(c) Nitrobacter (d) Rhodospirillium		B. Rhizobium melilotae 2. Digests hydrocarbon of
6.	Bacteria are considered as plants, because		crude oil
	[CPMT 1994; BHU 2005]		C. Bacillus thurigiensis 3. Production of human insulin
	(a) These have a rigid cell wall		D. Pseudomonas putida 4. Biological control of fungal
	(b) They have a green colour		disease
	(c) They can reproduce		5. Bio-decomposed insectiside
	(d) They are present everywhere		(a) $A = 3$, $B = 1$, $C = 5$, $D = 4$
7.	Membrane-bound organelles are absent in		(b) $A = 1$, $B = 2$, $C = 3$, $D = 4$
	[CBSE PMT (Pre.) 2010]		(c) $A = 2$, $B = 1$, $C = 3$, $D = 4$
	(a) Plasmodium (b) Saccharomyces		(d) $A = 4$, $B = 3$, $C = 1$, $D = 2$
	(c) Streptococcus (d) Chlamydomonas		(e) $A = 3$, $B = 1$, $C = 5$, $D = 2$
8.	How many organisms in the list given below are autotrophs	17.	Helically coiled shaped bacteria are called[Odisha JEE 2008]
	Lactobacillus, Nostoc, Chara, Nitrosomonas, Nitrobacter,		(a) Spirilla (b) Cocci
	Streptomyces, Sacharomyces, Trypanosoma, Porphyra,		(c) Bacilli (d) Vibrio
	Wolfia [NCERT; CBSE PMT (Mains) 2012]	18.	Which of the following is a genetic vector [BVP 2001]
	(a) Four (b) Five		(a) Phage (b) Plasmid
	(c) Six (d) Three	19.	(c) Mosquito (d) None of these
9.	Gram -ve and +ve bacteria have cell membrane made up of	19.	Bacteria bearing flagella all over the body are called [CPMT 1999; BHU 2000; MP PMT 2001; MHCET 2003]
	[RPMT 1997]		(a) Peritrichous (b) Atrichous
	(a) Proteins and lipids (b) Cellulose		(c) Monotrichous (d) Cephalotrichous
	(c) Fats (d) Chitin	20.	The habitat of E. coli is [NCERT;
10.	Some hyperthermophilic organisms that grow in highly		RPMT 1995; EAMCET 1995; CBSE PMT 1998;

54.			th flagella arising from two		(a) Hairs (b) Flagella
	opposite ends, it is called	ided wi	in nagena arising from two		(c) Pili (d) Cilia
		· CPMT	2001, 10; MP PMT 2012]	66.	Which of the following is not correct statement about the
	(a) Monotrichous		Lophotrichous		plasmids [Odisha JEE 2011]
	(c) Amphitrichous		Polytrichous		(a) It is the extra chromosomal DNA in bacteria
55.			eria to attach to rocks and		(b) It is not a integral part but inert genetic material
	or host tissues are	ne vaci	[AIPMT 2015]		(c) Host chromosome can be integrated with the plasmid
	(a) Fimbriae	(b)	Mesosomes		(d) Transfer of plasmid can be done from cell to cell
	(c) Holdfast	200	Rhizoids		without killing the host
56.	What is a genophore	(4)		67.	Infoldings of the plasma membrane of gram positive
	(a) DNA in prokaryotes		[WB JEE 2011]		bacteria, gives rise to
		ine t-	730 11 15		(a) Clathrin (b) Chondritin
	(b) DNA and RNA in prol	200			
	(c) DNA and protein in p	rokaryo	les	60	
7	(d) RNA in prokaryotes			68.	Bacteria with tuft of flagella at one pole is known as
57.	An example of iron bacteri		[MP PMT 1999]		[Odisha JEE 2012]
	(a) Beggiatoa	1000	Geobacillus		(a) Amphitrichous (b) Peritrichous
	(c) Ferrobacillus	(d)	None of these		(c) Atrichous (d) Lophotrichous

- 69. Circular DNA molecule occurs in [NCERT; Pb. PMT 1994; MP PMT 1995, 98; CBSE PMT 1996; AIEEE Pharmacy 2003]
 - (a) Viruses
 - (b) Bacteria, chloroplasts and mitochondria
 - (c) Bacteria and chloroplasts only
 - (d) Bacteria only
- 70. Extension of plasma membrane in prokaryotes is[DPMT 2007]
 - (a) ER
- (b) Mesosome
- (c) Ribosome
- (d) None of these
- 71. Bacterial cells can be stained with
- [MP PMT 1999]
- (a) Mercuric chloride
- (b) Crystal violet
- (c) Crystal violet and iodine (d) Safranin
- 72. The term 'glycocalyx' is used for [NEET (Karnataka) 2013]
 - (a) A layer present between cell wall and membrane of bacteria
 - (b) Cell wall of bacteria
 - (c) Bacterial cell glyco-engineered to possess Nglycosylated proteins
 - (d) A layer surrounding the cell wall of bacteria
- 73. Why is a capsule advantageous to a bacterium

[NEET (Karnataka) 2013]

- (a) It protects the bacterium from desiccation
- (b) It provides means of locomotion
- (c) It allows bacterium to "hide" from host's immune system
- (d) It allows the bacterium to attach to the surface
- 74. According to the shapes the names of the different bacteria are given below. Identify them [NCERT]

- (a) A Spirilla, B Vibrio, C Cocci, D Bacilli
- (b) A Spirilla, B Bacilli, C Cocci, D Vibrio
- (c) A Bacilli, B Cocci, C Spirilla, D Vibrio
- (d) A Cocci, B Bacilli, C Spirilla, D Vibrio
- 75. Archaebacteria differ from eubacteria in [CBSE PMT 2014]
 - (a) Cell shape
- (b) Mode of reproduction
- (c) Cell membrane structure (d) Mode of nutrition
- Which structures perform the function of mitochondria in bacteria [CBSE PMT 2014]
 - (a) Cell wall
- (b) Mesosomes
- (c) Nucleoid
- (d) Ribosomes
- 77. Which one of the following matching pairs is WRONG

[WB JEE 2016]

- (a) Bacterial cell wall cellulose
- (b) Bacterial ribosome 16s rRNA
- (c) Bacterial flagella protein
- (d) Bacterial glycocalyx cellulose

- 78. Methanogens belong to
- [NEET (Phase-II) 2016]
- (a) Slime moulds
- (b) Eubacteria
- (c) Archaebacteria
- (d) Dinoflagellates
- Which of the following are found in extreme saline conditions [NEET 2017]
 - (a) Archaebacteria
- (b) Eubacteria
- (c) Cyanobacteria
- (d) Mycobacteria
- **80.** Which of the following components provides sticky character to the bacterial cell [NEET 2017]
 - (a) Cell wall
- (b) Nuclear membrane
- (c) Plasma membrane
- (d) Glycocalyx

Life cycle/Reproduction in bacteria

- Bacterial cell divides in every minute it takes one hour to fill up a cup. How much time will be taken to fill half the cup
 - (a) 59 minutes
- (b) 30 minutes
- (c) 60 minutes
- (d) 29 minutes
- 2. Under the optimum condition of temperature and nutrition most of the bacteria divide at the interval
 - (a) 24 hours
- (b) 20 minutes
- (c) 60 minutes
- (d) 5 minutes
- 3. Transformation experiments using *Pneumococcus* bacteria led to the hypothesis that [CBSE PMT 1993, 99]
 - (a) DNA is the genetic material
 - (b) Bacteria have sexual reproduction
 - (c) Chromosomes are made up of DNA
 - (d) RNA is the transfer link
- The process in which viruses are involved in sexual reproduction of bacteria is called [MP PMT 1996, 2011;

CPMT 1999, 2001; BHU 2000, 01, 08; JIPMER 2001; Haryana PMT 2005]

Or

The transfer of genetic material from one bacterial cell to another through a vector is [MH CET 2007]

- (a) Transduction
- (b) Transcription
- (c) Transformation
- (d) Translation
- 5. Bacteria commonly reproduce vegetatively by
 - [NCERT; WB JEE 2008]

Or

Which one of the following processes results in the formation of clone of bacteria [KCET 2010]

- (a) Binary fission
- (b) Budding
- (c) Conjugation
- (d) Oidia
- 6. Some bacteria are not easily killed because of
 - (a) Chitinous wall
- (b) Endospore formation

[EAMCET 2009]

- (c) Presence of mesosome
 - (d) High tolerance
- Identify the correct pair of events when temperate phages infect bacteria
 - I. No prophages are formed
 - II. Bacterial cell undergoes many divisions
 - III. Bacterial cell undergoes immediate lysis
 - IV. Prophages are formed
 - The correct pair is
- (b) II, III
- (a) I, II (c) III, IV
- (d) II, IV
- Why the food can be kept for a longer time in cold house than in normal conditions
 - (a) Insect can not enter
 - (b) Bacterial multiplication stops
 - (c) Bacterial multiplication is reduced
 - (d) There is plasmolysis at low temperature

Monera (Prokaryotes) 39 UNIVERSAL BOOK DEPOT 1

			BOOK DEPOT 1950
9.	Viral genome incorporated and integrates with bacterial genomes is refer to as [AFMC 2005]	19.	
	(a) Prophages (b) RNA		[Netala CL1 2001]
			(a) Conjugation (b) Transformation (c) Transduction (d) Transcription
10.	1-	20.	
10.	- Production in capacitoria takes place by		(a) F–replicon (b) Chromosomal replicon
	(a) Conjugation (b) Transduction		(c) RNA (d) Sex pilis
	(a) Conjugation (b) Transduction (c) Transformation (d) All of these	21.	Amitosis is shown by [CPMT 2010]
11.			(a) Bacteria (b) Euglena
	of Diplococcus Pneumoniae when mixed with heat killed	00	(c) Syllis (d) Hydra
	S-type is called [MPPMT 1997, 98, 2000, 09;	22.	[MF FM1 2000]
	Kerala PMT 2000, 09; CBSE PMT 2002;		(a) Endospores (b) Transformation (c) Conidia (d) Exospores
	DUMET 2010; MHCET 2015]		
	Or	1000	Economic importance of bacteria
	The uptake of naked DNA by bacteria is called	1.	Consider the following four statements (1-4) and select the
	[WB JEE 2016]		option which includes all the correct ones only
	(a) Mutation (b) Transduction		(1) Single cell Spirulina can produce large quantities of
	(c) Transfection (d) Transformation		food-rich in protein, minerals, vitamins etc
12.	There is no alternation of generation in Escherichia coli because there is no		(2) Body weight-wise the microorganism Methylophilus methylotrophus may be able to produce several times
			more proteins then the cows per day
	(a) Syngamy (b) Reduction division		(3) Common button mushrooms are a very rich source of
	(c) Conjugation (d) None of these		vitamin C
13.	Penicillin inhibits bacterial multiplication because [CPMT 1998; Odisha JEE 2008]		(4) A rice variety has been developed which is very rich in calcium
	(a) It checks spindle formation		Options [CBSE PMT (Mains) 2012]
	(b) It destroys chromatin		(a) Statements (3), (4)
	(c) It inhibits cell wall formation		(b) Statements (1), (3) and (4) (c) Statements (2), (3) and (4)
	(d) It checks RNA synthesis	*)	(c) Statements (2), (3) and (4) (d) Statements (1), (2)
14.	Pili in bacteria represent [BHU 2001]	2.	A free living anaerobic bacterium capable of N_2 fixation in
	(a) Extra-chromosomal genetic element		soil is [RPMT 1995; MP PMT 1996, 2006;
191	(b) Protoplasmic outgrowths of donor cells		BHU 1998, 2012; HPMT 2000]
	(c) Small flagella		(a) Rhizobium (b) Azotobacter
	(d) Special bacterial cilia		(c) Streptococcus (d) Clostridium
15.	The process of replication in plasmid DNA, other than initiation, is controlled by [RPMT 1999]	3.	Which of the following is free-living aerobic non- photosynthetic nitrogen fixing bacterium [CBSE PMT 1997;
	(a) Plasmid gene (b) Bacterial gene		BHU 2002, 03, 08; J & K CET 2005, 08;
	(c) Cytoplasmic gene (d) Mitochondrial gene		DUMET 2009; Odisha JEE 2010; MP PMT 2012]
16.	The guts of cow and buffalo possess		(a) Rhizobium (b) Azotobacter
	[AIPMT (Cancelled) 2015]		(c) Nostoc (d) Azospirillum
	(a) Chlorella spp. (b) Methanogens	4.	Which of the following groups of plants are highly useful in
	(c) Cyanobacteria (d) Fucus spp.		increasing soil fertility
17.	Transfer of genetic information from one bacterium to		(a) Red algae (b) Fungi
	another in the transduction process is through	-	(c) Bacteria (d) Bryophytes
	[CBSE PMT 1998]	5.	A prokaryotic autotrophic nitrogen fixing symbiont found in
	(a) Physical contact between donor and recipient strains		[NCERT; CBSE PMT (Pre.) 2011]
	(b) Conjugation between opposite strain bacterium		Or Bosidos paddu fields grandhadain and find the
	(c) Bacteriophages released from the donor bacterial strain		Besides paddy fields, cyanobacteria are also found inside vegetative part of [NEET 2013]
	(d) Another bacterium having special organ for conjugation		(a) Pisum (b) Alnus
18.	Conjugation in bacteria was discovered by [MP PMT 2000]		(c) Cycas (d) Cicer
	Or	6.	Curing of tea leaves is brought about by the activity of
	The sexuality in bacteria was established by [MP PMT 1996]		[CBSE PMT 2006]
	(a) Robert Koch (b) Schaudinn and Hoffmann		(a) Viruses (b) Fungi
	(c) Lederberg and Tatum (d) Leeuwenhoek		(c) Bacteria (d) Mucorrhiza

- 7. Oxygenic photosynthesis occurs in [CBSE PMT 2009]
 - (a) Chromatium
- (b) Oscillatoria
- (c) Rhodospirillum
- (d) Chlorobium
- 8. Thermococcus, Methanococcus and Methanobacterium exemplify [CBSE PMT 2008]
 - (a) Bacteria whose DNA is relaxed or positively supercoiled but which have a cytoskeleton as well as mitochondria
 - (b) Bacteria that contain a cytoskeleton and ribosomes
 - (c) Archaebacteria that contain protein homologous to eukaryotic core histones
 - (d) Archaebacteria that lack any histones resembling those found in eukaryotes but whose DNA is negatively supercoiled
- The symbiotic nitrogen fixing bacteria present in root nodules of legumes belong to genus [NCERT;

AFMC 1998; CPMT 1998;

CBSE PMT 1999; Pb. PMT 1999; BVP 2002; Kerala CET 2003; MP PMT 2003; MHCET 2004; AIEEE Pharmacy 2004; Bihar CECE 2006; DUMET 2009; J & K CET 2010]

- (a) Xanthomonas
- (b) Pseudomonas
- (c) Rhizobium
- (d) Acetobacter
- 10. Nitrogen fixing bacteria are associated with
- [NCERT]

- (a) Leguminosae
- (b) Cruciferae
- (c) Gramineae
- (d) Malvaceae
- Which of the following is recently discovered gram positive non-leguminous nitrogen fixing bacterium

[AIEEE Pharmacy 2003]

- (a) Azospirillum
- (b) Rhizobium
- (c) Nitrosomonas
- (d) Spirillum
- 12. Nitrifying bacteria, Nitrosomonas and Nitrobactor

[CPMT 2004; Odisha JEE 2010; CBSE PMT (Pre.) 2011]

- (a) Convert (oxidise) ammonia or ammonium compounds into nitrates
- (b) Convert nitrate into nitrogen
- (c) Convert nitrogen into nitrates
- (d) Convert carbon dioxide into carbohydrates
- Match the items in column I with those in column II and choose the correct answer

	Column I		Column II
P.	Blue green algae as biofertilizers	i.	Ectomycorrhiza
Q.	Fungi as biofertilizers	ii.	Thiobacillus sp
R.	Free living nitrogen fixing bacteria	III.	Anabaena sp
S.	Phosphate solubilizing bacteria	iv.	Clostridium sp
	Called Land	v.	Azospirillum sp
		v.	rizospiriiu

[WB JEE 2012]

- (a) P-iii, Q-i, R-v, S-ii
- (b) P-v, Q-i, R-ii, S-iv
- (c) P-v, Q-iv, R-i, S-ii
- (d) P-iv, Q-ii, R-v, S-iii

- The most abundant prokaryotes helpful to humans in making curd from milk and in production of antibiotics are the ones categorised as [CBSE PMT (Pre.) 2012]
 - (a) Cyanobacteria
 - (b) Archaebacteria
 - (c) Chemosynthetic autotrophs
 - (d) Heterotrophic bacteria
- **15.** During biological nitrogen fixation, inactivation of nitrogenase by oxygen poisoning is prevented by

[AIPMT 2015]

- (a) Xanthophyll
- (b) Carotene
- (c) Cytochrome
- (d) Leghaemoglobin
- 16. Free living bacteria that can fix N_2 from soil is

[Odisha JEE 2012]

- (a) Clostridium
- (b) Azotobacter
- (c) Beijerinckia
- (d) All of these
- 17. For retting of jute the fermenting microbe used is

[CBSE PMT 2005]

- (a) Methophilic bacteria
- (b) Butyric acid
- (c) Helicobactor pylori
- (d) Streptococcus lactin
- **18.** Which bacteria is responsible for the reduction of nitrates into nitrogen, (denitrifying Bacteria) in soil

[Odisha JEE 2005; Kerala PMT 2010; AMU (Med.) 2010; MP PMT 2010; J & K CET 2012]

- (a) Nitrosomonas
- (b) Pseudomonas
- (c) Rhizobium
- (d) Clostridium
- 19. Which of the bacterium is useful in preparing Idli [BVP 2003]
 - (a) Leuconostoc mesenteroides
 - (b) Clostridium
 - (c) Both (a) and (b)
 - (d) None of the above
- Which of the following is symbiotic nitrogen fixes
 - [DPMT 2006; CBSE PMT 2009]

Or

Which of the following can fix nitrogen in non-leguminous plants [WB JEE 2016]

- (a) Streptomyces
- (b) Anabaena
- (c) Frankia
- (d) Rhizobium
- 21. Non-symbiotic nitrogen fixation takes place by

[GUJCET 2014]

- (a) Nostoc, Azotobacter, Clostridium
- (b) Anabena, Nostoc, Rhizobium
- (c) Azotobacter, Nitrosomonas, Rhizobium
- (d) Anabena, Nitrosomonas, Pseudomonas
- 22. All of the following statements concerning the actinomycetous filamentous soil bacterium Frankia are correct except that Frankia [CBSE PMT 2005]
 - (a) Can induce root nodules on many plant species
 - (b) Cannot fix nitrogen in the free-living state
 - (c) Cannot fix specialized vesicles in which the nitrogenase is protected from oxygen by a chemical barrier involving triterpene hapanoids
 - (d) Like Rhizobium, it usually infects its host plant through root hair deformation and stimulates cell proliferation in the host's cortex

- Contract			
			Monera (Prokaryotes) 41
23.	Organisms called Methanogens are most abundant in a [CBSE PMT (Pre.) 2011] (a) Hot spring (b) Sulphur rock	35.	The function of leghaemoglobin in the root nodules of legumes is [NCERT; CBSE PMT (Pre.) 2011] (a) Expression of nif gene
24.	(c) Cattle yard (d) Polluted stream Plasmid are used as carrier because		(b) Inhibition of nitrogenase activity (c) Oxygen removal
	[CBSE PMT 2000; AIIMS 2007] (a) It has antibiotic resistance genes (b) Its both ends are replication points	36.	(d) Nodule differentiation A large number of organic compounds can be decomposed by
	(c) It can go between eukaryotic and prokaryotic cells (d) It is circular DNA which has capacity to bind eukaryote DNA		(a) Chemoorgano (b) Pseudomonas
25.	Fermentation is by [RPMT 1999] (a) All micro organism	37.	(c) Acetobacter (d) Mycoplasma Which one of the following bacteria has potential fo nitrogen fixation [MP PMT 1995; Bihar MDAT 1995
	(b) All fungi(c) All bacteria(d) Some fungi and some bacteria		(a) Nitrosomonas (b) Nitrobacter (c) Nitrosococcus (d) Rhizobium
26.	Cattle ranches are known to cause acute green house effect. This is due to [AIIMS 2012]	38.	nitrates into nitrites and then to free nitrogen and such bacteria are termed as
	(a) Mechanised milking practices(b) Methanogenic bacteria in rumen(c) Decomposition of left over fodder		(KCET 2000; CPMT 2003; AFMC 2006 Or
27.	(d) Decomposition of organic remains in faeces Which does not help in N_2 fixation [RPMT 1999]		The bacteria which convert NO ₃ → Free N ₂ are called as [CPMT 1994, 2003; MP PMT 1996; MHCET 2003 (a) Nitrogen fixing bacteria (b) Denitrifying bacteria
28.	(a) Anabaena (b) Nostoc (c) Oscillatoria (d) Rhizobium Which of the following is non-symbiotic biofertilizer	39.	(c) Ammonifying bacteria (d) Saprophytic bacteria Which of the following is a flowering plant with nodule containing filamentous nitrogen-fixing microorganism
out has	(a) VAM (b) Azotobacter		(a) Casuarina equisetifolia (b) Crotalaria juncea
29.	(c) Anabaena (d) Rhizobium Which bacteria convert ammonium salts into nitrite [CPMT 1998] (a) Nitrobacter (b) Nitrosomonas	40.	(c) Cycas revoluta (d) Cicer arietinum Probiotics are [CBSE PMT 2007; DUMET 2010] (a) Safe antibiotics (b) Cancer inducing microbes
30.	(c) Azotobacter (d) None of these Which of the following soil microorganism breaks down		New kind of food allergens Live microbial food supplement
	plant and animal protein into ammonia [KCET 1998] (a) Bacillus vulgaris (b) Nitrosomonas (c) Pseudomonas (d) None of the above	41.	nitrogen compounds are called [AFMC 1996]
31.	Which of the following is used to cure off the bitterness of tea leaves [CPMT 1999; JIPMER 2001]	100	(c) Nitrogen fixing bacteria (d) Nitrifying bacteria
20	(a) Bacillus subtilis (b) B. megatherium (c) B. lactis (d) B. mycococcus	1.	Bacterial diseases The germ theory of disease was putforth by [MP PMT 1995]
32.	One of the useful activities of several bacteria is [MP PMT 1998] (a) Nitrogen fixation		(a) Koch (b) Pasteur (c) Rayer (d) Devaine
	(b) Nitrification(c) Operation of biogeochemical cycles	2.	Effective management practice for bacterial leaf blight of rice is [Odisha JEE 2012] (a) Removal of secondary host weed
33.	(d) All of the above The main role of bacteria in the carbon cycle involves [CBSE PMT 1998; AIIMS 2000]		(b) Use of resistant varieties (c) Treatment of ZnSO ₄ and CaOCl ₂
	(a) Photosynthesis(b) Assimilation of nitrogenous compounds(c) Chemosynthesis	3.	(d) All of the above In the following table identify the correct matching of the crop, its disease and the corresponding pathogen [AIIMS 2008]
34.	(d) Digestion or breakdown of organic compounds One of the free-living, anaerobic nitrogen-fixer is [CBSE PMT (Pre.) 2010]		Crop Disease Pathogen (a) Citrus Canker Pseudomonas rubrilineans (b) Potato Late blight Fusarium udum
	Or Which of the following is a photoautotrophic bacterium		(c) Brinjal Root-knot. Meloidogyne incognita (d) Pigeon pea Seed gall Phytophthora infestans
	(a) Azotobacter (b) Beijernickia (c) Rhodospirillum (d) Rhizobium	4.	Cause of 'Mad Cow' disease of England [RPMT 1999] (a) Virions (b) Mycoplasma (c) Scrapie Protein (d) Viral protein

5.	Which of the following is a bacterial plant disease [Odisha JEE 2010]	patenta	Mycoplasma
	(a) Tikka disease of groundnut	1.	Which one is the smallest organism capable of autonomous
	(b) Downy mildew of grapes		growth and reproduction [MP PMT 2001; BHU 2012]
	(c) Ring rot of potato		Or
	(d) Red rot of sugarcane		Which among the following are the smallest living cells
	Mycolic acid is present in cell wall of pathogen causing		known without a definite cell wall, pathogenic to plants as
	(a) Tetanus (b) Cholera		well as animals and can survive without oxygen[NEET 2017
	(c) Diphtheria (d) Tuberculosis		(a) Virus (b) Viroid
	Tetanolysin is produced by	0	(c) Mycoplasma (PPLO) (d) None of the above Little leaf of brinjal is caused by
	(a) Mycobacterium laprae (b) Clostridium botulinum	2.	[Bihar MDAT 1995; MP PMT 2001
			(a) Virus (b) Mycoplasma
	(c) Clostridium tetani (d) None of these		(c) Fungus (d) Algae
	Bacterial blight of rice is caused due to	3.	Which one of the following statements about mycoplasma is
	[Odisha JEE 2004; CBSE PMT 2008]	cupini	wrong [MP PMT 2002; CBSE PMT 2007
2	(a) Xanthomonas oryzae (b) Helminthosporium oryzae		(a) They are also called PPLO
	(c) Pseudomonas falcatum (d) Xanthomonas falcatum		(b) They are pleomorphic
	The poisonous substances commonly produced by bacteria		(c) They are sensitive to penicillin
	are known as [Kerala CET 2002; AFMC 2003]		(d) They cause diseases in plants
	(a) Toxin (Exotoxins) (b) Auxins	4.	What is incorrect for mycoplasma [RPMT 1997]
	(c) Antibiotic (d) Antitoxins		(a) They are osmotically inactive
0.	Which one of the following pathogen cause canker disease		(b) Show absence of cell wall
	[MP PMT 2002, 10; Kerala PMT 2007]		(c) Are sensitive to modern antibiotics
	(a) Meloidogyne incognita (b) Anguina tritici		(d) Are obligate intracellular parasites
	(c) Xanthomonas citri (d) Pseudomonas rubilineans	5.	Prokaryota includes [RPMT 1995; CBSE PMT 1996
	(e) Phytophthora infestans		JIMPER 2002; MP PMT 2004
1.	The Bacillus haemophilus causes		(a) Mycoplasma
	(a) Influenza (b) Pneumonia		(b) Ulothrix
	(c) A form meningitis (d) Whooping cough		(c) Fungi
2.	Black rot of crucifers is caused by a [AMU (Med.) 2012]	,	(d) Mycoplasma and blue-green algae
77.0	(a) Fungus (b) Bacterium	6.	Penicillin and Vancomycin do not affect the mycoplasma because [Odisha JEE 2008
	(c) Virus (d) None of these		(a) There is no cell wall (b) There is no nucleus
3.	Which of the following is disease causing bacterium in		(c) There is no mitochondria (d) There is no golgi body
	human beings [MP PMT 2002]	7.	Which of the following is effective against mycoplasma
	(a) Escherichia coli (b) Xanthomonas citri	10, 10	diseases
	(c) T.M.V. (d) Pilobolus		(a) Vancomycin (b) Penicillin
4.	"Crown gall" is caused by [BHU 1995; CPMT 1998]		(c) Chloramphenicol (d) All the above
	(a) Mycobacterium	8.	Which of the following is called "Jockers of microbiological
	(b) Agrobacterium tumefaciens		park"
	(c) Erwinia		(a) Bacteria (b) Mycoplasma
	(d) Clostridium		(c) Nostoc (d) None of these
5.	Which is the cause of Anthrax disease [MP PMT 2002]	9.	The 'Witches broom' of legumes is caused by a
	(a) Virus (b) Bacteria		[MP PMT 1994; RPMT 1995; KCET 1999; Pb. PMT 2004
	(c) Mycoplasma (d) Algae		(a) Virus (b) Mycoplasma
6.	'Citrus canker' is caused by a	COMPAN	(c) Bacterium (d) Fungus
	[NCERT; MP PMT 1997; BVP 2000; AFMC 2008]	10.	Elementary cell body in mycoplasma perform the function o
	(a) Fungus (b) Bacterium		[RPMT 1995; MP PMT 1995, 98
	(c) Virus (d) Nematoda		(a) Metabolism (b) Excretion (c) Reproduction (d) Respiration
7.	The 2005 noble prize for physiology/medicine was awarded	11.	Mycoplasma are not sensitive to [MP PMT 2000]
	to Barry Marshall and Robin Warren of Australia for their		(a) Streptomycin (b) Penicillin
	discovery of [KCET 2011]		(c) Erythromycin (d) Neomycin
	(a) Human papilloma virus causing cervical cancer	12.	Which of the following statement is true for Mycoplasma
	(b) Bacterium Helicobacter pylori causing peptic ulcer		[MP PMT 1999; KCET 2015; AIPMT 2015
	(c) Prions, a new biological principle of infection		(a) Presence of cell wall (b) Presence of nucleus
	(d) Human immunodeficiency virus		(c) Absence of cell wall (d) Definite shape
			No.

13.	Who recorded pleuropneumonia in cattles	3.	Which of the following h	as polar nodule	on both the ends
	(a) Pasteur (b) Twort		(a) Akinetes	(b) Horn	
	(c) Knoll and Ruska (d) Nocard and Roux		(c) Heterocysts		
14.	"Dodder" can transmit	4.	Which of the following sl		
	(a) Mycoplasmal diseases (b) Viral diseases	•	winer of the following si	nows the absent	
	(c) Both (a) and (b) (d) None of these		(a) Green algae	(b) Pad s	[DPMT 2006
15.	Which of the species of mycoplasma causes human sterility		(c) Blue-green algae	(b) Red a	
	(a) M. hominis (b) M. fermentans	5.		(d) Brow	
	(c) Both (a) and (b) (d) None of these	3.	Which of the following p	iants is used as	
16.	The outermost limiting layer of mycoplasma is made up of		(a) Mastas	41 5	[Kerala CET 2005
10.			(a) Nostoc	(b) Funa	
	(a) Cell wall (b) Cell membrane		(c) Volvox	(d) Rhizo	
	(c) Mucilaginous sheath (d) Slime layer	6.	The most primitive in the		[BHU 2005
17.	The membrane of which one of the following micro-		(a) Cyanobacteria	(b) Bryor	
17.	organism is three layered	_	(c) Gymnosperms	(d) Mono	
	(a) Nostoc (b) Mycoplasma	7.	Which of the following sta		[KCET 2004
	(c) E. coli (d) Rhodospirillum		(a) Fronds are found in	bryophytes	
18.	The disease of cardio-vascular system is caused by		(b) Multiciliate sperms a	re found in angi	osperms
10.			(c) Diatoms produce ba	sidiospores	
	(a) Algae (b) Mycoplasma		(d) Heterocysts are foun		
10	(c) Cyanobacteria (d) None of these	8.	Cyanobacteria are		T 2002; BVP 2004]
19.	Tendency of abortion in ladies is caused by [MP PMT 2007]		(a) Mosses which attack		1 2002, BVF 2004]
	(a) Cyanobacteria (b) Bacteria				
00	(c) Mycoplasma (d) None of these		(b) Bacteria which attack		
20.	Which disease is caused by mycoplasma		(c) Autotrophic organism	n with phycocya	nnin
	(a) Citrus greening (b) Sandal spike		(d) None of these		
01	(c) Grassy shoot of sugarcane (d) All the above	9.	Nitrogen fixation by Nost	oc/Anabaena ta	kes place in
21.	Mycoplasma is		[NCERT; MP	PMT 1996; Od	isha JEE 2004, 09;
	(a) Gram positive		AFN	MC 2009; NEET	(Karnataka) 2013]
	(b) Gram negative		(a) Heterocysts	(b) Vegeta	
	(c) Some species are gram positive		(c) Akinetes	(d) Horme	
22.	(d) None of the above	10.	Which of the following ma		
22.	PPLO reproduce (multiply) by		which of the following the		NCERT; BVP 2004]
	(a) Gametic fusion (b) Binary fission (c) Akinetes (d) Endospore		(a) Bacteria	(b) Mycop	
23.			(c) Virus		
20.	An organism having cytoplasm DNA and RNA but no cell wall is [MP PMT 1995, 98; CPMT 2000;	11		(d) Blue-g	Marie Control of the
	BVP 2001; MHCET 2002]	11.	Which of the following is a	not a blue-greer	-
	(a) Cyanobacterium (b) Mycoplasma				[CPMT 2004]
	(c) Bacterium (d) Virus		(a) Nostoc	(b) Anaba	
24.	Mycoplasma is related to		(c) Lichen	(d) Aulosii	
	(a) Algae (b) Bacteriophage	12.	The blue-green algae are		
	(c) Virus (d) L–form bacteria		to green pigment chloroph		
25.	Organisms without any specific shape are [MP PMT 1997]		[KCET 1994;	MP PMT 1996;	Kerala PMT 2003]
	(a) Mycoplasmas (b) Bacteria		(a) Phycocyanin	(b) Chrom	oplasm
	(c) Viruses (d) Cyanobacteria		(c) Cyanophycin	(d) Phycoe	erythrin
650000		13.	Red sea phenomena due t		[RPMT 2006]
a state	Cyanobacteria / Blue green algae		(a) Red algae		[111 1-11 2000]
L.	Pigment phycocyanin and phycoerythrin are found in				
	[Kerala CET 2005, BHU 2008]				
	(a) Bacillariophyceae (b) Archaebacteria		(c) Diatoms		
	(c) Eubacteria (d) Cyanobacteria		(d) Blue-green algae (Tric	chodesmium erg	othrium)
	(e) Chlorophyceae	14.	Which of the following m	novement may	be found in blue-
2.	Incipient nucleus is present in [BVP 2000]		green algae		
	(a) Chlorophyceae (b) Rhodophyceae		(a) Flagellar	(b) Ciliary	
	(c) Myxophyceae (d) Phaeophyceae		(c) Gliding	(d) None of	of the above

15.	Which of the following important features are found in blue-	27.	Sexual reproduction is absent in [MP PMT 2000]
13.	green algae [MP PMT 2006]	21.	(a) Cyanobacteria .(b) Bacteria
	(a) Abundant secretion of pectin		(c) Eukaryote (d) All of the above
	(b) Presence of phycocyanin – C as dominant pigment	28.	Prokaryotes are characterized by
	(c) No plastids		[Bihar MDAT 1995; CPMT 2009]
	(d) All the above		 (a) A true nucleus with double layered nuclear membrane is absent
16.	Which was first photosynthetic organism [DPMT 2003] (a) Green algae (b) Red algae		 (b) Well developed nucleus with double layered nuclear membrane present
	(c) Cyanobacteria (d) Brown algae		(c) Presence of cell wall made of chitins,
17.	Which of the following is a Prokaryote [MP PMT 2002] (a) Chlorella (b) Chlamydomonas		mucopolysaccharides and absence of nuclear membrane and cell organelles like mitochondria and
	(c) Protomyces (d) Oscillatoria		chloroplasts (d) Autotrophic in nature and only DNA is present
18.	What is the photosynthetic product in blue-green algae (a) Normal starch	29.	One of the followings is not the characteristic feature of cyanobacteria [AMU (Med.) 2010]
	(b) Glycogen		(a) They are multicellular
	(c) Cyanophycean starch resembling glycogen		(b) They form colonies
	(d) None of these		(c) They form blooms in polluted water bodies
19.	Which is not a cyanobacterium [AFMC 2002]		(d) They can fix atmospheric nitrogen
	(a) Lyngbya (b) Plectonema	30.	The name cyanobacteria refers to
	(c) Anabaena (d) Sinorhizobium		[NCERT; CPMT 2002; CBSE PMT (Pre.) 2012]
20.	The characteristic of blue green algae is		(a) Bacteria (b) Blue-green algae
	[NCERT; CBSE PMT 1999; RPMT 1999, 2002]		(c) Yeast (d) Fungi
	Or more marked to the control of the	31.	Nuclear membrane is absent in [CBSE PMT (Pre.) 2012]
	Blue- green algae are called cynobacteria because		(a) Penicillium (b) Agaricus
	[MP PMT 2012]	00	(c) Volvox (d) Nostoc
	(a) DNA without histone	33.	Which one of the following statements is wrong [NEET (Phase-I) 2016]
	(b) Nuclear membrane absent		(a) Cyanobacteria are also called blue-green algae
	(c) 70 S ribosomes		(b) Golden algae are also called desmids
	(d) All of the above		(c) Eubacteria are also called false bacteria
21.	Cyanobacteria of great nutritive value is [Kerala CET 2001]		(d) Phycomycetes are also called algal fungi
	(a) Gleocapsa (b) Scytonema	34.	Which were the organisms who changed earth's surface
	(c) Stigonema (d) Spirulina		from reducing to the oxidizing [BHU 2001]
22.	Nitrogenase enzyme is found in Nostoc in the cell of		(a) Autotrophs (b) Heterotrophs
	[MP PMT 2001]		(c) Photoautotrophs (d) Chemotrophs
	(a) Vegetative (b) Heterocyst (c) Both (a) and (b) (d) None of these	35.	Cyanobacteria originated about how many years ago [Pb. PMT 2000]
23.	Nostoc is known to perform [MP PMT 2001]		(a) 1 billion (b) 2 billion
	(a) Only photosynthesis		(c) 3 billion (d) 4 billion
	(b) Photosynthesis and nitrogen fixation simultaneously(c) Only nitrogen fixation	36.	Which of the following statements is not true for Nostoc [KCET 2012]
	(d) Either photosynthesis or nitrogen fixation at a time		(a) It is prokaryotic (b) It is autotrophic
24.	Single filament of <i>Nostoc</i> without mucilage sheath is known as [AIIMS 1998]	37.	(c) It is filamentous (d) It is macroscopic During rainy seasons, the ground becomes slippery due to dense growth of [BHU 1999]
	(a) Hyphae (b) Colony		dense growth of [BHU 1999] (a) Lichens (b) Bacteria
	(c) Trichome (d) Mycelium		(c) Green algae (d) Cyanobacteria
25.	In which of the following there is no sexual reproduction [CBSE PMT 1995, 99; BVP 2001]	38.	Hormogonia are the vegetatively reproducing structures of [AIIMS 1999]
	(a) Ulothrix (b) Nostoc		(a) Ulothrix (b) Spirogyra
	(c) Aspergillus (d) Volvox		(c) Oscillatoria (d) Chlamydomonas
26.	Which of the following algae is symbiotic and nitrogen fixing [Pb. PMT 1999]	39.	Atmospheric nitrogen-fixation is carried on by [Pb. PMT 1999; HP PMT 2005]
	(a) Spirogyra (b) Cladophora		(a) Funaria (b) Anabaena
	(c) Anabaena (d) Oedogonium		(c) Chlamydomonas (d) Fern gametophyte

UNIVERSAL BOOK DEPOT 1960

40. Spirulina is a [CPMT 2010] 4. K_{12} plasmid was studied first in (a) Blue green algae (b) Fungi (a) E. coli (b) Shigella (c) Pteridophyte (d) Bryophyte (c) Salmonella (d) Eberthella 41. Cyanophyceae has got (a) Definite nucleus and plastid destroys (b) No definite nucleus but plastid (a) Certain fungi (c) Neither definite nucleus nor plastid (b) Certain types of bacteria (d) Definite nucleus but no plastid (c) All viruses Nostoc is a [MP PMT 1999: MHCET 2007] (d) Most virus - infected cells (a) Cyanobacteria (b) Beaded bacterium The most throughly studied of the known bacteria-plant 6. (c) Bacteriophage (d) Parasite interactions is the 43. Unicellular cyanobacteria reproduce asexually by (a) Nodulation of Sebania stems by nitrogen fixing bacteria [MP PMT 1997] (a) Conjugation (b) Fragmentation (c) Binary fission (d) Hormogones (c) Cyanobacterial symbiosis with some aquatic ferns 44. Heterocysts are found in certain (d) Gall formation on certain angiosperms by Agrobacterium [MP PMT 1997; Kerala PMT 2010] (a) Viruses (b) Bacteria Which one of the following is genetically improved bacteria (c) Cyanobacteria (d) Mycoplasmas for pollution control 45. Pigment-containing membranous extensions in some (a) Pseudomonas (b) Rhizobium cyanobacteria are [NEET 2013] (c) Nitrobacter (d) Nitrosomonas (a) Chromatophores (b) Heterocysts 8. Otitis media (inflammation of middle ear) is caused by (c) Basal bodies (d) Pneumatophores (a) Virus (b) Bacteria 46. Nostoc is characteristic in having **IMP PMT 19981** (c) Bacteriophage (d) Mycoplasma (a) Cellulose cell wall (b) Uniflagellated zoospores 9. (c) Chlorophyll 'e' (d) Sexual reproduction regarding the characteristics of certain organisms (A) Methanogens are Archaebacteria which produce Critical Thinking methane in marshy areas (B) Nostoc is a filamentous blue-green algae which fixes Objective Ouestions atmospheric nitrogen Escherichia coli has the following combination of characters 1. (C) Chemosynthetic autotrophic bacteria (a) Rod shaped, 1-3 μm long, gram negative cellulose from glucose (b) Rod shaped, 1–3 μm long, gram positive (c) Spiral, 1-3 µm long, gram negative oxygen (d) Spiral, 1-3 μm long, gram positive The correct statements are [CBSE PMT (Mains) 2010] Mycoplasma differs from virus in being sensitive to (a) (B), (C) (b) (A), (B), (C) [MP PMT 1995] (c) (B), (C), (D) (d) (A), (B), (D) (a) Sugar (b) Tetracycline (c) Protein (d) Amino acid chemicals in their surroundings by Which one of the following is wrong statement [Kerala CET 2000; WB JEE 2008]

[CBSE PMT (Pre.) 2012]

(a) Anabaena and Nostoc are capable of fixing nitrogen in free living state also

- (b) Root nodule forming nitrogen fixers live as aerobes under free living conditions
- (c) Phosphorus is a constituent of all membranes, certain nucleic acids and all proteins
- (d) Nitrosomonas and Nitrobacter are chemoautotrophs

- Lysozyme that is present in perspiration, saliva and tears, [CBSE PMT 2007]
- [CBSE PMT 2004]

 - (b) Plant growth stimulation by phosphate-solubilising bacteria
- [CPMT 1998]
- Select the correct combination of the statements (A-D)

 - synthesize
 - (D) Mycoplasma lack a cell and can survive without

The gram negative bacteria detect and responsed to

- (a) Lipopolysaccharide
- (b) Muramic acid
- (c) Porins
- (d) Volutin granules
- A few organisms are known to grow and multiply at 11. temperatures of 100 - 105°C. They belong to

[CBSE PMT 1998]

- (a) Thermophilic subaerial fungi
- (b) Marine archaebacteria
- (c) Thermophilic sulphur bacteria
- (d) Hot spring blue-green algae

A bacterium divides every 35 minutes. If a culture containing 105 cells / ml is grown for 175 minutes. What will be the cell concentration / ml after 175 minutes

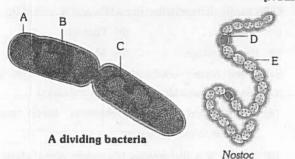

[CBSE PMT 1998; BHU 2004]

- (a) 175 × 105 cells
- (b) 85×10^5 cells
- (c) 35×10^5 cells
- (d) 32 × 105 cells
- 13. Monera possess

IMP PMT 20131

- (a) Membrane bound nucleoproteins lying free in the cutoplasm
- (b) Gene containing nucleoproteins condensed together in compact masses
- (c) Nucleoproteins in direct contact with the rest of the cell substance
- (d) Only free nucleic acid aggregates
- 14. Which of the following are likely to be present in deep sea [NEET 2013]
 - (a) Saprophytic fungi
- (b) Archaebacteria
- (c) Eubacteria
- (d) Blue-green algae
- Identify the A, B, C, D and E in the following diagram

[NCERT]

- (a) A Cell membrane, B Cell wall, C DNA, D -Heterocyst, E - Mucilagenous sheath
- (b) A Mucilagenous sheath, B Cell membrane, C -DNA, D - Heterocyst, E - Cell wall
- (c) A Cell wall, B Cell membrane, C DNA, D -Heterocyst, E - Mucilagenous sheath
- (d) A Cell wall, B Cell membrane, C Heterocyst, D -DNA, E - Mucilagenous sheath
- The motile bacteria are able to move by [CBSE PMT 2014]
 - (a) Cilia
- (b) Pili
- (c) Fimbriae
- (d) Flagella
- Pick up the wrong statement
- [AIPMT 2015]
- (a) Protista have photosynthetic and heterotrophic modes of nutrition
- (b) Some fungi are edible
- (c) Nuclear membrane is present in monera
- (d) Cell wall is absent in animalia
- 18. Cyanobacteria are classified under [NCERT]
 - (a) Protista
- (b) Plantae
- (c) Monera
- (d) Algae

- Conversion of nitrate to ammonia is a/an [WB JEE 2016]
 - (a) Amination process
- (b) Deamination process
- (c) Oxidative process
- (d) Reductive process
- Select the mismatch 20.
- [NEET (Phase-II) 2016]
- (a) Methanogens-Prokaryotes
- Gas vacuoles-Green bacteria
- (c) Large central vacuoles-Animal cells
- (d) Protists-Eukaryotes
- 21. Select the wrong statement

[NEET (Phase-II) 2016]

- (a) Mycoplasma is a wall-less microorganism
- (b) Bacterial cell wall is made up of peptidoglycan
- (c) Pili and fimbriae are mainly involved in motility of bacteria cells
- (d) Cyanobacteria lack flagellated cells
- Spliceosomes are not found in cells of

[NEET 2017]

- (a) Plants
- (b) Fungi
- (c) Animals
- (d) Bacteria

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- If the assertion is true but the reason is false (c)
- (d) If both the assertion and reason are false
- If the assertion is false but reason is true (e)
- Assertion Bacteria are prokaryotic.
 - - Reason Bacteria do not possess true nucleus and

membrane bound cell organelles.

- [AIIMS 1996]
- Assertion Bacteria have three basic shapes, i.e., round, rod, spiral.

- Reason Cocci and Bacilli may form clusters or chain of a definite length. [AIIMS 2000]
- 3. Assertion Bacterial photosynthesis occurs by utilizing wavelength longer than 700 nm.
- Reason Here reaction centre is B-890. [AIIMS 2002]
- Assertion The nitrogen-fixing bacteria in leguminous plant nodules live as symbionts.
 - Reason Leg-haemoglobin synthesized by leguminous plants protect bacteria.
- Assertion Bacteria are classified among plants.
 - Reason They have cell walls.
- Assertion Bacteria do not always move with the help 6. of flagella.
 - Reason Flagellated bacteria employs rotary motion of flagellum when it moves.
- 7. Assertion Some bacteria have the capacity to retain
 - Gram stain after treatment with acid alcohol. Reason They are known as Gram positive as they
 - are attracted towards positive pole under influence of electric current.

8.	Assertion	:	None autotrophic bacteria carry out chemosynthesis.
	Reason	:	Chemosynthetic bacteria trap the small amount of energy released from inorganic compound's oxidation to use in the reactions that synthesize carbohydrates.
9.	Assertion	:	Exotoxins are released by Gram +ve bacteria causing diseases to animals.
	Reason	:	Exotoxins are proteins to whose response WBC of animals react.
10.	Assertion	:	All food chains will come to stand still if bacteria disappear from earth.
	Reason	:	Bacteria are only associated with the soil fertility and hardly any role for food chains.
11.	Assertion	:	Broad spectrum antibiotics are produced by streptomyces.
	Reason	:	They can destroy microorganisms by inhibiting DNA replication or protein synthesis.
12.	Assertion	1	Bacterial cell wall is characterised by having mucopolysaccharides.
	Reason	:	Acetyl muramic acid is an example of mucopolysaccharide.
13.	Assertion	:	Root nodules in leguminous plants are inhabited by Anabaena.
	Reason		Leguminous plants are an example of symbiotic nitrogen fixation.
14.	Assertion	:	Bacillus butschli is true bacterium.
	Reason	;	Its cell wall is composed of acetyl muramic acid.
15.	Assertion	:	Plasmids are double-stranded extra chromosomal DNA.
	Reason	:	Plasmids are possessed by eukaryotic cells. [AIIMS 1997]
16.	Assertion	:	Pili are motile appendages of bacteria.
	Reason	:	Pili participate in conjugation.
17.	Assertion	:	Cell secretion does not occur in bacteria.
	Reason	:	Golgi complex is absent in bacteria.
18.	Assertion	;	Agrobacterium tumefaciens is the causative

Structure, shape and nutrition of bacteria

- (d) Rhodospirillium is photosynthetic bacteria.
- (c) Nostoc, Chara, Porphyra and Wolfia are Photoautotrophs while Nitrosomonas and Nitrobacter are chemoautotrophs.

- 13. (b) In G⁺ (Gram-positive bacteria) cell wall is 200–300 Å thick having mucopeptides 85% and lipids 1–2% while in G⁻ (Gram-negative bacteria) cell wall is 100–200 Å thick and mucopeptides are 10–12% and lipids 80–90%.
- 23. (c) E. coli is a prokaryotic bacterium.
- 25. (a) Anaerobic breakdown of proteins is known as putrefaction.
- 29. (c) In many bacteria (specially gram +ve) the plasma membrane gives rise to infoldings called mesosome. They have respiratory enzymes like succinic dehydrogenase, cytochrome oxidase for respiration.
- 33. (a) The bacterial flagellum is long, filamentous and protoplasmic appendage that arise in the cell envelope. In the bacterial flagella instead of 9 + 2 arrangement of tubulin there is simply a single filament of globular protein called flagellin.
- 39. (d) Nitrifying bacteria such as Nitrosomonas and Nitrobacter manufacturing their organic food utilizing chemical energy in oxidation of some inorganic compound. Hence these bacterias are chemosynthetic.
- 40. (a) Branched chain lipids of cell membranes of archaebacteria enable them to tolerate high temperature and high acidity.
- **44.** (b) During unfavourable condition highly resistant single spore is formed in the bacterial cell (e.g., Tetanus and anthrax bacteria) which is known as endospore.
- 52. (d) The bacterium E. coli have double stranded circular DNA. Many genetical researches are carried out on E. coli for the study of genetic engineering.
- 55. (a) Fimbriae are more in number, short thin straight bristle like appendages which function as organ of adhesion. Pili are similar to fimbriae but different in function.
- **59.** (d) R-factor is type of plasmid which contains genes for antibiotic resistance.
- (c) Respiratory enzyme containing infolding of plasma membrane in bacteria called chondrioid.
- 72. (d) The cell envelope in bacteria consists of a tightly bound three layered structure i.e. the glycocalyx followed by the cell wall and then plasma membrane.
- (c) Cell membrane of archaebacteria possesses branched chain lipids.
- 76. (b) Mesosomes help in respiration, secretion processes, to increase the surface area of the plasma membrane and enzymatic contact.

- 77. (a) Bacterial cell wall is made of peptidoglycan.
- (c) Methanogens, halophiles and thermoacidophiles are archaebacteria.

Life cycle/Reproduction in bacteria

- (a) The number of bacteria becomes double after each division.
- (a) In the process of transduction, virus is used as a carrier in the transfer of DNA from one bacterial cell to other.
- 7. (d) Temperate phages are the avirulent lysogenic phages whose nucleic acids get incorporated in the bacterial DNA (lysogenization). When these phages infect bacteria, the bacterial cell undergoes many divisions and prophages are formed.
- 9. (a) The phage λ DNA attaches to the specific site of bacterial genome with the help of λ integrase enzyme. The phage DNA in this latent (non virulent) form is called provirus or prophage (integrated viral DNA with the host bacterial DNA).
- 19. (a) During conjugation two bacteria cell comes together and formed a conjugation tube. By this tube genetic material reach from donor to recipient bacteria.
- 20. (a) Sex factor or F-factor are extra-chromosomal DNA particles which either integrate with main DNA or remain independent from main DNA.
- (b) It takes place by transferring DNA from capsulated to non-capsulated.

Economic importance of bacteria

- (d) Spirulina is SCP rich in protein, vitamins and minerals and rice variety rich in iron content. 250 gram biomass of Methylophilus methylotrophus produce 25 tonn protein/day while cow of 250 Kg produces only 200gm protein/day.
- (d) Clostridium is saprophytic, anaerobic N₂ fixing bacteria and have ability to fix atmospheric N₂ into NH₃.
- 3. (b) Azotobacter (aerobic) is a free living N₂, fixing bacteria. This bacteria fix independently atmospheric nitrogen in their body and convert to organic nitrogen compounds. When they die, the organic nitrogen compounds of their body are made available to higher plants through the activities of other bacteria.
- (c) Bacteria causes N₂ fixation.
- (c) Anabaena cycadae is a BGA found in coralloid roots of Cycas.
- (c) Bacteria causes the curing of tea and coffee by which bitterness is removed and flavour is added.

- 17. (b) In this process bacteria decompose the pectin of the plant to liberate fibres. The process of fibre preparation is known as retting. This process is carried out by Clostridium butyrium.
- 18. (b) Some bacteria such as Thiobacillus denitrificans, Pseudomonas aoruginosa and Micrococcus denitrificans also occur in the soil which convert the nitrate and ammonia into atmospheric free elemental nitrogen.
- 20. (c) Actinomycetes are filamentous bacteria, inhabitant of soil. The genus Frankia causes nitrogen fixing nodules to form in older tree roots (non-legume plants).
- 21. (a) Non-symbiotic nitrogen fixation takes place by Bluegreen algae (Nostoc and Anabena) and free living soil bacteria (the aerobic Azotobacter species and the anaerobic Clostridium species).
- 23. (c) Methanogens are archaebacteria abundant in cattle yard and paddy fields.
- 27. (c) They lack heterocyst. That is why, they can not take part in N₂ fixation.
- **28.** (b) Non-symbiotic bacteria are also called free-living nitrogen fixing bacteria *e.g. Azotobacter*. They are agriculturally important.
- **29.** (b) $NH_4 \xrightarrow{Nitrosomonas} NO_2 \xrightarrow{Nitrobacter} NO_3$.
- 32. (d) Some bacteria can fix atmospheric N₂ like Azotobacter and Clostridium, some bacteria can change nitrogen of ammonia into nitrate like Nitrosomonas and some bacteria help in biogeochemical cycle by breaking of complex organic compound into simple inorganic compound.
- 33. (d) The main role of bacteria is as a decomposer. The bacteria decompose the complex organic compounds into simple one which are reused in carbon cycle.
- 34. (a) Rhodospirillum bacteria is facultative aerobic photo-autotrophic bacteria use non-sulphur aliphatic organic compound as donor of H₂ e.g., Propyl alcohol.
 6CO₂ + 12CH₃CHOHCH₃ Light → C6H₁2O6 + 12CH₃COH₃ + 6H₂O
- 35. (c) LHB is O2 scavanger.
- 39. (a) Frankia is a filamentous N₂-fixing bacteria which is symbiont on the root of Casuarina equisetifolia.

Bacterial diseases

- (b) On the basis of his work Pasteur proposed "germ theory of disease" which was recognised by medical scientists very soon.
- (d) Mycobacterium tuberculosis releases the mycolic acid, it is changed to mycoides involved in causing disease.
- 7. (c) Tetanolysin is a Neurotoxins.
- 15. (b) Bacteria Bacillus anthracis caused anthrax disease.

Mycoplasma

- (b) Little leaf of brinjal: In this disease, the leaves of Brinjal remain small in size because mycoplasma inhibits leaf expansion of leaf cells.
- (d) Mycoplasma can grow out side the host cell. Thus it is clear that mycoplasma are not obligate parasite like viruses.
- (a) Penicillin and vancomycin inhibits the cell wall synthesis.
- 10. (c) Elementary bodies are related with asexual reproduction of mycoplasma. When cell of mycoplasma divides into minute bodies, these bodies are called elementary bodies.
- (b) Because mycoplasma lacks cell wall where as penicillin acts on cell wall.
- (c) Cuscuta reflexa (Dodder) is parasite on angiosperms through which viruses and mycoplasma transmit.
- 16. (b) Mycoplasma lacks cell wall, therefore the outermost existing layer is cell membrane.
- (c) Mycoplasma salivarium inhibit the food as well as blood to the developing embryo in pregnant female, which cause abortion.
- (b) Mycoplasma is irregular in shape and divides by simple binary fission.
- 23. (b) Mycoplasma are cell wall less cells but show multiplication like bacteria, so that they are termed as cell wall less bacteria.
- 24. (d) Both mycoplasma and L-form bacteria are cell wall less.
- 25. (a) Due to the absence of cell wall, mycoplasma are highly elastic and readily change the shape, hence the mycoplasmas are irregular and quite variable in shape. This nature is called pleomorphism.

Cyanobacteria / Blue green algae

- (d) Cynobacteria have a water soluble phycobilin pigments. c-phycocyanin (blue) and c-phycoerythrin (red).
- (c) Myxophyceae is another name of cyanobacteria which are moneran.

- 3. (c) Each heterocyst is connected with vegetative cells, on two sides through the prominent pores into the wall. Which later on one occupied by a refractive cynophycean granule called polar nodule.
- **4.** (c) Chlorophyll-b is found in eukaryotic photoautotroph.
- (a) Nostoc possess special type of cells called heterocyst for free N₂ fixation that is why Nostoc is biofertliser.
- (a) Heterocysts are airtight anaerobic bodies in which enzyme nitrogenase fixes atmospheric nitrogen.
- 14. (c) Cilia and flagella absent in blue green algae.
- 19. (d) Sinorhizobium is a bacterium.
- (d) Blue green algae or cyanobacteria is designated as Prokaryotes.
- (d) Spirulina is a rich source of proteins and vitamin Bcomplex as well.
- **23.** (b) Because they have photosynthetic lamellae for photosynthesis and heterocyst for N_2 -fixation.
- **26.** (c) Anabaena is found symbiotically in Azolla and help in N_2 fixation.
- (a) Cyanobacteria is haploid so meiosis and fertilization is absent.
- 31. (d) Because Nostoc is prokaryotes
- 33. (c) Cyanobacteria appeared in precambrian period around 3.2 billion years ago and were the first to have oxygenic photosynthesis to evolve O_2 in photosynthesis that caused conversion of primitive reducing atmosphere to present day oxidising atmosphere (oxygen revolution).
- **42.** (c) Unicellular forms reproduce asexually by binary fission while filamentous forms are by Hormogones.
- **43.** (c) Some cyanobacteria possess heterocyst like *Nostoc*, *Scytonema* etc. Heterocyst is a site of *N*₂ fixation.

Critical Thinking Questions

- (b) Mycoplasma are sensitive to tetracycline and resistant to penicillin, because they lack cell wall.
- (a) K₁₂ plasmid was first studied in E.coli, by two American scientist Lederberg and Tatum (1946).
- (b) Lysozyme is a enzyme which can dissolve the cell wall of bacteria.
- (a) Genetically modified Pseudomonas can decompose organic product like petroleum, oils etc.
- (d) Chemosynthetic autotrophs oxidize inorganic substances to produce energy and helps cycling of minerals.
- 10. (c) Porins is a proteins, which is found in the cell of Gram negative bacteria. Which function as channels for the entry and exist of hydrophilic low molecular weight substances.

12. (d) As we know that bacterium divides after every 35 minutes through simple mitotic division therefore number of divisions are $\frac{175}{35} = 5$

Since one bacterium on division produces two cells so cell concentration after 175 minutes will be $=10^{5} \times (2)^{5} = 32 \times 10^{5}.$

- (d) Motile bacteria have thin filamentous extensions from their cell wall called flagella.
- 20. (c) Large central vacuole is present in plant cells
- 21. (c) Motility is performed by flagella only in bacterial cells while fimbriae provide attachment to base and pili form conjugation tube during conjugation

Assertion and Reason

- (a) Bacterial cell is prokaryotic. It lacks true nucleus, membrane bound organelles and sexual reproduction.
- (b) Bacteria have different shapes spherical, rod, and spiral are three important type. Cocci may be in cluster or chain form or single and bacilli may be single, in pair in chain.
- 3. (b) Bacteria utilize the wavelengths longer than 700 nm for photosynthesis and the reaction centre is P-890 the reductant is NADH + H⁺. In bacteria donor may be H₂S or malate or succinate.
- 4. (a) Rhizobium form a symbiotic association with roots of leguminous plants producing root nodules. These bacteria reside inside the nodules and reduce atmospheric nitrogen (N₂) to ammonia. The fixed nitrogen is taken up by plant. In return the plant provides nutrients both and protection to bacteria.
- 5. (a) Plant cells are characterized by the presence of a rigid cell wall on the basis of which they can be differentiated from animal cells. Hence classified among plants.
- (b) Myxobacteria do not have flagella and move by gliding movement.
- 7. (c) The cell wall of Gram-negative bacteria contains alcohol-soluble lipid, while the cell wall of Gram-positive bacteria lacks the lipids and therefore resist decolourisation and retain the primary stain, appearing violet. Gram-negative bacteria are decolorized by organic solvents and therefore, take the counter stain, appearing red. Gram +ve bacteria does not attracted towards positive pole under influence of electric current.

- 8. (d) Chemosynthetic bacteria are without photosynthetic pigments. For the synthesis of their own organic food, (carbohydrates), they obtain carbon from CO₂ of the atmosphere, necessary energy from oxidation of inorganic or organic compounds, such as hydrogen sulphide (H₂S), ferrous compounds (Fe²⁺), molecular hydrogen (H₂) ammonia (NH₃) and nitrites (NO₂⁻).
- (a) Mostly pathogenic gram +ve bacteria releases exotoxins outside the cell and kills the W.B.C. and causes the disease.
- 10. (c) The bacteria play an important and dual role by disposing off the dead bodies and wastes of organism and by increasing the fertility of soil.
- (a) Streptomyces produced broad spectrum of antibiotics by living microorganism capable of inhibiting or destroying other many types of microbes.
- 12. (d) Chemically bacteria consists of acetylglycosamine, acetyl muramic acid and a peptide chain of four or five amino acids. All these chemicals together form a polymer called peptidoglycan (= murein or mucopeptide). Some other chemical substances deposited on the cell wall are teichoic acid, protein polysaccharides lipoproteins and lipopolysaccharides.
- (a) Anabaena found symbiotically in the root nodules of many leguminous plants which helps in N₂ fixation.
- (a) Bacillus butschli is the Gram positive bacterium and its cell wall consist of acetyl muramic acid.
- 15. (c) In addition to bacterial chromosomes many bacteria have accessory rings of DNA called plasmids. Plasmids are absent in eukaryotic chromosome.
- 16. (e) In some bacteria, nonmotile appendages called pili or fimbriae are also present. They take part in sexual reproduction, i.e., conjugation.
- (e) Cell secretion occurs even in the prokaryotic cells (bacteria) in relation to the production of a variety of enzyme to the medium. In certain protozoa, vacuoles similar to the contraction expel water into the medium. Golgi complex are found, which by their contraction expel water into the medium. Golgi complex and other membrane found organelle are absent in prokaryotes.
- 18. (a)

ET Self Evaluation Test

- 1. Which of the following represents obligate anaerobes
 - (a) Spirogyra
- (b) Pisum sativum
- (c) Onion
- (d) Methane bacteria
- Mycoplasma mycoides causes which of the following diseases
 - (a) Bovine pleuropneumonia (b) Inflammation of genitals
 - (c) Agalactia
- (d) None of these
- 3. Food material can be preserved at
- [MP PMT 2006]
- (a) High temperature
- (b) Osmotic pressure
- (c) Low temperature
- (d) All of the above
- The bacteria which lacks flagella and moves by gliding are included in
 - (a) Spirochaetes
- (b) Rickettsia
- (c) Myxobacteria
- (d) Eubacteria
- 5. Select the correct match

A.	Nitrosomonas	-	Nitrite to nitrate
B.	Thiobacillus	-	Denitrification
C.	Nostoc	-	Free-living nitrogen-fixer
D.	Azotobacter	-	Anaerobic nitrogen-fixer

[Kerala PMT 2011]

- (a) A and B
- (b) C and D
- (c) B and C
- (d) B and D
- (e) A and C
- Pasteurization is heating at

[MP PMT 2006 DUMET 2009; CPMT 2009]

- (a) 120°C for 60 minutes
- (b) 60-70°C for 30 minutes
- (c) 70°C for 60 minutes
- (d) 80°C for 30 minutes
- 7. Exotoxin is produced by
 - (a) Gram positive bacteria
- (b) Gram negative bacteria
- (c) Both (a) and (b)
- (d) None of the above
- 8. Clover phyllody is caused by
- [MP PMT 2011]
- (a) Spirochaetes
- (b) Protoplasts
- (c) Spheroplasts
- (d) Mycoplasmas
- **9.** The murein found in bacterial cell is
- [CPMT 1998]
- (a) Derivative of protein
 - (b) Derivative of fat
 - (c) Derivative of organic acids
 - (d) Derivative of sugars
- 10. Koch's postulates are not applicable to [CBSE PMT 1999]
 - (a) T.B.
- (b) Leprosy
- (c) Cholera
- (d) Diphtheria
- 11. The purple sulphur bacteria use hydrogen sulphide and release sulphur but not oxygen. Which of the following agrees with above observation [AIEEE Pharmacy 2002]
 - (a) The H_2 that reduces CO_2 comes from H_2S that liberates sulphur
 - (b) Photosynthesis does not require chlorophyll
 - (c) Photosynthesis consist of a light and a dark reaction
 - (d) The H₂ which reduces CO₂ in photosynthesis comes from H₂O that releases O₂

- Why bacteria do not survive in the salt pickle which has high salt contents [KCET 2000]
 - (a) Salt retards the rate of reproduction of bacteria
 - (b) Bacteria do not get light for photosynthesis
 - (c) Due to plasmolysis bacteria die
 - (d) Essential elements for bacterial viability are not present in the pickle
- For reproduction, 'endospores' are formed in the following genera [BHU 1994; KCET 1999; Pb. PMT 2000]
 - (a) Bacillus and Clostridium
 - (b) Mucor and Bacillus
 - (c) Monococcus and Clostridium
 - (d) Saccharomyces and Clostridium
- 14. Match column I with column II and select the correct option given below

	Column I	1	Column II
A.	Aerobic	1.	Frankia
B.	Cyanobacteria	2.	Azospirillum
C.	Casuarina -	3.	Clostridium
D.	Tropical grasses	4.	Aulosira
		5.	Azotobacter

[Kerala PMT 2006]

- (a) A-4, B-3, C-2, D-1
- (b) A-3, B-5, C-4, D-2
- (c) A-2, B-1, C-3, D-5
- (d) A-5, B-3, C-4, D-1
- (e) A-5, B-4, C-1, D-2
- 15. Which bacterium causes cotton destruction
 - (a) Clostridium botulinum
 - (b) Spirochaeta cytophaga
 - (c) Mycobacterium
 - (d) Vibrio
- Bacteroids are

[MP PMT 2010]

- (a) Enlarged non-motile cellular bacteria Rhizobium leguminosarum in root nodules of legumes
- (b) A bacterial cell infected with viruses
- (c) A motile bacterium
- (d) Nitrosomonas bacteria in soil
- Activity of nitrogenase in nitrogen fixing micro-organisms can be seen when
 - (a) Methane is converted to ethane
 - (b) Ethane is converted to methane
 - (c) Ethylene is converted to acetylene
 - (d) Acetylene is converted or reduced to ethylene

18. Azotobacter and Polymyxa are example of

[CBSE PMT 1996]

- (a) Symbiotic nitrogen fixation
- (b) Non-symbiotic nitrogen fixation
- (c) Disease causing bacteria
- (d) Ammonifying bacteria
- Match the types of bacteria listed in column I with their activity given in column II. Choose the correct combination of alphabets of the two columns

(Column-I Types of bacterial)	Column-II (Activity)					
A.	Streptomyces	p.	Food poisoning				
B.	Rhizobium	q.	Source of antibiotics				
C.	Nitrosomonas	r.	Nitrogen fixation				
D.	Acetobacter	S.	Nitrification				
		t.	Vinegar synthesis				

[NCERT; KCET 2004]

- (a) A = q; B = r; C = p; D = t
- (b) A = q; B = r; C = s; D = t
- (c) A = s; B = t; C = p; D = r
- (d) A = t; B = p; C = r; D = s
- 20. The bacteria Pseudomonas is useful because of its ability to

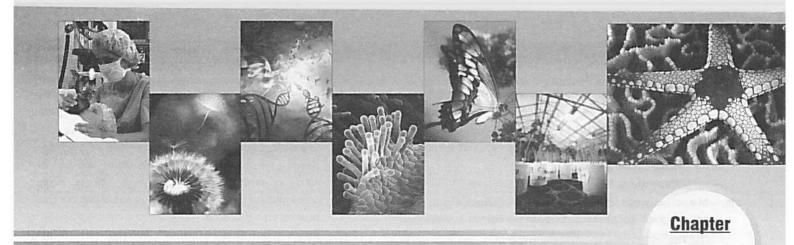

[AIIMS 2004]

- (a) Transfer genes from one plant to another
- (b) Decompose a variety of organic compounds
- (c) Fix atmospheric nitrogen in the soil
- (d) Produce a wide variety of antibiotics
- 21. Pullorum disease of poultry is caused by [KCET 2000]
 - (a) Hemophilus
- (b) Clostridium
- (c) Salmonella
- (d) Mycobacterium
- 22. Which of the following is a seed borne disease [DPMT 2004]
 - (a) Bacterial blight of rice
 - (b) Kharia of paddy
 - (c) Whiptail of Brassica
 - (d) All of these

Answers and Solutions

1	d	2	a	3	d	4	C	5	c
6	b	7	a	8	d	9	d	10	b
11	a	12	c	13	a	14	е	15	b

21	c	22	a						

- (d) Food preservation and spoilage of food involve the factors that control the growth of microorganisms.
 These methods of preservation are used today.
 - Osmotic pressure-The addition of salts of a solution resulting in increase of osmotic pressure and can be used to preserve food. The high salt or sugar concentration draw water of any microbial cell out thus prevent their growth.
 - Low-temperature—Pathogenic bacteria with a few exception will not grow at low temperature (near about 0°C).
 - Pasteurization—It is heating of food at high temperature i.e., the microorganisms eliminated from the food.
- 4. (c) Cyanobacteria are also called myxobacteria. In which flagella one completely absent but the movement occurs in some genera by special gliding motion. Such movement are connected with the secretion of mucilage.
- 6. (b) In the classic pasteurization treatment of milk, the milk was exposed to a temperature of about 63°C for 30 minutes. Most milk pasteurization today uses higher temperatures, at least 72°C, but for only 15 seconds.
- (a) Exotoxin is produced by mostly gram positive bacteria, these are protenaceous and heat labile compound which are excreted by bacteria out side the cell.
- (d) The mucopeptide or murein is a polymer of two amino sugars namely N-acetylglucosamine (NAG) and Nacetyl muramic acid (NAM).
- 10. (b) Causing agent of Mycobacterium laprae can not be
- 11. (a) 6CO₂+12H₂S Light → C₀H₁₂O₀+12S+6H₂O + energy. Here H₂S is utilized as a source of hydrogen, which reduces CO₂ into glucose. Oxygen is not liberated in bacterial photosynthesis.
- 12. (c) Salting of pickles, meat, fishes etc. and addition of sugar to jams, jellies, cut fruits etc., prevent their decay by microbes, as the latter get killed due to plasmolysis or due to high concentration of salt or sugar.
- (a) Endospore formation is more common in rod shaped bacteria or bacillus forms.
- (b) Some bacteria damage cellulose of textiles. e.g., Spirochaete cytophage, cellulomonas etc.
- 16. (a) Bacteroid : Symbiotic bacteria Rhizobium leguminosarum in leguminous plants e.g., gram, pea etc. in their roots nodules produce Leg haemoglobin, this whole Bacteria + Leg haemoglobin + Polyploide cells of roots is called as bacteroid.
- 22. (a) Bacterial blight of rice is a seed borne disease which is transmitted to paddy. Seedlings when raised under high humid conditions. This disease is caused by Xanthomonas oryzae.

Characteristics of protista

Protista (*Protistos* = Primary) includes unicellular eukaryotes and show the following characters :

- (1) Protists include solitary unicellular or colonial unicellular eukaryotic organisms which do not form tissues.
- (2) The single cell may be naked or covered by cell wall, pellicle, cuticle or shell.
- (3) Simple multinucleate organisms or stages of life cycles occur in a number of groups.
- (4) The organisms possess double and porous nuclear membranes, mitochondria, golgibody, plastids (in many), vacuoles, lysosomes and ribosomes are also present. Centrosome occur in many cases.
- (5) In many forms, plastids, (9+2 strand) flagella and other organelles are present.
- (6) Some protists possess contractile vacuole for regulation of their water content.
- (7) Their reproductive cycles typically include both asexual divisions of haploid forms and true sexual processes with karyogamy and meiosis.
- (8) The organisms move by flagella or by other means or are non-motile.
- (9) It may be photosynthetic, holotrophic, saprotrophic, parasitic and symbionts. Some have mixotrophic nutrition (holotrophic + saprobic). The photosynthetic, floating protists are collectively called **phytoplankton**. The free-floating, holozoic protozoans are collectively termed **zooplankton**.

- (10) Asexual reproduction is the most common method in protists. It involve binary fission (*Paramecium*, *Euglena*, *Amoeba*), multiple fission (*Amoeba*), plasmotomy (*Opalina*), budding (*Paracineta*, *Arcella*) and spore formation (Slime moulds).
- (11) Sexual reproduction is believed to have originated in primitive protists. It involve isogamy (*Monocystis*), anisogamy (*e.g.*, *Ceratium*) and oogamy (*e.g.*, *Plasmodium*).

Classification of protista : Unicellular protists have been broadly divided into three major groups :

- (i) Photosynthetic protists : e.g., Dinoflagellates, Diatoms, Euglenoids.
 - (ii) Consumer protists: e.g., Slime moulds or Myxomycetes.
- (iii) Protozoan protists : e.g., Zooflagellata, Sarcodina, Sporozoa, Ciliata.

Photosynthetic protists

Dinoflagellates

- (1) This is well defined group of unicellular, golden-brown photosynthetic organisms. Majority of them are motile and flagellated but a few are non-motile and non-flagellated. Flagellated forms exhibit peculiar spinning movement. Hence, they are called whorling whips.
- (2) The cell wall of dinoflagellates, if present, is composed of a number of plates made up of cellulose. It is called **theca** or **lorica**. The theca contains two grooves-longitudinal **sulcus** and transverse **girdle** or **annulus**.
- (3) Usually the cells possess two flagella which are of different types (heterokont).

- (4) Trichocysts are rod like or spindle shaped ejective structures which occur just below the cell membrane.
- (5) Cells possess a relatively large and prominent nucleus known as mesokaryon. DNA is without association with histone.
- (6) There are numerous discoid chloroplasts without pyrenoids. They are yellow-brown to dark-brown in colour due to presence of characteristic **pigments** Chlorophyll a, c, α -carotene and xanthophylls (including dinoxanthin and peridinin).
- (7) The cells possess an osmoregulatory organelle called pusule which superficially looks like contractile vacuole.
- (8) In dinoflagellates it is mainly holophytic or photosynthetic. However, some forms are saprobic, parasitic, symbiotic or holozoic. For example, a colourless *Blastodinium* is parasite on animals.
- (9) Dinoflagellates reproduce asexually through cell division or by the formation of zoospores and cysts. The cell division starts from posterior end. During cell division, centromeres and spindle are not seen.
- (10) If sexual reproduction occurs, is isogamous or anisogamous. Two cells conjugate by a conjugation canal where the two amoeboid gametes fuse to form a diploid zygote. Life cycle involves zygotic meiosis (e.g., Ceratium, Gymnodinium etc.) or gametic meiosis (e.g., Noctiluca).

Examples : Glenodinium, Peridinium, Gymnodinium, Gonyaulax, Ceratium, Noctiluca.

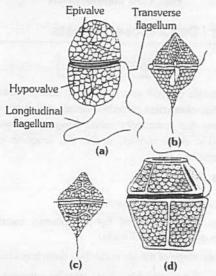

Fig: 1.3-1 Some dinoflagellates (a) Glenodinium (b) Peridinium (c) Gynnodium (d) Gonyaulax

Diatoms

General character

- (1) Most of the diatoms occur as phytoplanktons both in fresh and marine waters. A few forms occur as benthos the bottom of water reservoirs. Diatoms constitute a major part of phytoplankton of the oceans.
- (2) The cells of diatoms are called frustules or shell. They are microscopic, unicellular, photosynthetic organisms of various

- colours and diverse forms. They may be circular, rectangular, triangular, elongated, spindle-shaped, half-moon shaped, boat-shaped or filamentous. Incipient filament occur in *Melosira*.
- (3) They exhibit mainly two types of symmetry-radial symmetry as in **centrales** (e.g., Cyclotella, Biddulphia, Triceratium, Melosira) and isobilateral symmetry as in **Pennales** (e.g., Pinnularia, Synedra, Actinella, Navicula).
- (4) The cell wall is chiefly composed of cellulose impregnated with glass-like silica. It shows sculpturings and ornamentations. It is composed of two overlapping halves (or theca) that fit together like two parts of a soap box. The upper half (lid) is called epitheca and the lower half (case) is called hypotheca.
- (5) Diatoms do not possess flagella except in the reproductive stage. They show gliding type of movement with the help of mucilage secretion. They float freely on the water surface due to presence of light weight lipids.
- (6) Each cell has a large central vacuole in which a prominent nucleus is suspended by means of cytoplasmic strands. The cells are diploid (2N). In case of centrales, the nucleus lies in the peripheral region.
- (7) Some species of diatoms are devoid of chromatophores, e.g., Nitzschia alba. They are saprotrophic in nutrition.
- (8) The reserve food material is **oil** and a polysaccharide **chrysolaminarin** (or **leucosin**).
- (9) Most common method of multiplication is binary fission (cell division) that occurs at night.
- (10) Sexual reproduction takes place by the fusion of gametes. Meiosis is gametic *i.e.*, takes place during the formation of gametes.

Examples: Triceratium, Pleurosigma, Navicula, Cymbella, Amphipleura, Nitzschia, Melosira, Pinnularia.

Euglenoid

- (1) Euglenoids and their non-motile relatives are unicellular flagellate protists.
- (2) These protists are devoid of cellulose cell wall. The body is covered by thin and flexible pellicle. The pellicle has oblique but parallel stripes called myonemes. The pellicle is composed of fibrous elastic protein and small amount of lipid or carbohydrates.
- (3) The euglenoids have two flagella, usually one long and one short. Each flagellum arises from a basal granule (blepharoplast). The flagella bear hair.
- (4) They can undergo creeping through expansion and contraction of body called metaboly.

- (5) The apical end bears an invagination having three parts—cytostome (mouth), cytopharynx (gullet or canal) and reservoir. The cytostome is generally eccentric.
- (6) The two flagella join with each other at a swelling called paraflagellar body. An orange red coloured eye-spot or stigma is located at the base of flagellum attached to the membrane of reservoir at the level of paraflagellar body. They contain red pigment **astaxanthin**. Both paraflagellar body and eye spot act as photoreceptors and direct the organism towards the optimum light.
- (7) An osmoregulatory contractile vacuole occurs in the anterior part of the cell below the reservoir.
- (8) Nutrition is holophytic (photoautotrophic), saprobic (e.g., Rhabdomonas) or holozoic (e.g., Peranema). Even holophytic forms can pick up organic compounds from the outside medium. Such a mode of nutrition is called mixotrophic.
- (9) Product of photosynthesis is paramylon which is stored in the form of paramylum granules in the paramylum bodies in cytoplasm.
- (10) Sexual reproduction has not yet been definitely proved. Under favourable conditions, euglenoids multiply by longitudinal binary fission.
- (11) These protists perennate during unfavourable periods as cysts.

Example : Euglena, Phacus, Eutreptia, Trachelomonas, Peranema.

Euglena

General characters

- (1) Euglena is a connecting link between animals and plants.
- (2) Euglena resembles the ancestral form from which the plants and animals evolved.
- (3) Euglena is a free swimming fresh water flagellate which moves by two different methods:
- (i) Euglenoid movement (wriggling movement), by contraction and expansion of the body.
- (ii) Flagellar movement, with the help of sticonematic type flagellum.
- (4) Body is covered by pellicle, a small cytostome (cell mouth) and cytopharynx is present at the anterior end of the body.
- (5) Euglena contains chlorophyll, yet it resembles animals, because it feeds like animals in the absence of sunlight.
- (6) Nutrition in Euglena is mixotrophic, when light is available it is photosynthetic, in darkness it is saprophytic absorbing food from surrounding water.
- (7) Reserve food is stored in the form of paramylum or paramylon.
- (8) Asexual reproduction occurs by longitudinal binary fission, no sexual reproduction.

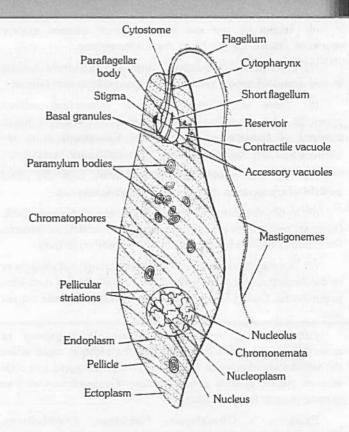

Fig: 1.3-2 Euglena viridis

Consumer / Decomposer protists

Slime moulds

Slime moulds include very interesting and peculiar organisms which share the characters of both animals and fungi. Due to this peculiarity they are commonly called **fungus animals**. Modern biologist include slime moulds under the kingdom-protista and called them protistan fungi.

General characters

- (1) They do not have chlorophyll.
- (2) They are surrounded by the plasma membrane only (somatic parts are without cell walls).
 - (3) At one stage of the life cycle they have amoeboid structure.
- (4) The slime moulds live usually amongst decaying vegetation. They are quite common on lawns and moist fields.
- (5) They have phagotrophic or saprotrophic nutrition. Parasitic forms are not known
- (6) The sporangia produce spores. Each spore possesses a cellulose cell wall.

Acellular (Plasmodial) Slime moulds

- (1) Acellular slime moulds commonly grow as slimy masses on damp places rich in dead and decaying organic matter.
- (2) The somatic phase is diploid and consists of a free living organic matter multinucleated protoplasm called plasmodium.

- (3) The plasmodium slowly streams or glides over decaying organic matter putting out blunt finger like pseudopodia showing amoeboid movement.
- (4) They also absorb dissolved organic substances from the substratum showing saprotrophic nutrition.
- (5) Each plasmodium reproduces asexually by the formation of several, small, sessile or stalked, brightly coloured sporangia.
- (6) When fully mature, the wall of the sporangium bursts to release the spores. The spores are dispersed by air.
- (7) On germination, a spore generally releases one biflagellate, spindle-shaped swarm cell or a non-flagellate myxamoeba. The myxamoebae feed on bacteria and yeasts and multiply in number. The swarm cells swim about actively and finally fuse in pairs at the posterior nonflagellate ends to form zygotes.
- (8) The diploid nucleus of zygote undergoes repeated mitotic divisions. As a result, the zygote gradually changes into a multinucleate amoeboid structure, the plasmodium. The plasmodium repeats the life cycle.

Examples : Physarum, Physarella, Fuligo, Dictydium, Lucogala, Tubifera.

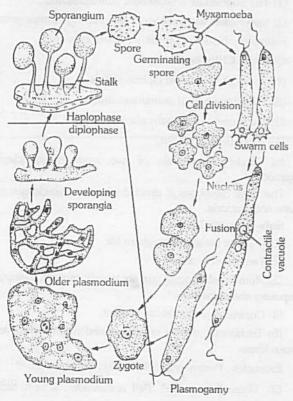

Fig: 1.3-3 Diagramatic life cycle of acellular Slime mould (e.g., Physarum)

Cellular Slime moulds

General characters

- (1) The cellular slime moulds occurs in the form of haploid uninucleated, naked (without cell wall) cell covered by plasma membrane. These cells are called myxamoebae.
- (2) The myxamoebae move freely with the help of amoeboid movement and phagotrophic or holozoic nutrition.

(3) Under unfavourable condition a myxamoeba secrete a rigid cellulose wall to form the microcyst. Microcyst formation is a means of perennation.

The microcysts can be dispersed. On the return of favourable conditions, the microcyst wall ruptures to release a myxamoeba. The latter resumes its function of feeding, growth and multiplication forming amoeboid cells.

- (4) When the food supply is exhausted the amoeboid cells get aggregated without any fusion. The stimulus for the aggergation process is due to release of cyclic 3',5' adenosine monophosphate (cyclic AMP) from the amoeboid cells. This aggregated mass of cells is called pseudoplasmodium. It is a sort of community association. Because of this reason, cellular slime moulds are called the communal slime moulds.
- (5) The stalk of sporocarp may remain upright or bend. Finally the spores are released and disseminated.
- (6) The most important character of cellular slime moulds is the complete absence of flagellated cells in their life cycle.
- (7) The cellular slime moulds resemble plant in having cellulose cell wall in spores and resemble animals in having amoeba-like myxamoebae.

Examples: Dictyostelium, Polysphondylium.

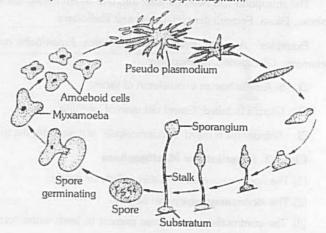

Fig: 1.3-4 Diagramatic life cycle of cellular slime mould Protozoan protists (Gr. *Protos* = first; zoon = animal)

It include all unicellular (or acellular) eukaryotic animals. These are most primitive organisms considered as animals because of heterotrophic nutrition and motility. About 50,000 species (30,000 present and 20,000 extinct) are so far known.

Brief history: Protozoans were first studied by Leeuwenhoek (1677). The name "Protozoa" was coined by Goldfuss (1817). The branch of their study is called Protozoology.

- (1) Protozoans are the simple and primitive organisms.
- (2) They are free living or parasitic.

- (3) They are asymmetrical or radially symmetrical or bilaterally symmetrical.
 - (4) They are unicellular (acellular).
 - (5) They have protoplasmic grade of organization.
 - (6) Locomotion is effected by flagella, cilia or pseudopodia.
 - (7) Nutrition is holophytic, holozoic, saprozoic or parasitic.
 - (8) Digestion is intracellular.
 - (9) Excretion and respiration occurs by diffusion.
- (10) In fresh water protozoans osmoregulation is carried out by the contractile vacuoles.
 - (11) Reproduction occurs by asexual and sexual methods.

Classification of Protozoans

Protozoans are classified on the basis of locomotory organelles into following classes.

Class 1. Rhizopoda or Sarcodina

- (1) There is no definite cell wall or pellicle.
- (2) There is no definite shape.
- (3) The locomotory organs are pseudopodia.
- (4) There is no permanent mouth or anus.
- (5) The contractile vacuoles are present in the fresh water forms.

The rhizopoda has been divided into five orders. They are as Lobosa, Filosa, Foraminifera, Heliozoa and Radiolaria.

Examples : Amoeba, Entamoeba histolytica, Entamoeba coli, Pelomyxa, Globigerina, Actinophryx.

- ☐ In Arcella has an exoskeleton of tactin.
- ☐ Giardia is called 'Grand old man of intestine'.
- ☐ Actinophryx is called 'Sun animalcule' as it resemble the sun.

Class 2. Flagellata or Mastigophora

- (1) The body is covered by a thin pellicle or cuticle.
- (2) The locomotory organs are flagella.
- (3) The contractile vacuoles are present in fresh water forms with accessory vacuoles.
 - (4) Chloroplast are found in some forms.
 - (5) They may be free living or parasitic.

The class flagellata has been divided into eight orders. They are as Chrysomonadina, Cryptomonadina, Euglenoidea, Phytomonadina, Dinoflagellata, Cystoflagellata, Protomonadina and Polymastigina.

Examples : Chrysamoeba, Cryptomonas, Volvox, Chlamydomonas, Noctiluca, Mastigamoeba, Monal, Bado, Trypanosoma, Leishmania, Proterospongia etc.

- ☐ Trychonymph (symbiotic) live in alimentary canal of termite that is digest to cellulose.
- ☐ Noctiluca shows bioluminiscense due to luciferin protein. It is also called the 'Fire of sea'.

Class 3. Sporozoa

- (1) They are exclusively endoparasitic.
- (2) The body is covered by pellicle.
- (3) Reproduction takes place by spore formation.

The class is divided into two sub-classes, namely, Telosporidia and Neosporidia.

Sub-class (i) Telosporidia

- (1) The spores do not contain polar capsules or filaments.
- (2) The life history ends with the formation of spores.
- (3) The spore cases are simple and contain many spores.

Examples : Monocystis, Gregarina, Isopora, Eimeria, Plasmodium, Babesia etc.

- ☐ Babesia causes the 'Taxas cattle fever' in animals. This disease also called 'Red water fever' or Haemoglobin uric fever.
- Monocystis is found in seminal vesicle of earthworm, and causes sterlity in earthworm. It is monogenetic in nature.
 - ☐ Eimeria is found in epithelial cells of liver of Rabbit.

Sub class (ii) Neosporidia

- (1) The trophozoite is amoeboid multinucleated.
- (2) Spore cases are complex usually having a single germ.

Examples: Nosema, Myxidium, Globidium etc.

Class 4. Ciliophora

- (1) The body is covered by thin pellicle.
- (2) They have a fixed permanent shape.
- (3) The locomotory organs are cilia.
- (4) Tentacles are present.
- (5) Nuclei are usually of two kinds micronucleus and meganucleus.

The class ciliophora is divided into two sub-classes, namely Ciliata and Suctoria.

Sub-class (i) Ciliata

- (1) Cilia are present throughout life.
- (2) Tentacles are absent.
- (3) Mouth and cytopharynx are usually present. Cytopyge is a temporary anal apperture.
 - (4) Contractile vacuoles are present.
- (5) Trichocysts, organs of offense and defence are present in certain forms.

Examples: Paramecium, Stylonchia Vorticella etc.

- $\ \ \square$ Vorticella is called 'Bell animalcule'. It is a pedicellate protozoan.
- ☐ Nyctotherus is a parasite in the rectum of frog. It is also found in the rectum of cockroach.

Sub-class (ii) Suctoria

- (1) Cilia are present only in the young conditions and adults are devoid of them.
 - (2) Tentacles are present in the adult.
 - (3) One to many contractile vaculoes are present.

Examples: Acineta, Ephelota, Dendrocometes, Dendrosoma etc.

Some representative protozoan protists

Amoeba proteus

- Amoeba belongs to the class Sarcodina or Rhizopoda of the phylum protozoa. It is discovered by Russel Von Rosenhoff in 1755.
- (2) The most common species is Amoeba proteus. Proteus is the name of the mythical sea god who could change shape.
 - (3) Amoeba is cultured in laboratory by Hay infusion method.
- (4) Body is covered by plasmalemma. It is a trilaminar and selectively permeable membrane. Plasmalemma is excretory, ammonia diffuses out through it. It is also respiratory diffusion of oxygen and carbon dioxide takes place through it.
- (5) The body bears a number of temporary and blunt pseudopodia. The type of pseudopodium found in Amoeba proteus is lobopodium. Pseudopodia are composed of both ectoplasm and endoplasm.
- (6) Pseudopodium at its forward end gets its firm consistency by hyaline cap which is made of ectoplasm.
- (7) Pseudopodia in Amoeba are meant for feeding and locomotion.
- (8) Pseudopodia are found in Amoeba and leucocyte of higher animals.
- (9) Cytoplasm is differentiated into outer ectoplasm and inner endoplasm. Endoplasm is divided into outer plasma gel and inner plasma sol.
- (10) Locomotion of *Amoeba* is known as amoeboid movement. Sol gel theory of amoeboid movement was first given by Hyman supported by Pantin and Mast. According to this theory amoeboid locomotion is due to change in the viscosity of cytoplasm. This is the most accepted theory.

Table: 1.3-1 Theories of Amoeboid Movement

Surface tension theory	Berthold	(1886)
Rolling movement theory	Jennings	(1904)
Walking movement theory	Dellinger	(1906)
Sol-gel theory	Hyman	(1917)
Folding and unfolding theory	Goldacre and Lorch	(1950)
Contraction-hydraulic theory	Rinaldi and Jahn	(1963)

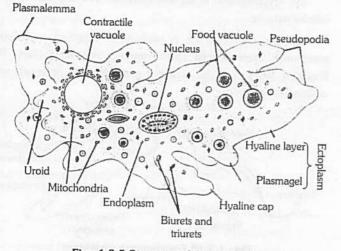

Fig: 1.3-5 Structure of Amoeba proteus

- (11) Sol gel conditions are due to contraction and relaxation of long chains of proteins.
- (12) Amoeba contains a nucleus, a contractile vacuole, a number of food vacuoles and other cell organelles.
- (13) Vacuole is found only in fresh water forms. It is absent in marine and parasitic forms.
- (14) If an Amoeba is placed in distilled water its contractile vacuole works faster while in salt water, its contractile vacuole will disappear.
- (15) Contractile vacuole of Amoeba is analogous (similar in function) to uriniferous tubules of frog.
- (16) Food of Amoeba consists of bacteria, diatoms, small protozoa and algae.
- (17) The process of ingesting solid food is phagocytosis, Amoeba ingest food by import, circumfluence, circumvallation and invagination.
- (18) Import involves passive sinking of food into body by rupture of plasmalemma, e.g., Ingestion of algae.
- (19) Circumfluence is the ingestion of less active or motionless organisms like bacteria.
- (20) Circumvallation is the engulfment of active prey like ciliate or flagellate. In this way a food cup is formed containing the organism.
- (21) Digestion in Amoeba is intracellular. Amoeba secretes digestive enzymes for hydrolysing starch, protein, fat etc.
- (22) Food vacuole of *Amoeba* is analogous to the alimentary canal of an animal or gastro vascular cavity of *Hydra*. The contents of food vacuole in *Amoeba* first becomes acidic then alkaline.
- (23) Amoeba responds to environmental conditions. Response to the stimuli is called taxis. Different taxis are thermotaxis (temperature) phototaxis (light), thigmotaxis (touch), chemotaxis (chemicals), galvanotaxis (electric current), geotaxis (gravity) and rheotaxis (water current).
- (24) Normal method of asexual reproduction is binary fission. Binary fission is a process of mitosis. It takes place when food is abundant and temperature is suitable.
- (25) Multiple fission or sporulation takes place during unfavorable conditions after encystment. There are three layers of cysts.
 - (26) Amoeba regenerates from nucleated bits.

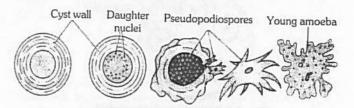

Fig: 1.3-6 Encystment and multiple fission in Amoeba

Pseudopodia: These are found in those forms which do not possess a definite pellicle. According to size, structure, and shape pseudopodia may be of different types as:

Lobopods: These are short, blunt and thick finger like out growth of ectoplasm with an axial core of endoplasm *e.g.*, *Amoeba*, *Arcella* etc.

Filopods: They are cylindrical thread like, formed entirely of ectoplasm and radiate from the body in all directions e.g., Euglypha, Radiolaria.

Reticulopods: They are filamentous which form a network of pods e.g., Polystomella, Chlamydophrys.

Axopods: These are long stiff semi-transparent extensions of cytoplasm with pointed distal ends e.g., Actinophrys.

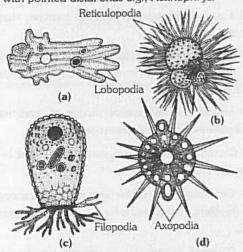

Fig: 1.3-7 Structure of Lobo, Filo, Reticulo and Axopods

Entamoeba histolytica

General characters

- (1) Entamoeba histolytica is a monogenetic parasitic and pathogenic protozoan protists which resides in the upper part of large intestine in human beings. It causes amoebic dysentery or amoebiasis.
- (2) Lamble (1859) discovered E. histolytica. Friedrick Losch, a Russian Zoologist, discovered its pathogenic nature in 1875.
- (3) It has two forms, adult trophozoite or magna, pathogenic form found in the mucosa and sub-mucosa of intestine forming ulcers and minuta, nonpathogenic form found in the lumen of intestine.
 - (4) Entamoeba has no contractile vacuole.
- (5) Trophozoite of *Entamoeba* reproduces by binary fission. Minuta form encysts. A mature cyst is called quadrinucleate cyst. It has four nuclei and two chromatoid bodies.

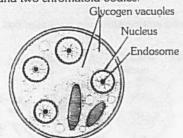

Fig: 1.3-8 Quadrinucleate cyst of Entamoeba histolytica

- (6) Quadrinucleate cyst is the infective stage. Infection is oral through contaminated food and water.
- (7) The reserve food material in cyst of E. histolytica is glycogen. A single cyst of E. histolytica produces eight amoebulae.
- (8) It damages instestinal mucosa by secreting an enzymehistolysin.
 - (9) It completes its entire life-cycle in one host only; Man.

Entamoeba gingivalis

Entamoeba gingivalis is a parasite of human teeth, found in the abscesses of gum and in pus pockets of pyorrhoea, bleeding gums. It increase pyorrhoea disease but does not cause it. Pyorrhoea is caused by *Trichomonastinax*. Adult is called trophozoite and has 2-3 pseudopodia. It feeds on WBCs, bacteria and pus cells. Cyst is not formed in E. Gingivalis and infection occurs by direct contact like kissing.

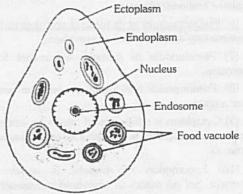

Fig: 1.3-9 Entamoeba gingivalis

Trypanosoma gambiense

- (1) Trypanosoma gambiense is the parasite zooflagellate which causes one of the deadliest ailments in human beings called African sleeping sickness or Trypanosomiasis. It was discovered by Frode in 1901.
- (2) Trypanosoma is usually found in the blood of vertebrates, finally invading cerebrospinal fluid.
- (3) Trypanosoma is an endoparasite, blood parasite, extra cellular parasite.
- (4) Trypanosoma has a nucleus, a flagellum, undulating membrane, blepharoplast (basal granule) and kinetoplast. The flagellum arises from the posterior end and runs anteriorly with undulating membrane.

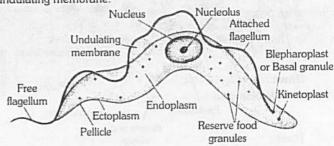

Fig: 1.3-10 Trypanosoma gambiense

- (5) Trypanosoma reproduces asexually by longitudinal binary fission. It does not form cysts.
- (6) Trypanosoma is polymorphic and has four forms: Leishmania, Leptomonad, Crithidial and Trypanosomal (= Metacyclic) stages.
- (7) Trypanosoma is digenetic, it completes its life cycle in two hosts. The primary or principal or definite host is man and the intermediate or secondary host or vector is the insect, tse-tse fly or bug.
- (8) Three important species of *Trypanosoma* for which man is host are: *Trypanosoma gambiense*, *T. rhodesiensi* and *T. cruzi*.
- (9) The chief vector host of *T. gambiense* transmitting the disease from one man to another is the tse-tse fly, *Glossina* palpalis. Occasionally, *Glossina* tachinoides also act as a vector.
- (10) T. rhodesiensi causes Rhodesian trypanosomiasis, it is confined to east central parts of Africa, particularly Rhodesia. The insect vectors for T. rhodesiense are tse-tse flies mainly Glossina morsitans and G. pallidipes.
- (11) T. cruzi is the causative agent of South American trypanosomiasis or Chaga's disease T. cruzi is transmitted by bugs like Triatoma and Panstrongylus. Symptoms of Chaga's disease are fever, diarrhoea, anaemia and enlargement of lymphoid glands etc.

Plasmodium vivax

They are spore forming parasitic protists which lack locomotory structure and contractile vacuoles. The body is covered by pellicle or cuticle.

Systematic position

Phylum – Protozoa

Sub-phylum – Plasmodroma

Class – Sporozoa

Sub-class – Telosporidia

Order – Haemosporidia

Genus – Plasmodium

species – vivax

History: The term malaria was coined by Mucculoch in 1827.

Lancisi first suspected a relationship between malaria and mosquito.

Laveran (1880) discovered that malaria is caused by a protozoan parasite, *Plasmodium vivax*.

Sir Ronald Ross was (1896) the first to observe oocytes of Plasmodium in female Anopheles.

Grassi and Feletti (1898) was the first to describe the life cycle of *Plasmodium* in *Anopheles*.

Golgi (1885) Studied erythrocytic cycle of plasmodium.

Host: It is digenetic i.e., life cycle is completed in two hosts -

(1) Man (medically primary but biologically secondary host)

(2) Female Anopheles (medically secondary but biologically primary host).

Life cycle: During life cycle two important phases are present.

- (1) Endogenous or Asexual phase: passes in man.
- (2) Exogenous or Sexual phase : passes in female Anopheles mosquito.

In Man (Schizogony)

Infective stage: It is spindle shaped sporozoite introduced by female *Anopheles* along with saliva (for anticoagulant anophilin) during blood sucking. Sporozoite enters liver cells. In liver they produce several stages.

Pre-erythrocytic stage: Each sporozoite enters inside the liver cell and becomes spherical and termed as cryptozoite. It undergoes a pre-erythrocytic cycle completed in 10 days and multiplies asexually by schizogony. After rupturing schizont numerous cryptomerozoites are liberated.

Exo-erythrocytic stage: Cryptomerozoites enter in new liver cells and reproduce asexually to give rise to a large number of meta-cryptomerozoites, few are smaller in size and called micrometacryptomerozoites.

Erythrocytic stage: Micro metacryptomerozoites enter into the blood stream and each enters the RBCs and assumes rounded disc like shape with single nucleus. It develops a vacuole which gives a ring like appearance. This stage is known as signet ring stage. During further development the vacuole is lost and parasite feeds on the cytoplasm of R.B.C. This stage is known as amoeboid stage or trophozoite stage. The matured trophozoite develops to become a schizont. It multiplies asexually by erythrocytic schizogony.

Formation of gametes : Some merozoites do not enter schizogony but instead form gametocytes in RBCs. Gametocytes are of two types :

- Macro-gametocytes: These are female cells which are large in size, laden with food material and having nucleus at one end.
- (2) Micro-gametocytes: These are male cells, small in structure and nucleus placed centrally.

In Mosquito (Sporogony)

When female Anopheles bites a patient of malaria, the parasites enter the alimentary canal of the insect. In the stomach of mosquito the asexual forms are digested and only gametocytes survive. Gametocytes are released in blood plasma in large numbers during mid night. They die by morning. Megagametocyte produces only one megagamete. Microgametocyte produces 4-8 motile microgametes by exflagelation.

Fertilization : Both mega and microgamete fuse, form zygote which narrows to becomes ookinete. Ookinete pierces the stomach wall and forms a cyst on its outer surface.

Sporogony: Oocyst undergoes a process of sporogony. The irregular cells thus formed are known as sporoblasts. The nucleus of sporoblast divides several times to give rise to daughter nuclei which migrate in the projections of sporoblast.

These minute projections change into the form of sporozoites. After maturity oocyst burst out and numerous sporozoites are liberated into the body cavity of mosquito. The sporozoites move towards salivary glands and bore into them. In this way they are ready for transmission.

Control of malaria

- (1) Prevention from infection is called prophylaxis.
- (2) Quinine is obtained from bark of Cinchona (discovered in Peru) which is most commonly used against malaria.
- (3) Peludrine, atabrine, camoquinine, Chloroquinine are few other drugs effective against malaria.
- (4) G.B.P. is General Blood Picture i.e., blood film made for the test of malaria.
- (5) Spraying of oil upon stagnant water controls malaria because larva cannot breath and die.
- (6) Gambusia (Mosquito fish) feeds on larvae and pupa of mosquito. This fish is used in biological control of mosquito.

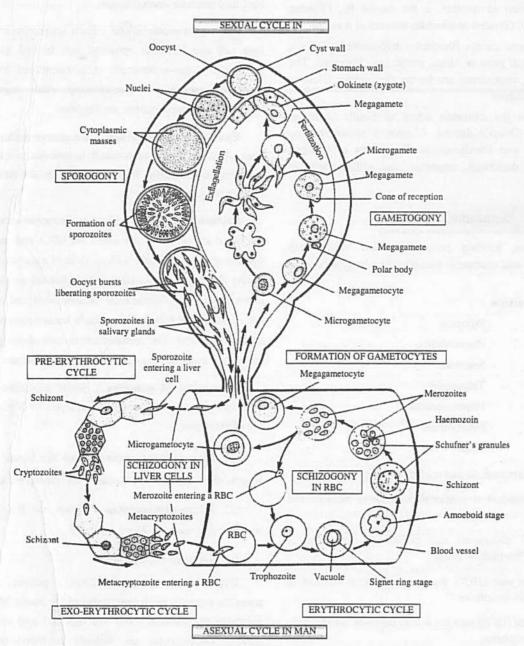

Fig: 1.3-11 Life cycle of Plasmodium vivax

Table: 1.3-2

Name	P. vivax	P. malariae	P.ovale	P. falciparum	
RBC of 1 man 1 2 Distribution Tropical countries of		Liver and RBC of man	Liver and RBC of man	Liver and RBC of man Tropical countries	
		Tropical countries subtropical	West Africa and South America		
Duration of exoerythrocy tic cycle or prepatent period	8 days	14-15 days	9 days	5 days	
Duration of erythrocytic cycle	48 hours	72 hours	48 hours	48 hours	
5. Incubation period	12-14 days	20-24 days	14 days	12 days	
6. Duration of sexual cycle	10 days	26-28 days	16 days	10-12 days	
7. Disease (Type of malaria fever)	Benign and tertian malaria / relapse malaria	Quartan malaria clinical malaria	Ovale and tertian recuris every third day	Malignant tertian malaria Pernicious malaria Estivoautmnal malaria	
8. Pigment and color	Schuffner's granules Yellow / brown	Zeiman's dot Dark brown	Schuffner's dots Dark brown	Maurer's dots Dark green	

Paramecium

- Paramecium is a holotrichous ciliate protozoan. It is discovered by Hill in 1752.
- (2) Paramecium is free-living and aquatic form. In laboratory, Paramecium is cultured by 'Hay-infusion method'.
- (3) Paramecium is commonly called as 'Slipper animalcule'. Body is distinguished into an oral or ventral surface and an aboral or dorsal surface.
- (4) Body is covered with a thin, firm, flexible membrane called pellicle. Entire body surface is covered by numerous cilia, the locomotory organelles. Cilia in the posterior end are longer called caudal tuft. Each cilium arises from a basal granule or kinetosome. Paramecium has infraciliary and neuromotor system to co-ordinate ciliary beat.
- (5) Trichocysts are peculiar bottle-shaped organelles present in the ectoplasm of *Paramecium*. Trichocysts are the organelles of offence and defence.
- (6) Paramecium is heterokaryotic (dimorphic nuclei) i.e., macronucleus and micronucleus. Macronucleus is one, large, kidney shaped, controls vegetative functions (metabolism). Micronuclei, one (P. caudatum), two (P aurelia) and several (P. multimicronucleatum) are only concerned with reproduction.

- (7) Oral apparatus consists of cytopharynx and cytostome (mouth), cytopyge or cytoproct (anus). Nutrition or food intake in paramecium is holozoic. Paramecium is a filter feeder and feeds on small protozoa, unicellular plants (algae), diatoms, yeast etc. and small bits of animals and vegetables. Most favourite food is Tetrahymena, another ciliate protozoa.
- (8) Digestion in paramecium is intracellular. Food vacuole constantly moves along a definite courses (cyclosis) within streaming endoplasm. Food vacuole is digested in the cell body in acidic to alkaline media. Egestion of undigested food takes place through cytopyge or cytoproct, a temporary formed anus.
- (9) Paramecium reproduces by transverse binary fission and nuclear reorganisation. Binary fission occurs during favourable condition. In this process, macronucleus divides amitotically and micronucleus mitotically.
- (10) Paramecium undergoes several kinds of nuclear reorganisation such as conjugation, autogamy, cytogamy, endomixis and hemimixis. Nuclear reorganisation takes place for rejuvenation.
- (11) Conjugation occurs between two mating types of same species of *Paramecium*. It is a modified form of cross fertilization. Each conjugant produces a female stationary and a male migratory nucleus by three successive divisions of micronucleus. They are called pronuclei.
- (12) Synkaryon is the diploid nucleus formed by the fusion of stationary and migratory nuclei in conjugant. Synkaryon divides thrice to form eight nuclei. At the end of the conjugation each *Paramecium* (exconjugant) produces four daughter Paramecia.
- (13) Autogamy is a process of self fertilization. It occurs in a single animal of P. aurelia. Autogamy results in the production of two daughter paramecia from each.

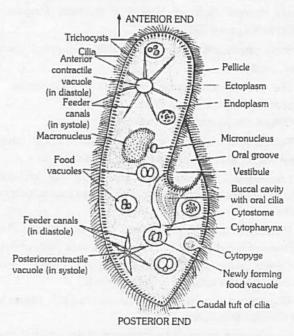

Fig: 1.3-12 Paramecium caudatum

- (14) Cytogamy occurs in *P.caudatum*. The two cytogamonts do not exchange their male pronuclei. Endomixis occurs in *P.aurelia*. It is an asexual reproduction and one individual produces four daughter paramecia. Hemimixis is the process of purification act on the part of meganucleus.
- (15) Paramecium has kappa, Lambda, Mu and Pi particles in cytoplasm. They differentiate paramecia between sensitive and killer forms.

Tips & Tricks

- Dinoflagellates with bioluminescence/phosphorescence due to light producing protein luciferin are called **fire algae**. e.g., Noctiluca, Pyrocystis, Pyrodinium etc. Noctiluca is also called 'night light'.
- Dinoflagellates symbionts in other protists and invertebrates are called zooxanthellae.
- ✓ Some dinoflagellates produce red tides of oceans. e.g.,

 Gonyaulax, Gymnodinium etc.
- The siliceous frustules of diatoms do not decay easily. They pile up at the bottom of water reservoirs and form big heaps called diatomite or diatomaceous earth. Diatomite is porous and chemically inert.
- 29th August is celebrated as the 'mosquito day' because Sir Ronald Ross established mosquito malaria relationship on August 29, 1897. He got Nobel prize in 1902.
- Some protozoans have a loose exoskeleton called "Lorica hourse" on them.
- The fastest reproducing protozoan is 'Glaucoma'. It produces 6-generation within 24 hrs.
- & Oblique binary fission in Ceratium.
- Polystomella is dimorphic rhizopod which shows metagenesis or alternation of generation in its life cycle.
- Leishmania is an intracellular parasite of man and other mammals. It causes Leishmaniasis. L. donovani causes Kala-azar in man.
- Proterospongia is a fresh water colonial and free living flagellate and is connecting link between protozoa and porifera.
- Certain protozoan like Colonympha and Trichonymphya help in digestion of cellulose in certain insects.
- Flagellates are more simplest protozoan while ciliates are most complex protozoans.
- E. coli found as an endocommensal in the colon of about 50% population. It is non-pathogenic.

Ordinary Thinking

Objective Questions

Photosynthetic and consumer protists

- Nutrition in protists is
- [AFMC 2008]
- (a) Holophytic
- (b) Holozoic
- (c) Saprozoic
- (d) All of these
- 2. Which of the following is a slime mould [CBSE PMT 2007]
 - (a) Rhizopus
- (b) Physarum
- (c) Thiobacillus
- (d) Anabaena
- The thalloid body of a slime mould (Myxomycetes) is known as [CBSE PMT 2006]
 - (a) Fruiting body
- (b) Mycelium
- (c) Protonema
- (d) Plasmodium
- 4. Which of the following are the characters of dinoflagellates
 - A. Planktonic golden yellow algae with soap box like structure
 - B. Marine red biflagellated protista
 - C. Appear yellow, green, brown, blue and red in colour
 - D. Biflagellated organisms with pellicle
 - E. Saprophytic (or) parasitic unicellular forms

[Kerala PMT 2012]

- (a) A, B and C only
- (b) B, D and E only
- (c) B and C only
- (d) B and E only
- (e) C, D and E only
- 5. Planktons are organisms which
 - (a) Float on water surface
- (b) Are free swimmers
- (c) Are deep sea forms
- (d) Are burrowing forms
- 6. If phytoplanktons are destroyed in the sea, then
 - (a) No effect will be seen
 - (b) Primary consumers will grow luxuriently
 - (c) It will affect the food chain
 - (d) Algae will get more space to grow
- 7. Which one of the following is a saprophytic protist

[NCERT; Kerala PMT 2012]

- (a) Desmid
- (b) Slime mould
- (c) Euglena
- (d) Gonyaulax
- (e) Nostoc
- Slime moulds in the division Myxomycota (true slime moulds) have [AFMC 2006]
 - (a) Pseudoplasmodia
 - (b) Spores that develop into free living amoeboid cells
 - (c) Spores that develop into flagellated gametes
 - (d) Feeding stages consisting of solitary individual cells
- 9. Auxospores and hormocysts are formed respectively by

[CBSE PMT 2005; AIIMS 2007]

- (a) Some cyanobacteria and many diatoms
- (b) Several cyanobacteria and several diatoms
- (c) Some diatoms and several cyanobacteria
- (d) Several diatoms and a few cyanobacteria

Protista (Unicellular eukaryotes) 65 10. Flagellum of Astasia/Euglena is [APMEE 2002] Euglena is a [CPMT 1998] (a) Pantonematic (b) Acronematic (a) Ciliate (b) Sporozoan (c) Pantachronematic (d) Stichonematic (c) Flagellate (d) Sarcodine 11. The slime moulds are characterized by the presence of Protozoans are able to live efficiently due to their 24. [MH CET 2003; BHU 2004] [AMU (Med.) 1999] (a) Elaters (b) Pseudoelaters (a) Motility (c) Capillitium (d) Capitulum (b) Rapid reproduction 12. Diatoms are [BHU 2000] (c) Ability to manufacture food (a) Fungi Plantae (c) Protista Protozoans (d) Specialised organelles (d) 13. Red oceanic tides can be due to Characteristic spores of diatoms are (a) Diatoms (b) Dinophyceae [KCET 1999; Kerala PMT 1999] (c) Red algae (d) Blue-green algae (a) Ascospores (b) Basidiospores Murein is not found in the cell wall of [KCET 2004] (c) Auxospores (d) Zoospores (a) Nostoc (b) Eubacteria 26. Unlike other algae, diatoms do not readily decay due to (c) Cyanobacteria (d) Diatoms [NCERT; BHU 1999] 15. Slime moulds belong to (a) Siliceous wall (a) Fungi (b) Protista (b) Mucilaginous wall (c) Monera (d) Plantae (c) Water proof cell wall 16. Spore producing body of a cellular slime mould is (d) Nonliving cells (a) Pseudoplasmodium (b) Plasmodium Which one of the following can photosynthesise its food (c) Sporangium (d) Sporophore [JIPMER 1997; KCET 1999; CPMT 2003; VITEEE 2008] Tranverse groove present in dinoflagellates is (a) Hydra (b) Paramecium (a) Sulcus (b) Cingulum (c) Monocustis (c) Annulus (d) Euglena (d) Both (b) and (c) 18. Protistan genome has [CBSE PMT 1994] Sexual reproduction in protists with diploid chromosomes (a) Membrane bound nucleoproteins embedded in [RPMT 1999; Chd. CET 2000] cytoplasm (a) Cyst formation (b) Zygotic meiosis (b) Free nucleic acid aggregates (c) Gametangial meiosis (d) Binary fission (c) Gene containing nucleoproteins condensed together in 29. Diatom frustule/shell is made of loose mass [NCERT; BHU 1998; Manipal 2001] (d) Nucleoprotein in direct contact with cell substance (a) Silica (b) Lime Which protist reproduces both by binary fission and (c) Magnesium carbonate (d) Calcium conjugation Which one of the following is a unicellular, nonmotile 30. (a) Amoeba (b) Paramecium desmid [KCET 2010] (c) Euglena (d) Monocystis (a) Chlorobium (b) Clostridium 20. Protists obtain food as [CBSE PMT 1994] (c) Chromatium (d) Cosmarium (a) Photosynthesisers, symbionts and holotrophs 31. Protista contains [Odisha JEE 2002] (b) Photosynthesisers (a) Euglena, Dinoflagellates and Yeast (c) Chemosynthesisers (b) Amoeba, Paramaecium, Hydra (d) Holotrophs Which one is not a protozoan protist 21. (c) Euglena, Paramaecium, Mushroom [Manipal 1995] (a) Plasmodium vivax (d) Amoeba, Paramaecium and Dinoflagellates (b) Paramecium caudatum 32. Ceratium is [APMEE 2002] (c) Enterobius vermicularis (a) Dinoflagellate (b) Diatom (d) Trypanosoma gambiense (c) Slime mould (d) Sporozoan 22. Which of the following animal is having longitudinal binary Protozoan protists fission [Kerala PMT 2007] (a) Euglena (b) Plasmodium The class of phylum protozoa to which 'Noctiluca' belongs, is (c) Planaria (d) Paramecium (a) Rhizopoda (b) Sporozoa

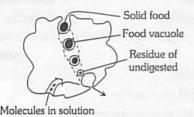

(c) Mastigophora

(d) Ciliata

(e) Hydra

In the diagram, which of the following processes are shown in Amoeba

[KCET 2007]

- (a) Exocytosis
- (b) Phagocytosis
- (c) Pinocytosis
- (d) All of these
- 3. Slimy mass of protoplasm with many nuclei and an Amoeba like thalloid body is a characteristic feature of

[NCERT; Kerala PMT 2009]

- (a) Ascomycetes
- (b) Actinomycetes
- (c) Phycomycetes
- (d) Basidiomycetes
- (e) Myxomycetes
- 4. The class of Trichonympha is

[MP PMT 2000]

- (a) Calcaria
- (b) Scyphozoa
- (c) Sporozoa
- (d) Mastigophora
- The infection of Entamoeba histolytica takes place by

ICPMT 20091

- (a) Trophozoite
- (b) Binucleated cyst
- (c) Trinucleated cyst
- (d) Quadrinucleated cyst
- 6. Paramecium is a
- [Odisha JEE 2008]

- (a) Protozoan
- (b) Bacterium
- (c) Virus
- (d) Annelid
- Which is not the locomotory organ of protozoa

[AFMC 2003, 05; MP PMT 2003]

- (a) Cilia
- (b) Flagella
- (c) Pseudopodia
- (d) Parapodia
- Monocystis belongs to the order
 - [MP PMT 2002]
- (a) Gregarinida
- (b) Coccidia
- (c) Microsporidia
- (d) Sarcosporidia
- Which protozoan is unlikely to have a contractile vacuole

[BHU 2001; CBSE PMT 2001]

- (a) Euglena
- (b) Paramecium
- (c) Amoeba
- (d) Plasmodium
- Entamoeba histolytica is a human parasite usually found in [KCET 1999]
 - (a) Liver
- (b) Lung
- (c) Mouth
- (d) Intestine
- The protozoan parasite which possesses a food vacuole is [EAMCET 1998]
 - (a) Leptomonas
- (b) Plasmodium
- (c) Trypanosoma
- (d) Leishmania
- 12. Which one of the following pairs is correctly matched

[RPMT 2005]

- (a) Aedes plague
- (b) Anopheles malaria

- (c) House fly yellow fever (d) Body louse typhoid
- Total parasites belong to protozoan group

[CPMT 2001, 09; BHU 2002]

- (a) Sporozoa
- (b) Ciliata
- (c) Sarcodina
- (d) Zooflagellata

- 14. Which of the following classes of protozoa is exclusively endoparasite [CPMT 1998]
 - (a) Mastigophora
- (b) Sarcodina
- (c) Opalinata
- (d) Sporozoa
- Match the following and choose the correct combination from the options given

Column I (Group Protista)		Column II (Example)	
A.	Chrysophytes	i.	Paramecium
B.	Dinoflagellates	ii.	Euglena
C.	Euglenoids	iii.	Gonyaulax
D.	Protozoans	iv.	Diatoms

[NCERT; Kerala PMT 2008; AMU (Med.) 2012]

- (a) A-i, B-iii, C-ii, D-iv
- (b) A-ii, B-iv, C-iii, D-i
- (c) A-iv, B-ii, C-iii, D-i
- (d) A iii, B iv, C i, D ii
- (e) A-iv, B-iii, C-ii, D-i
- Which is not true for Paramecium 16.

[Odisha JEE 2009]

- (a) Under unfavourable conditions, form cysts
 - (b) Presence of large number of cilia on whole body surface
 - (c) Contain contractile vacuoles for osmoregulation
 - (d) Use pseudopodia for capturing prey
- 17. Which of the following combination of characters is true of slime moulds **IDUMET 20091**
 - (a) Parasitic, Plasmodium with true walls, spores dispersed by air currents
 - (b) Saprophytic, Plasmodium without walls, dispersed by water
 - (c) Parasitic, Plasmodium without walls, spores dispersed by water
 - (d) Saprophytic, Plasmodium without walls. spores dispersed by air currents
- Slipper animalcule is 18.
- [Manipal 2005]
- (a) Paramecium
- (b) Trypanosoma
- (c) Entamoeba
- (d) Protozoa
- In life cycle of Plasmodium, exflagellation is seen in
 - [CPMT 2005]

- (a) Microgametocytes
- (b) Trophozoites
- (c) Macrogametocytes
- (d) Merozoites [AFMC 2005]
- 20. Man in the life cycle of Plasmodium is (a) Primary host
 - (b) Secondary host
 - (c) Intermediate host
- (d) None of these
- Which of the following unicellular organism has a macronucleus for trophic function and one or more micronuclei for reproduction

[AMU (Med.) 2005; CBSE PMT 2005]

- (a) Euglena
- (b) Amoeba
- (c) Paramecium
- (d) Trypanosoma
- 22. Pseudopodia is a characteristic feature of which class
 - (a) Mastigophora
- (b) Sarcodina

(d) Ciliata

- (c) Sporozoa
- Animals of class ciliata (a) Have two nuclei
- (b) Are autotrophs
- (c) Reproduce sexually
- (d) Possess cilia

Protista (Unicellular eukaryotes) 67 INIVERSAL BOOK DEPOT 1960 Excretion in Amoeba occurs through [CPMT 1999] 38. Which one show bioluminiscence [BHU 2003] (a) Nucleus (b) Parapodia (a) Noctiluca (b) Polystomella (c) Plasmalemma (d) Contractile vacuole (c) Entamoeba (d) Suctoria 25. The reason of pseudopodium formation is [RPMT 1999] 39. Protists are (a) Chemical changes 1. Unicellular and prokaryote (b) Difference in the viscosity Unicellular and eukaryote (c) Difference in the pressure Multicellular and eukaryote (d) Change in the temperature Autotroph and heterotroph Who discovered malaria parasite [CPMT 1996; RPMT 1999] [BHU 2003] (a) Sir Ronald Ross (b) Charles Laveran (a) 1+2+3(b) 2 + 3 + 4(c) Patrick Manson (d) Grassi (c) 3+4(d) 2+4Sporogony of malarial parasite occurs in **IAPMEE 1996:** 40. Locomotory organ of sporozoa is [Bihar MDAT 1995] BHU 1996, 2002; AIIMS 1999; DPMT 2004] (a) Tentacles (b) Reticulocytes (a) Liver of man (c) Legs (d) None of the above (b) RBCs of man 41. Paramecium ingests food through [CMC 2002] (c) Stomach wall of mosquito (a) Cytoproct (b) Cytopyge (d) Salivary glands of mosquito (c) Cytopharynx (d) Cytostome 28. Which of the following is not true for nutrition in Amoeba 42. When a fresh-water protozoan possessing a contractile [Odisha JEE 2005] vacuole, is placed in a glass containing marine water, the (a) Photoheterotrophic (b) Phagocytosis vacuole will [CPMT 1993; DPMT 2001; (c) Intracellular (d) Holozoic CBSE PMT 2004; KCET 2010, 11] 29. Which is filter feeder [MP PMT 1995] (a) Increase in size (b) Decrease in size (a) Amoeba (b) Leech (c) Increase in number (d) Disappear (c) Spider (d) Paramecium 43. Which is false for nutrition in Amoeba [Odisha JEE 2004] 30. Sexual mode of reproduction in protozoa is (a) Omnivorous (b) Pseudopodia feeder [Odisha JEE 2005] (c) Holozoic nutrition (d) Photoautotroph (a) Anisogamy (b) Plasmotomy Which is not related with the sexual reproduction in 44. (c) Autogamy (d) Schizogony [Odisha JEE 2004] 31. Paramoecium exhibits cytoplasmic inheritance through (a) Cytogamy (b) Autogamy [BHU 2012] (c) Conjugation (a) Chromosome (b) Nuclear gene (d) Schizogony All protozoans have (c) Kappa particles (d) DNA [Odisha JEE 2004] Class sporozoa of phylum protozoa is characterised by 32. (a) Pseuopodia (b) Eukaryotic organisation [CMC Vellore 1993] (c) Contractile vacuole (d) Holozoic nutrition (a) Flagella (b) Cilia 46. is not true for Euglena [Odisha JEE 2004] (c) Parasitism (d) None of these (a) Presence of chl. - 'a' and 'b' 33. Primary grouping of protozoan protists is based on (b) Presence of protoplasmic capsule [MP PMT 1996, 99, 2002, 10; CPMT 1998; AIIMS 1999; (c) Presence of cellulose cell wall Pb. PMT 2002; DPMT 2002; AFMC 2009] (d) Presence of proteinaceous pellicle (a) Locomotor organelles (b) Size and shape A metazoa without tissue organisation is called (c) Mode of feeding (d) Mode of reproduction 34. Amoeba was described in detail by [Pb. PMT 2004] [RPMT 1999] (a) Parazoa (b) Protozoa (a) Ronald Ross (b) Aristotle (c) Eumetazoa (c) Hirshfield (d) Dermatozoa (d) Rossenhoff 48. Passive food ingestion in Amoeba is known as 35. Conjugation in protozoa is found in [RPMT 2001] [DPMT 2004; BHU 2004] (a) Sarcodina (b) Flagellata (a) Import (b) Invagination (c) Sporozoa (d) Ciliata (c) Circumfluence (d) Circumvallation Which one of the following represents class Mastigophora Reproduction in Paramecium is controlled by [BVP 2001] [MP PMT 2001] (a) Flagella (a) Monocystis (b) Paramecium (b) Micronucleus (c) Trypanosoma (c) Macronucleus (d) Amoeba (d) Cell wall 37. Maurer's dots occurs in human RBCs infected by 50. Trichonympha is a symbiont in alimentary canal of [MP PMT 2002] [APMEE 2002] (a) Plasmodium falciparum (b) Plasmodium ovale (a) Earthworm (b) Snails (c) Plasmodium vivax (d) Plasmodium malariae (c) Hermit Crab (d) Termite

(e) Euglena

51.	In which of the following binary fission is not seen	63.	Which structure is formed at the time of exchange of ganuclei in given animal during sexual reproduction	mete
	[Odisha JEE 2005]		그는 얼마나 가는 얼마나 하는 말이 되었다. 그리고 있는 것은 말이 되었다. 그는 그들은 그들은 그들은 그는 그를 모르는 것이 되었다.	01=1
	(a) Plasmodium (b) Amoeba		[GUJCET 2	.013
	(c) Euglena (d) Paramecium			
52.	Amoeba is a member of Phylum [MP PMT 2012]			
	(a) Porifera (b) Protozoa			
	(c) Annelida (d) Mollusca			
53.	Which of the following is a flagellated protozoan [Kerala PMT 2010, 12]			
	(a) Amoeba (b) Entamoeba			
	(c) Plasmodium (d) Trypanosoma			
	(e) Paramecium			
54.	Mammalian kidney resemble contractile vacuole of Amoeba in excretion of [MP PMT 2006]			
	(a) Glucose (b) Excess water			
	(c) Urea (d) Ammonia		(a) Plasmodesmata (b) Cytoplasmic filamen	s
55.	In Paramecium, both autogamy and conjugation are sexual		(c) Internal tubule (d) Cytoplasmic bridge	
	processes because of	64.	Entamoeba differs from Amoeba is not having

(c) Slime moulds

(d) Chrysopytes

Protista (Unicellular eukaryotes) 69 UNIVERSAL Locomotory structures of Amoeba are [BHU 2001] 86. Erythrocytic cycle of Plasmodium occurs in (a) Cilia (b) Flagella (a) Liver (b) Spleen (c) Pseudopodia (d) None of the above (c) RBC (d) Gut 75. Mode of nutrition in Trypanosoma is [DPMT 2006] 87. Which one is correct pairing [Manipal 2001] (a) Saprozoic (b) Parasitic (a) Hydra-Anthozoa (b) Paramecium-Arachnida (c) Autotropic (d) Phototropic (c) Plasmodium-Sporozoa (d) Amoeba-Ciliata 76. Quartan malaria is due to 88. Presence of two types of nuclei, micronucleus and [NCERT; RPMT 1995; Bihar CECE 1995; macronucleus, is characteristic of protistan group Odisha JEE 1995, 2005; BHU 1996; MP PMT 2001] (a) Sporozoa (b) Ciliata Or (c) Flagellata (d) Sarcodina Your patient shows paroxysms of malaria after every 72 89. Which one resides in the mouth of human beings hours. Which species of plasmodium will be considered [MP PMT 1995] responsible to cause the infection (a) Entamoeba coli (b) Entamoeba histolytica (a) Plasmodium falciparum (b) P. vivax (c) Entamoeba gingivalis (d) Amoeba proteus (d) P. malariae 90. Which one does not spread disease Malignant tertian malaria is due to INCERT [RPMT 1995; Pb. PMT 2000] (a) Entamoeba coli (b) Entamoeba histolytica Cerebral malaria is due to (c) E. gingivalis (d) Plasmodium ovale [CBSE PMT 1991; APMEE 1995, 2002; Which one is monogenetic parasite [RPMT 1995] Bihar MDAT 1996, 2002; RPMT 2000, 06; (a) Plasmodium (b) Liver Fluke AIIMS 2000; MP PMT 2004; BHU 2008; Odisha JEE 2009] (c) Taenia solium (d) Entamoeba histolytica (a) Plasmodium falciparum (b) P. vivax 92. (c) P. ovale Amoeba touched with needle will (d) P. malariae [RPMT 1995] 78. Male mosquito (Anopheles) does not transmit malarial (b) Divide quickly (c) Develop pseudopodia (d) Move away parasite because (a) It lacks blood sucking mouth parts 93. Infective stage of Trypanosoma gambiense is [APMEE 1995; AIIMS 1999; DPMT 1999] (b) It catches fever (a) Metacyclic (b) Crithidial (c) It is too small to carry parasite (c) Leptomonas (d) Leishmania (d) The parasite is killed in its stomach Which does not occur in sporozoa 94. [Bihar MDAT 1995] Highest incubation period occurs in Plasmodium (a) Cilia (b) Pseudopodia [CPMT 2001] (c) Flagella (d) None of the above (a) P. malariae (b) P. vivax 95. In malaria, which causes chills and fever [NCERT: (c) P. ovale (d) P. falciparum BHU 1995; MPPMT 1997] 80. Entamoeba histolytica infection occurs through (a) Contaminated water and food Metabolic waste responsible for malaria fever is called (b) Sweat Or (c) Bird droppings The poisonous substance released as a result of rupturing of (d) Mosquito bites schizont in RBC of malaria patient is [RPMT 2005] 81. Malarial parasite is [Bihar PMT 2000] (a) Hematinj (b) Haemozoin (a) Polygenetic (b) Digenetic (c) Schuffner's granules (d) Hematocrit 96. Development and functioning of gametocytes of (c) Monogenetic (d) Monomorphic Plasmodium in the body of Mosquito are dependent upon Type of pseudopodia present in Amoeba proteus is [RPMT 1996] (a) Lobopodia (b) Axopodia (a) Temperature (b) Food (c) Filopodia (d) Exopodia (c) Position Erythrocytic phase of Plasmodium vivax is completed in (d) All the above 97. Who was awarded Nobel Prize in 1902 for discovery of [Bihar PMT 2000] oocyst of Plasmodium [RPMT 1996] (a) 24 hours (b) 72 hours Or (c) 36 hours (d) 48 hours

Schuffner's dots observed in erythrocytes are due to

that is passed in female Anopheles is

(b) Pre-erythrocytic schizogony

(c) Exoerythrocytic schizogony

(d) Post-erythrocytic schizogony

The part of life cycle of malarial parasite Plasmodium vivax,

(b) Malaria

(d) Giardia

[CBSE PMT 1992]

(a) Filaria

(c) Kala-azar

(a) Sexual cycle

Who discovered oocysts in the stomach of female Anopheles

Malaria is transmitted by "Anopheles". This was discovered by

(b) Ronald Ross

(d) Shortt

(b) Ookinete

(d) Sporozoite

Or

Which one is spindle-shaped mobile with microtubules

(a) Golgi

98.

(c) Laveran

(a) Sporont

(c) Cryptozoite

[MP PMT 2009]

[RPMT 1996]

9.	Infection of Entamoeba histoloytica is prevented by [CPMT 1996]	113.	Infective stage of Entamoeba histolytica is [CPMT 1997; Manipal 1999; Pb. PMT 1999; BHU 2002]
	(a) Avoiding kissing		(a) Trophozoite (b) Pre-cyst
	(b) Avoiding clothes of patient		(c) Uninucleate cyst (d) Tetranucleate cyst
	(c) Uncontaminated food	114	Sandfly is causative agent of
	(d) None of the above		[CPMT 1997; AMU (Med.) 2001; MP PMT 2002]
.00	Trichocyst takes part in [CPMT 1996]		(a) Kala-azar (b) Sleeping sickness
	(a) Defence (b) Reproduction		(c) Typhoid (d) Dysentery
	(c) Nutrition (d) Osmoregulation	115	
01.	Cyst wall of Euglena is formed of [APMEE 2000, 02]	115.	Leishmania tropica produces
	(a) Silica (b) Carbohydrate		[AMU (Med.) 1998; MP PMT 2011]
	(c) Proteins (d) Calcium		(a) Sleeping sickness (b) Kala-azar
02.	Posterior end of Amoeba is characterised by		(c) Dysentery (d) Oriental sores
	[Bihar MDAT 1996]	116.	Trypanosoma brucei produces [BHU 1998]
	(a) Plasmid (b) Amphid		(a) Sleeping sickness (b) Kala-azar
	(c) Uripygium (d) Lack of food vacuoles		(c) Dysentery (d) A disease of animals
03.	Multiple fission in Plasmodium is [DPMT 1996]	117.	Which of the following does not belong to the kingdom
	(a) Gamogamy (b) Schizogony		Protista [Kerala PMT 2011]
222	(c) Sporulation (d) None of the above		(a) Chrysophytes (b) Euglenoids
04.	Development of gametocyte from merozoite of Plasmodium		(c) Ascomycetes (d) Dinoflagellates
	occurs in [DPMT 1996]		(e) Protozoans
	(a) Red blood corpuscles	110	
	(b) Liver cells	110.	Protozoan found commensal in human colon is
	(c) Stomach of female Anopheles		[CPMT 1998; DPMT 2006]
	(d) All the above		(a) Entamoeba coli (b) P. vivax
05.	A cyst of Entamoeba histolytica produces trophozoites		(c) A. aegypti (d) All the above
	[DPMT 1996]	119.	Symptoms of paroxysms in malaria are due to [RPMT 1998]
	(a) 1 (b) 2		(a) Sporozoite (b) Gametocyte
06	(c) 4 (d) 18 Which one is not a symptom of Entamoeba histolytica		(c) Pre-erythrocytic cycle (d) Erythrocytic cycle
00.	infection [BHU 1996]	120.	Relapsing malaria is due to [RPMT 1998]
	(a) Relapsing fever (b) Abdomial pain		(a) Plasmodium falciparum and P. vivax
	(c) Blood in stool (d) Irregular bowels		(b) Plasmodium ovale and P. vivax
07.	Malarial species found in South America and West Africa is		(c) Plasmodium falciparum and P. ovale
	[BHU 1996]		(d) P. falciparum only
	(a) Plasmodium falciparum (b) P. vivax (c) P. malariae (d) P. ovale	121.	Study the following figures and identify A, B and C [NCERT]
08.	Recurrence of high temperature in malaria at intervals is due to completion of [BHU 1996; AIIMS 1996; CPMT 1997]		9 500
	(a) Erythrocytic schizogony		1000
	(b) Sporogony		(Carrier Carr
	(c) Gamogony		
09.	(d) Exoerythrocytic schizogony Symptoms of malaria in spleen and skin are due to		A B

	(c) Contractile vacuole (d) Malpighian tubles		F. St
11	What is common about Trypanosoma, Noctiluca,		
	Monocystis and Giardia [CBSE PMT 2006]		
	(a) They produce spores		C
	(b) These are all parasites		(a) A – Euglena, B – Paramecium, C - Aspergillus
	(c) These are all unicellular protists		(b) A – Planaria, B – Paramecium, C - Agaricus
	(d) They have flagella		(c) A – Euglena, B – Planaria, C - Agaricus
12.	Which one of the following is a characteristic feature of		(d) A – Euglena, B – Paramecium, C – Agaricus
	Chrysophytes [Kerala PMT 2011]	122.	Signet ring stage of Plasmodium represents
	(a) They are parasitic forms which cause diseases in		[MP PMT 1999; CPMT 2010]
	animals		(a) Beginning of schizogony in liver cells
	(b) They have a protein rich layer called pellicle		사회에서 그 사람들은 사람들은 그리고 그 아내는 사람들이 있다. 그는 사람들이 가장하는 그는 그리고 있는 것이 없는 것이다.
	(c) They have indestructible wall layer deposited with silica		(b) End of schizogony in RBC
	(d) They are commonly called dinoflagellates		(c) Beginning of schizogony in RBC
	(e) They are saprophytic protista		(d) Beginning of sporogony in humans

- 123. Amoeba is eukaryotic because it possesses [APMEE 1999]
 - (a) Plasmid (c) Plasmalemma
- (b) Nucleus (d) DNA
- 124. Incubation period of Plasmodium vivax is

[DPMT 1999; WB JEE 2009; MP PMT 2012]

- (a) 14 days
- (b) 20 days
- (c) 30 days
- (d) 45 days
- 125. In Amoeba, contractile vacuole is present

[CPMT 2000; BHU 2006]

- (a) Near trailing end
- (b) Near advancing end
- (c) At the middle of body
- (d) Any where inside body
- 126. Select the wrong statement
- [NEET (Phase-II) 2016]
- (a) Diatoms are microscopic and float passively in water
- (b) The walls of diatoms are easily destructible
- (c) 'Diatomaceous earth' is formed by the cell walls of diatoms
- (d) Diatoms are chief producers in the oceans

Critical Thinking

Objective Questions

1. The major function of contractile vacuole is

[CBSE PMT 1995; CPMT 1996; RPMT 2000; BHU 2006]

- (a) Excretion
- (b) Circulation
- (c) Osmoregulation
- (d) All the above
- Centric discoid form of diatom is
- [HPMT 2001]

- (a) Diploneis
- (b) Coscinodiscus
- (c) Stephanodiscus
- (d) Camphyloneis
- 3. Which of the following can be used as bacteriological filter
 - [JIPMER 2002]
 - (a) Gelidium (c) Oscillatoria
- (b) Batrachospermum (d) Cymbella
- Two species of Amoeba X and Y were kept in fresh water and got adapted. Species X developed contractile vacuole. When both were transferred to sea water and got adapted, both X and Y lost their contractile vacuole. From these observation we conclude that
 - (a) Both X and Y are marine species
 - (b) Species Y is marine and X is fresh water
 - (c) Species X is marine and Y is fresh water
 - (d) Both X and Y are fresh water
- 5. Amoeba reacts
 - (a) Negatively to strong light and positively to weak light
 - (b) Positively to strong light and negatively to weak light
 - (c) Unaffected by light intensity
 - (d) Positive to both strong and weak light
- Which is wrong combination
- [AIIMS 2001]
- (a) Haemocyanin Prawn
- (b) Haemoglobin in mammals RBC
- (c) Haemoglobin in plasma Pheretima
- (d) Haemozoin Plasmodium cytoplasm
- 7. Plasmodium, the malarial parasite, belongs to class
 - [NCERT; CBSE PMT 1990]
 - (a) Sarcodina
- (b) Ciliata
- (c) Sporozoa
- (d) Dinophyceae

- 8. Periodic appearance of malaria symptoms occurs due to periodic
 - (a) Entry of merozoites into erythrocytes
 - (b) Attack of liver cells by merozoites
 - (c) Formation of signet ring
 - (d) Release of pyrogen in blood
- 9. Motile elongate zygote of Plasmodium occurs in

[NCERT; CPMT 1999; CBSE PMT (Pre.) 2012]

- (a) Human RBCs
- (b) Human liver
- (c) Salivary glands of mosquito (Anopheles)
- (d) Gut of mosquito (Anopheles)
- 10. In Amoeba, pseudopodia are formed due to [RPMT 1995]
 - (a) Contact with food
 - (b) Sol ≥ gel change
 - (c) Movement towards area of higher temperature
 - (d) All the above
- 11. Which stage of Plasmodium is infective for Mosquito

[RPMT 1996]

- (a) Trophozoite
- (b) Gametocyte
- (c) Ookinete
- (d) Sporozoite
- 12. Chromatid bodies occurs in Entamoeba during
 - [APMEE 1996; Pb. PMT 1999; AIIMS 2002]
 - (a) Precyst stage
- (b) Early cysts
- (c) Tetranucleate cysts
- (d) Trophozoites
- Amoeba stops producing pseudopodia during
 - [HPMT 2001]

[RPMT 2002]

- (a) Alkaline condition
- (b) Starvation (d) Touch
- (c) Acidic condition
- After how many days could a patient commonly feel malaria 14. from the time of biting of mosquito [CPMT 1998]
 - (a) 2 8 days
- (b) 8 10 days
- (c) 10 20 days
- (d) 20 30 days
- 15. Microfossile often present in petroleum producing formation are those of [AMU (Med.) 2001]
 - (a) Radiolarians
- (b) Diatoms
- (c) Helizoans
- (d) Foraminiferans
- 16. Amoeba moves when
 - (a) Upper part of plasma-gel changes to plasmasol
 - (b) Lower part of plasmasol changes into gel
 - (c) Upper part of plasmasol changes into plasmagel (d) All the above
- A person suffering from a disease caused by Plasmodium, experiences recurring chill and fever at the time when

[NCERT; CPMT 1998; AFMC 2001; CBSE PMT (Mains) 2010]

- (a) The sporozoites released from RBCs are being rapidly killed and broken down inside spleen
- (b) The trophozoites reach maximum growth and give out certain toxins
- (c) The parasite after its rapid multiplication inside RBCs ruptures them, releasing the stage to enter fresh RBCs
- The microgametocytes and megagametocytes are being destroyed by the WBCs
- Destruction of nucleus in Amoeba results in [RPMT 1995]
 - (a) Immediate death
 - (b) Slowing down of metabolic activity and ultimate death
 - (c) Quick locomotion
 - (d) No change

- Exoerythrocytic schizogony of Plasmodium takes place in [MP PMT 2007]
 - (a) RBC
 - (b) Leucocytes
 - (c) Liver in which cryptomerozoites are formed
 - (d) Liver in which metacryptomerozoites are formed
- 20. In Plasmodium, gametocytes are formed from

[Bihar PMT 1994]

- (a) Schizont
- (b) Trophozoite
- (c) Sporozoite
- (d) Merozoite
- 21. If all ponds and puddles are destroyed, the organism likely to be destroyed is [CBSE PMT 1993]
 - (a) Leishmania
- (b) Trypanosoma
- (c) Ascaris
- (d) Plasmodium
- 22. The chill and fever recurring after 48 hours in benign tertian malaria is due to
 - (a) Plasmodium vivax
- (b) P. malariae
- (c) P. falciparum
- (d) None of the above
- 23. In malaria, shivering occurs when

[AFMC 2001;

- RPMT 2002; CPMT 2004; WB JEE 2012]
- (a) Schizonts enter R.B.C.
- (b) Sporozoites enter human body
- (c) Merozoites are liberated from R.B.C. alongwith toxin
- (d) Signet ring stage is attained
- 24. Which one of the following sets of items in the options a-d are correctly categorized with one exception in it

[NCERT; CBSE PMT (Mains) 2012]

	Items	Category	Exception
(a)	UAA, UAG, UGA	Stop codons	UAG
(b)	Kangaroo, Koala, Wombat	Australian marsupials	Wombat
(c)	Plasmodium, Cuscuta, Trypanosoma	Protozoan parasites	Cuscuta
(d)	Typhoid, Pneumonia, Diphtheria	Bacterial diseases	Diphtheria

25. Which of the following diseases is caused by a protozoan

[AIPMT 2015]

- (a) Influenza
- (b) Babesiosis
- (c) Blastomycosis
- (d) Syphilis
- 26. All eukaryotic unicellular organisms belong to
- belong to [NCERT]

- (a) Monera
- (b) Protista
- (c) Fungi
- (d) Bacteria

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true

- 1. Assertion : Slime moulds show alternation of
 - generation.
 - Reason : The sporangia bearing slime moulds
 - represent haplophase.
- 2. Assertion : Sandfly transmits Kala-azar.
 - Reason : In Kala-azar, the parasite damages the
 - brain.
- 3. Assertion : Trichomonas vaginalis causes infection only in women.
 - Reason : Trichomonas buccalis lives in the buccal
- 4. Assertion : Euglena is studied as an animal as well as a
- 4. Assertion : Euglena is studied as an animal as well as plant.
 - Reason : Euglena is more an animal than a plant.
- 5. Assertion : Amoeba contains a contractile vacuole.
 - Reason : It helps in both digestion and osmoregulation.
- 6. Assertion : Amoebiasis is caused by Amoeba.
- Reason : The protist feeds on red blood corpuscles.
- 7. Assertion : Erythrocytic merozoites form gametocytes.
 - Reason : Gametocytes are of two types male and female.
- 8. Assertion : Plasmodium causes disease in female Anopheles mosquitoes.
 - Reason : Female Anopheles mosquitoes feed on
 - human blood.
- 9. Assertion : Malarial fever appear at merozoite stage of
 - Plasmodium.
 - Reason : The infective stage of *Plasmodium* is sporozoite.
 - C 1:
- 10. Assertion: Schizogony is an asexual reproduction of
 - female Anopheles mosquito.
 - Reason: It takes place only in human liver cells.

Answers and Solutions

Photosynthetic and consumer protists

- (a) Free floating living protist are collectively called plankton, which are float on the water surface.
- (c) Because in sea ecosystem, phytoplanktons are primary producers, if they are destroyed, naturally food chain will be disturbed.
- 8. (c) The slime moulds are included into the division myxomycota by mycologists. The spores of slime moulds (acellular) germinate to produce biflagellate swarm cells which function as gametes.

- (c) Capillitium is a branched system of five tubes present in acellular slime moulds. Elaters and pseudoelaters are present in some bryophytes where as capitulum is a type of inflorescence.
- 12. (c) They are unicellular, photosynthetic, eukaryotes.
- (b) Red tides of oceans are due to excessive growth of dinoflagellates like Gymnodinium and Gonyaulax.
- 15. (b) Slime moulds are consumer protist.
- (c) In slime moulds the multinucleate protoplasma of a sporangium, undergoes cleavage to form spores.
- 17. (d) The cells of dinoflagellate are generally covered by theca or lorica. Theca contains two grooves, the longitudinal groove called sulcus and transverse groove known as cingulum or annulus or girdle.
- 19. (b) By binary fission the cells of Paramecium divide transversly. In conjugation two paramecia come in contact in the region their oral groove and establish protoplasmic bridge
- 21. (c) Enterobius vermicularis is a member of Nemathelminthes.
- **25.** (c) Auxospores are generally called rejuvenescent cells because they help in increasing diatom size to normal one. Auxospores are commonly formed form zygote.
- (d) Mixotrophic nutrition is found in Euglena, when light is available it is photosynthetic in darkness, it is saprophytic.
- 29. (a) Frustule of diatoms is made of silica, cellulose and pectic compounds.
- **31.** (d) Amoeba and Paramecium are protozoan protist while dinoflagellates are photosynthetic protist.

Protozoan protists

- 7. (d) Parapodia is the locomotory organ of Nereis (Annelida).
- (b) Animals of class sarcodina or rhizopoda have pseudopodia as locomotory organ.
- 24. (c) Being unicellular, no specific excretory system develop so this function can be performed by plasmalemma by diffusion process.
- **25.** (b) Pseudopodium is formed due to different viscosity of sol and gel.
- 32. (c) Members of this class are exclusively endoparasites.
- (c) Amoeba was discovered by Rossenhoff (1755) and described by H.I. Hirshfield.
- **35.** (d) Conjugation is shown by *Paramecium* which strictly belongs to ciliata of Protozoa.
- (a) Maurer's dots are green coloured structure which are found in erythrocytic cycle of Plasmodium falciparum.
- 39. (d) Protists are primitive single celled organism with well organised nucleus, which shows auto as well as heterotrophic mode of nutrition.
- **43.** (d) *Amoeba* is omnivorous and its mode of nutrition is holozoic. It feeds by phagocytosis. *Amoeba* captures and engulfs its prey by means of pseudopodia.
- **48.** (a) Import involves passive sinking of food into body by rupture of plasmalemma, *e.g.*, Ingestion of algae.
- 49. (b) Micronucleus is usually spherical, with a nuclear membrane and with diploid number of chromosomes. It controls the reproductive activities of the organism.

- 50. (d) Trichonympha is a symbiont in alimentary canal of termites. Trichonympha secretes cellulose digesting enzyme β glucosidase which convert cellulose into glucose.
- 54. (b) Single contractile vacuole is found in fresh water Amoebae. It appears like a bubble of clear, watery fluid, enclosed within a delicate and elastic condensation membrane resembling plasmalemma. Its function is osmoregulation, i.e., excess amount of water collected in it and discharged out by it. The water collected in contractile vacuole contain trace of ammonia.
- 56. (b) While female Anopheles suck the infected blood then various phases of malaria parasite reach in their stomach, where digestive enzymes digest all phases besides gametocyte.
- **61.** (d) Magna (Trophozoite) stage of *Entamoeba histolytica* feeds on mucus and RBC.
- **64.** (d) Absence of contractile vacuole in *E.histolytica* is a distinguish feature from *Amoeba*.
- 65. (c) The cilia of extreme posterior end are longer and form a bunch called caudal tuft.
- 66. (c) When kerosine, paraffin and petroleum oil is sprinkling over pond, then larva and pupa of mosquito die after some time due to difficulty of breathing. Difficulty of breathing is known as asphyxia.
- 68. (d) During favourable conditions, Paramecium commonly reproduces by transverse or horizontal binary fission which is at right angles to the longitudinal axis of the body. Paramecium stops feeding and oral groove and buccal structures begin to disappear. The micronucleus starts dividing by the complicated process of mitosis. After separation of daughter micronuclei, the macronucleus divides amitotically.
- (d) Diatoms (chrysophytes) body is look like soap box and fit together.
- phylum 75. Trypanosoma protozoa. (b) belongs to Trypanosoma gambiense is unicellular and causes African sleeping sickness in man. This is parasite and lives in the blood stream and lymph glands of infected person in early stage of disease. Among animals Euglena contains chlorophyll and therefore, photo autotrophic in nature. Euglena is considered as connecting link between plants and animals. Few animals secrete digestive enzymes directly into their food outside the body and they are called saprozoic e.g., spiders, housefly etc.
- **80.** (a) Infection depends upon intake of food or water contaminated with faecal matter containing tetranucleated cyst of *E. histolytica*.
- 81. (b) Malarial parasite is digenetic because its life cycle completed in two different hosts. Primary or principal host is man and secondary intermediate or vector host is female Anopheles.
- 85. (a) Both type of gamete are formed during sexual cycle, which occurs in female Anopheles.
- **88.** (b) Two different type of nucleus, present in ciliata group are micronucleus and macronucleus. Micronucleus take part in reproduction while macronucleus is large kidney shaped which control matabolism.
- **90.** (a) Entamoeba coli inhabits human colon and feed only bacteria and debris which are present there. Hence Entamoeba coli neither harmful nor beneficial.

- **92.** (d) Amoeba will move away from contact with a foreign object or a probe while crawling or resting.
- (a) Metacyclic form is a infective stage of Trypanosoma gambiense which are formed in lumen of salivary gland.
- (d) All animals of sporozoa are endoparasite, so they have no any locomotory organs. It is a parasitic adaptation.
- 98. (d) Sporozoites are spindle or sickle shaped and uninucleated organism capable of wriggling movement. Each has a covering form but elastic pellicle containing longitudinal contractile microtubule.
- 103. (b) Asexual cycle passed in man by process termed schizogony (schizogony in liver and R.B.Cs). Schizogony is a type of multiple fission.
- 109. (b) Haemozoin is yellow brown to blackish and insoluble polymer of ferriprotoporphyrin. It is formed by haematin or breakdown product of haemoglobin. It collect in various tissues, e.g., spleen, skin.
- 113. (d) Tetranucleate (= Quadri) cyst is infected stage of Entamoeba histolytica. Infection is oral through contaminated food and water.
- **114.** (a) Leishmania donovani is the parasite of kala-azar or dumdum fever. These parasite is transmitted by sand fly.
- 115. (d) Leishmania tropica produce skin ulcers known as oriental sore or Delhi sore, which is spread by sand fly.
- **126.** (b) The cell walls of diatoms are embedded with silica and thus the walls are indestructible.

Critical Thinking Questions

- (c) The major function of contractile vacuole is osmoregulation, i.e., removal of excess of water.
- (a) Amoeba responds to light, positive behaviour towards moderate lights, negative behaviour to strong light and darkness.
- 6. (d) Haemozoin liberated in blood plasma.
- 8. (d) Paroxysm is the actual attack of malaria which initially begins after a few earliest erythrocytic cycles, but it is, then repeated after every cycle. Obviously paroxysm result due to sufficient accumulation of haemozoin and other toxins in blood.
- (d) The motile zygote formed by fertilization of macrogamete by a microgamete is called ookinete. It occurs in gut of mosquito.
- 10. (b) According to pressure or ectoplasmic concentration or sol-gel theory, pseudopodia are formed and withdrawn due to cyclic viscosity change in the colloidal cytoplasm from 'sol to gel' and 'gel to sol' states.
- (b) Gametocyte is infective stage for female anopheles mosquito because optimum temperature for growth of gametocyte is present in their body.
- 12. (b) Initial stage of cyst formation, two or more transparent rod like structure are present in cytoplasm called chromatid bodies. These chromatid bodies are made of ribonucleoprotein.
- **13.** (b) During starvation, *Amoeba* stops producing pseudopodia and covered with hard impervious and chitinous protective layer or cyst wall for the protection and survival as well as dispersal of *Amoeba*.
- **14.** (b) The patient displays symptoms of malaria fever after a period of 8-10 days from infectious bite.
- **16.** (c) Amoeba move, when cytoplasm change from sol to gel or gel to sol state.

- 17. (c) In malaria chill and fever is due to the release of haemozoin, a toxic substance formed by breakdown of haemoglobin present in RBC. It will be released after the rupture of RBC, in erythrocytic schizogamy.
- 19. (d) The cryptomerozoite formed during pre-erythrocytic schizogony may enter the human RBCs to start the erythrocytic schizogony, while some of them enter new liver cells and reproduced asexually to give rise to a large number of meta-cryptomerozoites few are smaller in size and called micro-meta-cryptomerozoites.
- (d) Gametocytes of malarial parasite are developed from merozoites in RBCs of man.
- 23. (c) Infected R.B.Cs rupture that merozoites and haemozoin granules are liberated in blood. Haemozoin granules are toxic and bring about fever.
- 25. (b) Babesiosis is caused by sporozoan protozoan- babesia. In this disease haemoglobinuric fever occur.
- (b) They are solitary unicellular or colonial unicellular eukaryotic organisms.

Assertion and Reason

- 1. (c) Slime moulds exhibit alternation of generation. The diploid plasmodium is a sporophyte. Under certain conditions it bears sporangia. The sporangia bearing plasmodium and spore producing sporangia constitute the sporophyte generation. It is diplophase reduction division takes place at the time of differentiation of resting spore. The resting spores germinate to produce the haploid, uninucleate swarm cells or myxamoebae. The latter meet and fuse in pairs to form a zygote. The haploid resting spores and the swarm cells or myxamoebae represent the haploid or gametophyte generation.
- 2. (c) Leishmania donovani causes kala-azar. The parasite is transmitted by sandfly. The parasite lives inside the cells of liver, spleen, lymph glands, white blood corpuscles and inner wall cells of blood capillaries. In sleeping sickness disease, the parasite damages the brain.
- 3. (e) Trichomonas vaginalis inhibits vagina of women and causes the disease known as leucomhoea. In males the parasite produces irritation in urethra. Trichomonas buccalis resides in the buccal cavity, which is nearly harmless.
- 4. (b) Euglena is a typical example of mastigophora. It is phytoflagellate as it possesses both chloroplast and flagella. It is autotrophic in sunlight, but becomes heterotrophic in dark. Because of its two fold nutritional abilities, it is usually studied as a plant as well as an animal. But it is more an animal than plant because of
 - (a) The absence of cellulose cell wall overlying the plasma membrane.
 - (b) Presence of centriole forming blepharoplasts.
 - (c) Reserve food is paramylon which is not a true starch.
 - (d) Response to various stimuli like an animal.

- 5. (c) Contractile vacuole in Amoeba is a single, clear rounded pulsating structure which is filled with a watery fluid and enclosed by a unit membrane. It helps in the osmoregulation and excretory activities. Digestion in Amoeba occurs in the food vacuoles. These are spherical species small and large, contain water and food in various phases of digestion. As soon as the egestion of non digestible food occurs through body these get disappear.
- 6. (e) Person suffering from amoebic dysentry has repeated blood mixed, slimy and foul smelling motions and causes the disease known as amoebic dysentery or amoebiasis. This protist feeds on red blood corpuscles by damaging the wall of large intestine and reaching the blood capillaries.
- (b) Some erythrocytic merozoites enter fresh RBCs. And form rounded gametocytes (gamonts). The gametocytes are of two types – (i) Smaller male gametocytes or microgamete and (ii) Larger female gametocytes or macrogametocytes.
- 8. (e) The sexual phase of the malarial parasite occurs in the Anopheles mosquito. As the female Anopheles mosquitoes feed on blood, only they can serve as vector hosts of malarial parasites. The parasite does not harm the mosquito.
- (b) When the mosquito bites man, sporozoites present in the salivary gland of female Anopheles mosquito are injected into the blood of the man. The erythrocytic schizont gives rise to merozoites. Malaria fever occurs when schizonts in red blood corpuscles burst and set free their contained merozoites and malarial pigment (haemozoin) in the blood plasma. Bursting of schizonts tends to be synchronous as they all burst at the same time. Haemozoin is said to be toxic and so includes high fever and shivering (Haemozoin is an unused hematin, which is produced by the breakdown of haemoglobin). It is yellow brown to blackish in colour.
- 10. (c) Schizogony is an asexual reproduction in which schizont is formed. From the human blood sporozoites enter the liver cells. The sporozoite grows in size to become a rounded schizont called cryptozoite. The latter divides to form cryptomerozoites. cryptomerozoites formed during pre-erythrocytic schizogony may enter the human RBCs to start the erythrocytic schizogony, while some of them enter new liver cells to repeat hepatic (liver) schizogony.

- (b) Amoeba forms a cyst and reproduces by multiple fission, during adverse environmental condition.
- 4. (c) Paramecium caudatum shows nuclear dimorphism. There are two type of nuclei – a large bean shaped polyploid vegetative nucleus called macronucleus and a small rounded diploid reproductive nucleus known as micronucleus.
- 5. (c) Amoeba reproducing by binary fission, the parent becomes wholly murged in the offspring. Thus, there exists a continuity of life, so that amoeba is potentially immortal and it is scattered all over the world.

- 7. (a) Giardia intestinalis causes Diarrhoea.
- (d) Trypanosoma is usually found in the blood of vertebrates, finally invading cerebrospinal fluid.
- 10. (b) The cellular slime moulds are now classified with the Amoebas because of their evolutionary closeness and these slime moulds have cellular amoeboid stage. The other phyla of slime moulds are the plasmodial slime moulds or Myxomycota.
- (a) Trypanosoma is polymorphic and has four forms: Leishmania, Leptomonad, Crithidial and Trypanosomal stages.
- 16. (b) Protozoans are acellular eukaryotic organisms included in the division protista. They are basically animals previously included under nonchordates. As because they are animals they lack any cell wall. Cell wall is present in plant cells outside cell membrane. The main function of the cell wall is to provide mechanical strength.
- 18. (c) The structures presents in Amoeba are pseudopodia, plasmalemma, nucleus, contractile vacuole, Food vacuole, water globules, endoplasmic reticulum, ribosomes, golgi bodies, mitochondria, lysosomes and microtubules.
- 19. (b) Plasmalemma possesses numerous fine, ridge-like extension on its outer surface. Due to presence of these it have adhesive properties and serve to bind the animalc ule to the substratum.
- 20. (a) The motile diploid zygote formed by fertilization (anisogamy) of macrogamete by a microgamete is called ookinete. Ookinete penetrates the stomach wall and forms encysted zygote called oocyst or sporont.
- 23. (d) Pseudopodium at its forward end gets its firm consistency by hyaline cap which is made of ectoplasm.
- 26. (a) The diploid micronucleus of each conjugant divides by meiosis. Thus, 4 haploid daughter micronuclei are produced of which 3 degenerates in each conjugant, while the remaining one divides by mitosis 2 unequal pronucleus.
- **27.** (c) Schizont is a stage in the history of malarial parasite occurring in R.B.Cs and liver cells.
- 28. (c) The first cycle of plasmodium occurs in liver cells which is harm for liver cell because sporozoite phagocytes the cytoplasm of the liver cells.

1.4

Fungi (Multicellular decomposers)

The terms 'fungus' has been derived from the Latin word which means mushroom. The science dealing with the study of fungi is called as mycology. Clausius (1601) may be regarded as one of the earliest writers to describe fungi. The term 'Fungus' was coined by Gaspard and Bauhin. Bauhin (1623) also included the account of known fungal forms in his book Pinax Theatric Botanica. Kingdom fungi has been called mycota by Von Arx (1981) and mycetae by Alexopoulos. Anton de Bary is known as 'Father of Modern Mycology and plant pathology'.

Famous Indian Mycologists: Dastur, Mundkar, Prof. K.C. Mehta (associated with study of annual recurrence of wheat rust in India), Thind, Srinivasan, K.G. Mukherji, Chaudhary and Sadasivan are other famous mycologists of India

Thallus organization

The plant body of true fungi (Eumycota) is **thallus**. It may be non-mycelial or mycelial. The non-mycelial forms are unicellular, however, they may form a **pseudomycelium** by budding. In mycelial forms, the plant body is made up of thread like structures called hyphae (sing. hypha). The mycelium may be **aseptate** (non-septate) or **septate**. When non-septate and multinucleate, the mycelium is described as **coenocytic**. In lower fungi the mycelium is non-septate *e.g.*, Phycomycetes. In higher forms it is septate *e.g.*, Ascomycetes, Basidiomycetes and Deuteromycetes. In some forms the plant body is unicelled at one stage and mycelial at the other. Their organization is sometimes described as **dimorphic**.

When the entire mycelium is converted into reproductive structure, the thallus is described as **holocarpic**. However, if only a part of it becomes reproductive, the thallus is called as **eucarpic**.

Specialised formation

In higher forms the mycelium gets organised into loosely or compactly woven structure which looks like a tissue called **plectenchyma**. It is of two types:

Prosenchyma: It comprises loosely woven hyphae lying almost parallel to each other.

Pseudoparenchyma: If the hyphae are closely interwoven, looking like parenchyma in a cross-section, it is called as pseudoparenchyma.

In addition to above, the fungal mycelium may form some specialized structures as under :

Rhizomorphs: It is a 'root or string-like' elongated structure of closely packed and interwoven hyphae. The rhizomorphs may have a compact growing point.

Sclerotia: Here the hyphae gets interwoven forming pseudoparenchyma with external hyphae becoming thickened to save the inner ones from desiccation. They persist for several years.

 ${\bf Stroma}:$ It is thick mattress of compact hyphae associated with the fruiting bodies.

Cell organization

The cell wall of fungi is mainly made up of chitin $(C_{22}H_{54}N_4O_{21})$ and cellulose. While chitin is a polymer of N-acetyl glucosamine, the cellulose is polymer of d-glucose. Precisely, the cell wall may be made up of cellulose-glucan (oomycetes), chitin-chitosan (Zygomycetes), mannan-glucan (Ascomycetes), chitin-mannan (Basidiomycetes) and chitin-glucan (some Ascomycetes, Basidiomycetes and Deuteromycetes). Besides, the cell wall may be made up of cellulose-glycogen, cellulose-chitin or polygalactosamine-galactan.

The cell wall is closely associated with the inner layer, the plasma membrane. In fungi, plasma membrane bears coiled membranes outgrowth called **lomasomes** (Moore and McAlear, 1961).

Fungi cells are eukaryotic. They possess all eukaryotic organelles such as mitochondria, E.R., ribosomes, microbodies, lysosomes, vacuoles and reserve food particles (glycogen, lipid etc.). Golgi body or dictyosome are also not typical. In many cases they are **unicisternal**. The cells lack chloroplast. However, a reddish pigment, **neocercosporin** has been isolated from the fungus *Cercospora kikuchii*. The vacuoles are bound by tonoplast. The genetic material is DNA.

Fungi possess true nucleus having definite nuclear envelope. The nuclear envelope persists during nuclear division. It has called **karyochorisis** by Moore (1965). The nuclear spindle is formed within the nuclear envelope in both mitosis and meiosis. The spindle poles either contain centrioles or spindle pole bodies (SPB) but lack microtubular organization.

Nutrition

The fungi are achlorophyllous organisms and hence they can not prepare their food. They live as heterotrophs *i.e.*, as parasites and saprophytes. Some forms live symbiotically with other green forms.

Parasites: They obtain their food from a living host. A parasite may be **obligate** or **facultative**. The obligate parasites thrive on a living host throughout their life. The facultative parasites are infact saprophytes which have secondarily become parasitic.

Saprophytes: They derive their food from dead and decaying organic matter. The saprophytes may be **obligate** or **facultative**. An obligate saprophyte remains saprophytic throughout it's life. On the other hand, facultative saprophyte is infect a parasite which has secondarily become saprophytic.

Symbionts: Some fungal forms grow in symbiotic association with the green or blue-green algae and constitute the **lichen**. A few fungal forms grow in association with the roots of higher plants. This association is called as **mycorrhiza**.

Reproduction

(1) Vegetative reproduction

Fragmentation: Some forms belonging to Ascomycotina and Basidiomycotina multiply by breakage of the mycelium.

Budding: Some unicelled forms multiply by budding. A bud arises as a papilla on the parent cell and then after its enlargement separates into a completely independent entity.

Fission : A few unicelled forms like yeasts and slime moulds multiply by this process.

(2) Asexual reproduction

Oidia: In some mycelial forms the **thallus** breaks into its component cells. Each cell then rounds up into a structure called oidium (pl. oidia). They may germinate immediately to form the new mycelium, e.g., Rhizopus.

Chlamydospores: Some fungi produce chlamydospores which are thick walled cells. They are intercalary in position. They are capable of forming a new plant on approach of favourable conditions, e.g., Rhizopus, Saprolengnia, Ustilago.

Sporangiospores: These are thin-walled, non-motile spores formed in a sporangium. They may be uni-or multinucleate. On account of their structure, they are also called as **aplanospores**. e.g., Rhizopus, Mucor.

Zoospores: They are thin-walled flagellate spores which occur in aquatic fungi. These spores are formed in a zoosporangium. The zoospores are of several types:

- ☐ Uniflagellate with whiplash type flagellum e.g., Allomyces.
- ☐ Uniflagellate with tinsel type flagellum e.g., Rhizidiomyces.
- ☐ Biflagellate with a tinsel type and a whiplash type flagella e.g., Saprolegnia.
- \square Biflagellate with two whiplash type flagella e.g., Plasmodiophora.

Conidia: In some fungi the spores are not formed inside a sporangium. They are born freely on the tips of special branches called **conidiophores**. The spores thus formed are called as conidia. e.g., Penicillium.

(3) **Sexual reproduction**: With the exception of Deuteromycetes (fungi imperfecti), the sexual reproduction is found in all groups of fungi. During sexual reproduction the compatible nuclei show a specific behaviour which is responsible for the onset of three distinct mycelial phases. The three phases of nuclear behaviour are as under:

Plasmogamy: Fusion of two protoplasts.

Karyogamy: Fusion of two nuclei.

Meiosis: The reduction division.

These three events are responsible for the arrival of the following three mycelial phases:

Haplophase: As a result of meiosis the haploid (n) or haplophase mycelium is formed.

Dikaryotic phase : The plasmogamy results in the formation of dikaryotic mycelium (n + n).

Diplophase: As a result of karyogamy the diplophase mycelium (2n) is formed.

The fungi reproduce sexually by the following methods

- ☐ Planogametic copulation: In this type of copulation fusion occur between flagellate gamete. It is of three types:
- (i) **Isoplanogametic copulation**: Both the fusion gametes are similar and flagellate. e.g., Synchytrium.
- (ii) **Anisoplanogametic copulation**: The fusing gametes are flagellate, similar in structure but different in size. In which one is small and other one is large. *e.g.*, *Allomyces*.

- (iii) **Ooplanogametic copulation**: It is union between a small flagellate male gamete and a large nonflagellate food laden female gamete or ovum. . e.g., Monoblepharella.
- ☐ Gametangial contact: It involves fusion of two gametangia. In lower forms the female gametangium is called as oogonium. The male gametangium is termed as antheridium. A contact develops in between the two gametangia and then the male nucleus is transferred into the female directly or through a tube. e.g., Phytophthora, Albugo.
- ☐ Gametangial copulation: In this case the fusion occurs in between the two gametangia. When it occurs in some holocarpic forms where the entire thallus acts as gametangium, the phenomenon is called as **hologamy**. In others, dissolution of cell wall in between the two gametangial brings about gametangial copulation. e.g., Rhizopus, Mucor.
- ☐ Spermatization: Here the uninucleate male gametes called spermatia are formed in special structures called spermogonia or pycnidia. The female gametangium is called as ascogonium which has a long neck called trichogyne. The spermatium attaches itself with the trichogyne and transfers the male nucleus, thus bringing about dikaryotisation. e.g., Puccinia graminis.

Somatogamy: In higher fungi there is reduction of sexuality to the maximum level. Here two hyphae of opposite strains are involved in fusion thus bringing about **dikaryotization**. e.g., Penicillium brefeldianum, Agaricus.

Clamp connection

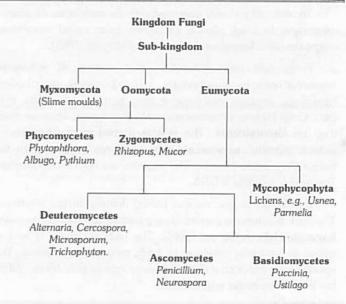

In Basidiomycetes, the dikaryotic cells divide by **clamp connections**. They were first observed by Hoffman (1856) who named it as '**Schnallenzellen**' (buckle-joints). A lateral pouch like outgrowth arises which projects downward like a hook. This pouch or **clamp** becomes almost parallel to the parent cell. The two nuclei now undergo conjugate division in such a way that one spindle lies parallel to the long axis of the cell and the other somewhat obliquely. As a result, one daughter nucleus enters into the clamp.

Heterothallism

Blakeslee, (1904) while working with Mucor sp. observed that in some species sexual union was possible between two hyphae of the same mycelium, in others it occurred between two hyphae derived from 'different' spores. He called the former phenomenon as **homothallism** and the later as **heterothallism**. Thus, the homothallic species are self-fertile whereas the heterothallic are self sterile. In heterothallic species the two 'thalli' are sexually incompatible. They are said to belong to opposite strains. Blakeslee designated them as + and - i.e., belonging to opposite strains or mating types. Bipolar heterothallism found in Mucor and Rhizopus.

Classification

The classification of fungi based on the characteristics of the life cycle involved like nature of somatic phase, kinds of asexual spores, kinds of sporangia, nature of the life cycle and presence or absence of perfect or sexual stage.

Important features of classes

- (1) Phycomycetes (Oomycetes/Algal fungi): It is also called lower fungi, mycelium is coenocytic. Hyphal wall may contain chitin or cellulose (e.g., Phytophthora). Asexual reproduction occurs with the help of conidio-sporangia. Under wet conditions they produce zoospores. Under dry conditions, the sporangia directly function as conidia. Zoospores have heterokont flagellation (one smooth, other tinsel). Sexual reproduction is oogamous. It occurs by gametangial contact where male nucleus enters the oogonium through a conjugation tube. The fertilized oogonium forms oospore. e.g., Saprolegnia, Albugo (Cystopus), Phytophthora, Phythium, Sclerospora, Peronospora, Plasmopara.
- (2) Zygomycetes (Conjugation fungi): Mycelium is coenocytic. Hyphal wall contains chitin or fungal cellulose. Motile stage is absent. Spores (Sporangiospores/Aplanospores) are borne inside sporangia. Sexual reproduction involve fusion of coenogametes through conjugation (Gametangial copulation). It produces a resting diploid Zygospore. On germination, each zygospore forms a germ sporangium at the tip of a hypha called promycelium e.g., Mucor, Rhizopus, Pilobolus, Abscidia, Saksenea.
- (3) Ascomycetes (Sac fungi): These are unicellular as well as multicellular fungi. In the latter, mycelium is septate. The asexual spores formed in chains are called conidia. The spores are formed exogenously, i.e., outside sporangium. They detach from the parent and form new mycelia. Sexual reproduction is through ascospores, which are formed endogenously (within the mycelium) in a sac like structure called ascus (pl. asci). Ascus arranged either in linear order (Neurospora) or unorderly (e.g., Yeast). The gametes involved in sexual reproduction are nonmotile compatible and are generally represented as + and -. The fusion of gametes is followed by reductional division that produces haploid ascospores.

UNIVERSAL BOOK DEPOT 1960

The fruiting body called **ascocarp**. Genus penicillium belong to this e.g., Erysiphe, Claviceps, Clan,

The ascocarp are of four types:

- (i) **Cleistothecium**: It is an ovoid or spherical fruiting body which remains completely closed e.g., Aspergillus. Penicillium.
- (ii) **Perithecium**: It is a flask shaped fruiting body which opens by a single pore called **ostiole**. e.g., Neurospora.
- (iii) **Apothecium :** It is a saucer-shaped fruiting body. The asci constitute the fertile zone called **hymenium** e.g., Peziza.
- (iv) Ascostroma: It is not a distinct fruiting body. It lacks its own well defined wall. The asci arise directly with a cavity (locule) of stroma. It is also called as pseudothecium e.g., Mycosphaerella.
- (4) Basidiomycetes (Club fungi): They are the most advanced fungi and best decomposers of wood. These are called club fungi because of a club shaped end of mycelium known as basidium. They have septate multinucleated mycelium. Septa possess central dolipores and lateral clamp connections. The sexual spores called basidiospores are generally four in number. They are produced outside the body (exogenous) unlike ascomycetes where they are endogenous. Two compatible nuclei fuse to form zygote, which undergoes meiosis and forms four basidiospores. The fruiting body containing basidia is a multicellular structure called basidiocarp. The common members are edible mushrooms (Agaricus), smut (Ustilago) and rust (Puccinia).
- (5) **Deuteromycetes (Fungi imperfecti)**: The group include all those fungi in which sexual or perfect stage is not known. Mycelium is made of septate hyphae. Asexual reproduction commonly occur by means of conidia. e.g., Alternaria solani, Fusarium, Gibberella, Collectrichum falcatum, Helminthosporium oryzae, Cercospora personata.

Economic importance

(1) Harmful aspects

Crop diseases : Several important crop plants are destroyed by fungal diseases. Some important ones are listed here under :

Table: 1.4-1 Fungal disease in plants

Disease	Causal organism
White rust of crucifers	Albugo candida or Cystopus candidus
Early blight of potato	Alternaria solani
Tikka disease of groundnut	Cercospora personata
Ergot disease of rye	Claviceps purpurea
Red rot of sugarcane	Colletotrichum falcatum

Powdery mildew of wheat Erysiphe graminis Powdery mildew of pea Erysiphe polygoni Leaf spot of oats Helminthosporium avenae Brown leaf spot of rice* Helminthosporium oryzae Covered smut of barley Ustilago hordei Loose smut of wheat Ustilago tritici, : Late blight of potato** Phytophthora infestans Downy mildew of grapes Plasmopara viticola Black rust of wheat Puccinia graminis-tritici Brown rust of wheat Puccinia recondita Yellow rust of wheat Puccinia striformis Damping off of seedlings Pythium sp. Wart disease of potato Synchytrium endobioticum Covered smut of jowar Sphacelotheca sorghii (Sorghum)

*Severe famine of Bengal (1943) which caused death of a large number of people was due to this disease.

**Famous famine of Ireland (1845) is associated with this disease which caused death of lakhs of people.

Diseases in human beings: Some important onces are:

Table: 1.4-2 Fungal disease in human

Disease	Causal organism	Place of infection
Athletes foot	Epidermophyton floccosum	Foot
Ring worm	Trichophyton sp., Microsporum sp.	Skin
Moniliasis	Candida albicans	Nails
Aspergillosis Aspergillus niger, A. flavus, A. terrus		Lungs
Torulosis	Cryptococcus neoformans	Lungs, CNS

Spoilage of food : Some forms like *Rhizopus, Mucor,* Aspergillus, *Cladosporium* grow on food articles and spoil them. *Cladosporium* grows even at a temperature of $-6^{\circ}C$.

Aflatoxins: They are produced mainly by Aspergillus flavus and A. parasiticus. They are well known for their carcinogenic effect. e.g., Aflatoxin B_1 , B_2 , M_1 , M_2 , G_1 , G_2 .

Poisonous fungi : Some fungi are extremely poisonous e.g., Amanita phalloides ('death cup'), A. verna and Boletus satanus. Forms like Coprinus, Psilocybe are less poisonous. The fungus Amanita phalloides produces toxins like α -amanitin, phalloidin etc. which are very poisonous.

Ergotism: The fungus causing 'ergot' disease of rye (Secale) is Cleviceps purpurea. It contains many poisonous alkaloids in their sclerotia. It causes poisoning in human beings. It's acute condition is called as 'St. Anthony's fire'.

Hallucinogenic drugs: The hallucinogenic drug LSD (Lysergic acid diethylamide) is extracted from *Cleviceps purpurea* as also from *Inocybe*. Besides, the mushroom *Amanita muscaria* is also hallucinogenic.

Rotting of wood: Rotting of wood is caused due to degradation of lignin and cellulose. It is brought about fungi like Polyporus sp., Fomes sp. and Ganoderma sp., Forms like Fusarium, Penicillium leave stains on the wood.

Allergies: Spores of *Mucor*, *Aspergillus*, *Penicillium*, *Puccinia* etc., present in the atmosphere cause allergies.

Deterioration of articles : Forms like Aspergillus, Cladosporium, Rhizopus, Chaetomium, Alternaria deteriorate cork, rubber, leather, textile and even plastics.

(2) Useful aspects

Food: Forms like Agaricus bisporus, Agaricus campestris, Podaxon, Prodaxis, Morchella esculenta, Lentinus edodes, Clavatia gigantia, Volvariella volvacea are edible. The yeast Saccharomyces cerevisiae is used for making 'yeast cake', when mixed with cereal flour, the yeasts produce a preparation called incaparina. The Single Cell Protein (SCP) obtained from yeasts, Penicillium, Fusarium etc. are used as substitute of protein food. Rhizopus oligosporus when processed with soyabeans yield a food preparation called 'tempeh'. It has high protein contents.

Organic acids: Several organic acids are commercially produced by fungi, some of which are given hereunder:

Table: 1.4-3 Fungi as a source of organic acids

Organic acids	Source
Citric acid	Aspergillus niger
Gallic acid	Penicillium glaucum
Gluconic acid	Aspergillus niger, Penicillum purpurogenum
Fumaric acid	Rhizopus stolonifer, Mucor sp.
Lactic acid	Rhizopus nodosus
Kojic acid	Aspergillus flavus
Oxalic acid	Aspergillus niger

Flavouring of food: Penicillium roquefortii and P. camemberti are employed for flavouring cheese.

Brewing and baking : Yeasts are generally used in bakeries and breweries. e.g., Saccharomyces cerevisiae.

Antibiotics: The antibiotics are chemicals produced by living organisms that kill other living organisms. The first known antibiotic is **penicillin** that was extracted from *Penicillium notatum* by A. Flemming, (1944). Raper (1952) also extracted the same antibiotic from *P. chrysogenum*. Besides, several other antibiotics have been extracted since then.

Table: 1.4-4 Fungi as a source of antibiotics

Antibiotics	Source
Griseofulvin	Penicillium griseofulvum
Cephalosporin	Acremonium sp.
Ramycin	Mucor ramannianus
Jawaharin	Aspergillus niger
Patulin/Clavicin	A. patulum/ A. clavatus
Fumigallin	Aspergillus fumigatus
Frequentin	Aspergillus cyclopium
Chloromycetin	Streptomyces venezualae

Other chemicals: Various chemicals have been obtained from different kinds of fungi. Yeast are good source of glycerol and enzymes like zymase, invertase and lipase. Cellulases are obtained from Aspergillus. Some alkaloids are also obtained from fungi e.g., Ergotinine, Ergotetrine and Ergobasine from Cleviceps purpurea. Gibberellins (plant hormones) are obtained from Gibberella fujikuroi. Another hormone, trisporic acid is obtained from Mucor mucedo.

Biological assays: The fungi can detect the presence of certain chemicals present in the medium even in traces e.g., Aspergillus niger for Mn, Pb, Zn, Cu, Mo etc.

Vitamins : Various vitamins have been obtained from different kind of fungi.

Table: 1.4-5 Fungi as source of vitamins

Vitamins	Source
Vitamin A	Rhodotorula gracilis
Vitamin B ₂	Eremothcium ashbyii
Thiamine B ₁	Saccharomyces cerevisiae
Riboflavin B ₂	Saccharomyces cerevisiae

In biological control: Soil inhabiting fungus *Trichoderma* kills *Pythium* fungus (root rot fungus). Similarly *Penicillium Vermiculatum* checks *Rhizoctonia solani*.

Many species of *Neurospora* have been used as convenient organisms for genital and biochemical studies. *Neurospora* is also known as *Drosophila* of plant kingdom.

Description of some important fungus

Rhizopus/Mucor

Habitat: They are cosmopolitan and saprophytic fungus, living on dead organic matter. Rhizopus stolonifer occur very frequently on moist bread, hence commonly called black bread mold Mucor is called dung mold. Both are called black mold or pin mold because of black coloured pin head like sporangia. Besides, it appears in the form of white cottony growth on moist fresh organic matter, jams, jellies, cheese, pickles, etc.

Structure: The vegetative body or thallus consists of well branched, aseptate and multinucleate (coenocytic) mycelium on the surface of substratum. The mature mycelium is distinguishable into three types of hyphae:

- (1) Stoloniferous hyphae (Stolons): These hyphae grow horizontly on the surface of substratum. They are relatively stout and less branched than other hyphae. Certain portions of the stolons called nodes, give out rhizoids and sporangiophores.
- (2) Rhizoidal hyphae: They arise in clusters from the lower side of each node and are repeatedly branched. The rhizoids penetrate the substratum and serve as anchors for the superficial mycelium. These hyphae secrete enzymes like amylase and maltase into the substratum and absorb the digested food.
- (3) **Sporangiophores**: They are erect, aerial, unbranched reproductive hyphae that arise in clusters from the upper side of each node. Each sporangiophore develops single terminal sporangium which is filled with spores. In *Mucor* there is no such distinction. In *Mucor*, the hyphae develop singly. There is no holdfast or apparant node. The hyphal wall is made up of chitin or fungus cellulose, a polymer of glucosamine $(C_8H_{13}O_5N)n$.

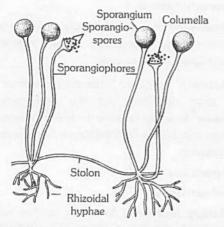

Fig: 1.4-1 Rhizopus – Habit sketch showing stolon, rhizoidal hyphae and sporangiophores

Reproduction : They reproduces by vegetative, asexual and sexual methods.

- (1) **Vegetative reproduction**: It takes place by fragmentation. If stolon breaks accidentally into small segments, each part grows into a new mycelium.
- (2) Asexual reproduction: It occurs by three types of non-motile mitospores, sporangiospores, chlamydospores and oidia.

Sporangiospores: The sporangiospores are also called **aplanospores**. They are thin walled, non-motile, multinucleate spores formed in a sporangium. A vertically growing mycelium acts as sporangiophore. Its tip now shows accumulation of food and nuclei. A septum now appears separating the **outer sporangium** from the **inner columella**. The sporangium dehisces irregularly due to collapse of columella and the spores are dispersed.

Chlamydospores: These are the perennating spores formed when the fungus starts facing dry conditions. The protoplasm of hyphae collects at certain places, rounds off accumulates a lot of food materials and develops thick wall to become chlamydospores.

Arthrospore or Oidia: In liquid, sugary and acidic pH medium the hyphae of Rhizopus and Mucor undergo septation and form small rounded reproductive cells called oidia. They multiply by budding like yeast. The budded condition is called torula stage. It takes part in alcoholic fermentation. On transfer to a suitable solid medium, each oidium forms a new mycelium.

(3) **Sexual reproduction :** Sexual reproduction takes place by conjugation between two multinucleate but single celled gametangia. The gametes are isogamous and non-motile.

The species of *Rhizopus* may be **heterothallic** (*R.stolonifer*) or **homothallic** (*R. sexualis*). But mostly heterothallic in both *Mucor* and *Rhizopus*. In homothallic species sexual union is brought about between two hyphae of the same mycelium whereas in heterothallic species it occurs between two hyphae derives from different compatible strains i.e., positive (+) and negative (-).

The two mycelial branches growing towards each other are called **progametangia**. Their tips become rich in food and nuclei. They enlarge and come in contact with each other. A septum is laid down separating the terminal **gametangium** from the proximal **suspensor**. The gametangium has dense cytoplasm and many nuclei whereas the suspensor has vacuolated cytoplasm with fewer nuclei. Each gametangium behaves as an coenogamete. The two gametangia fuse with each other. **Plasmogamy** is followed by pairing of nuclei of opposite strains. The unpaired nuclei degenerate. This is followed by **karyogamy**. The **zygospore** so formed develops a dark coloured thick wall and undergoes rest. It is also believed that karyogamy is delayed till the germination of zygospore.

On the arrival of favourable conditions the zygospore germinate. The outer wall ruptures and the inner protrudes out in the form of promycelium. The promycelium grows vertically upward and forms a terminal **germsporangium**. It is generally believed that meiosis occurs in the germ sporangium. Each diploid nucleus forms four haploid nuclei, of which three degenerate.

Occasionally, failure of gametangial copulation results in parthenogenous development of zygospores which are called **azygospore** (parthenospores).

Life cycle is haplobiontic.

Economic importance

- (1) **Spoilage of food**: Exposed bread and other food particles are spoiled by *Rhizopus*.
- (2) **Soft rot**: Rhizopus species attack sweet potato, apple and strawberry producing soft rot or leak disease. Germinating maize grains are also attacked.
- (3) Mucormycosis: Mucor pusillus and M. ramosissimus may attack internal human organs, including lungs alimentary canal and nervous system.
- (4) Fermented foods: Temph (a solid food from soyabean) and sufu (chinese cheese) are prepared with the help of Rhizopus and Mucor respectively.
- (5) **Chemicals**: Citric acid prepared by *Mucor* from molasses, fumaric acid and cortisone by *Rhizopus stolonifer*, Lactic acid by *R. stolonifer* and *R. nodosus* and alcohol by *R. oryzae* and *M. javanicus*.

Yeast

Habitat: Yeast is a saprophytic fungus of ascomycetes, found on substratum which is rich in sugars *e.g.*, sugarcane, juice, fruits (palms, grapes), milk etc. Some species are found on animal excreta.

Structure: Yeast was first described by Anton Van Leeuwenhoek in 1680. Yeast are nonmycelial or unicellular, which is very small and either spherical or oval in shape. However, under favourable conditions they grow rapidly and form **false mycelium** or **pseudomycelium**. Individual cells are colourless but the colonies may appear white, red, brown, creamy or yellow. The single cell is about $10~\mu m$ in diameter. The cell is surrounded by a rigid cell wall which is having proteins (7.8%), lipids (8.5 – 13.5%), Chitin (1 - 2%). Besides, there are 2 important polysaccharides glucan (30 - 35%) and mannan (about 30%).

Yeasts are facultative aerobes i.e., they are anaerobes but can also survive under aerobic conditions and respire aerobically as well. The yeast cells secrete extracellular enzyme **zymase** which converts complex sugars into simple soluble sugars that can easily be assimilated.

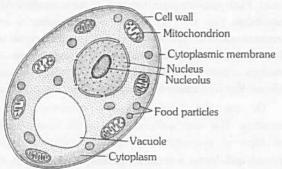

Fig: 1.4-2 Electron micrograph of single yeast cell

Reproduction: Yeast reproduces by vegetative or asexual and sexual methods.

(1) **Vegetative reproduction**: Yeast reproduce vegetatively either by budding or by fission.

By budding: It is the common method of reproduction in yeasts (e.g., Saccharomyces) under favourable conditions (i.e., when growing in sugar solution). During this process a small bud like out growth appears at one end of the parent cell which gradually enlarges in size (unequal division of cytoplasm takes place) The nucleus enlarges and divides amitotically into two daughter nuclei.

By fission: It is a common method of reproduction in yeasts (e.g., Schizosaccharomyces). During fission the parent cell elongates and its nucleus divides into two daughter nuclei. The two nuclei separate apart. It is followed by a transverse cytokinesis by formation of a transverse septum which develops centripetally. The two cells separate apart and behave as uninucleate vegetative thalli.

(2) Sexual reproduction: Sexual reproduction in yeast takes place during unfavourable conditions, particularly when there is less amount of food.

The sex organs are not formed in yeasts and the sexual fusion occurs between the two haploid vegetative cells or two ascospores which behave as gametes. The two fusing gametes are haploid and may be **isogamous** or **anisogamous**. Such kind of sexual reproduction is called **gametic copulation**. It is the best example of **hologamy** *i.e.*, the entire vegetative thallus is transformed into reproductive body. The sexual fusion leads to the formation of diploid zygote. The zygote behaves as an ascus and forms 4-8 haploid ascospores after meioses. These liberate and function as vegetative cells.

Guilliermond (1940) has recognised three types of life cycle in yeasts.

- Haplobiontic life cycle: This type of life cycle is common in Schizosaccharomyces octosporous, a homothallic species.
- (2) **Diplobiontic life cycle**: This type of life cycle is found in *Saccharomyces ludwigii*.
- (3) Haplodiplobiontic life cycle: This type of cycle is found in Saccharomyces cerevisiae in which haploid and diploid both types of generations are found.

In addition to above, in *Schizosaccharomyces pombe*, two adjoining sister cells fuse and this phenomenon is called **adelphogamy**. In some yeasts e.g., *Debaryomyces*, the mother and daughter cells fuse to form the zygote and this phenomenon is called **pedogamy**.

Economic importance

Useful activities

(1) **Baking industry**: Yeast are used in manufacture of bread. Kneaded flour is mixed with yeast and allowed to ferment. Yeast convert starch into sugars and sugar into CO_2 and alcohol

UNIVERSAL BOOK DEPOT 1960

with help of enzyme zymase, CO_2 is released when effervescence takes place due to which bread become spongy and gets swollened and is of light weight.

(2) **Brewing industry**: Brewer's yeast or Baker's yeast is Saccharomyces cerevisiae and wine yeast is Saccharomyces ellipsoidens. They perform alcoholic fermentation.

$$C_{6}H_{12}O_{6} \xrightarrow[Slucos\,e]{Yeast} C_{2}H_{5}OH + 2CO_{2}$$

(3) **Food yeast**: Yeast from brewing industry is harvested and used as food yeast. It is rich in protein and vitamins-B (Riboflavin). Special food yeasts are Torulopsis (protein), Endomyces (fat) and Cryptococus (both).

Harmful activities

- (1) Fermentation of fruits and fruit juices by yeast cells makes their taste unpleasent.
- (2) Parasitic species of yeast like *Nematospora* causes diseases in tomato, cotton and bean.
- (3) Parasitic yeast cause diseases in human beings (e.g., cryptococcosis, blastomycosis and torulosis).

Albugo

Habitat: Albugo is a member of phycomycetes. It is an obligate parasite and grows in the intercellular spaces of host tissues. It is parasitic mainly on the members of families Cruciferae, Compositae, Amaranthaceae and Convolvulaceae, The disease caused by this fungus is known as **white rust** or **white blisters**.

The most common and well known species is Albugo candida which attacks the members of the mustard family (Cruciferae). It is commonly found on **Capsella bursa pastoris** (Shepherd's purse) and occasionally on radish, mustard, cabbage, cauliflower, etc. The reserve food is oil and glycogen.

Structure: The plant body of the fungus is mycelial and eucarpic. The mycelium is intercellular, branched, aseptate and multinucleate (coenocytic). The mycelium produces finger like or globular haustoria which enter into the host cells to absorb the food material. The mycelial wall is made up of cellulose-glucan.

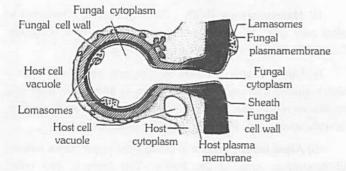

Fig: 1.4-3 Albugo – Ultra structure of haustorium (diagrammatic)

Reproduction : The fungus *Albugo* reproduces asexually as well as sexually.

(1) Asexual reproduction: Asexual reproduction takes place by the formation of sporangia or conidia. The fungal mycelium collects below the host epidermis and forms sporangiophores (conidiophores). These are club-shaped and multinucleate. The sporangiophores cut sporangia in basipetal manner, that is, the oldest and first formed are at the top and the youngest and last formed are at the base.

If water is available sporangia forms about 4 - 12 (usually eight) zoospores within two minutes of their formation. The zoospores are kidney shaped and laterally biflagellate (unequal).

If water is not available, the sporangia germinate directly by forming germ tubes.

(2) Sexual reproduction: The sexual reproduction is oogamous type and takes place with the help of antheridia and oogonia. The antheridia and oogonia are multinucleate in the beginning but become uninucleate by disorganization of nuclei. The antheridia are club-shaped and the oogonia are globular. Both sex organs develop terminally on the hyphae. There is a single egg (oosphere) surrounded by periplasm. At the time of fertilization, a receptive papilla develops on one side of the oogonium through which the fertilization tube enters into the oogonium. Inside the oogonium the male nucleus fuses with the egg nucleus. The diploid zygote develops a warty wall and becomes the oospore. The diploid nucleus undergoes meiosis, followed by several mitotic divisions. After a period of rest, the oospore germinates and produces reniform, biflagellate (dissimilar and laterally) zoospores. The zoopores are first released into a vesicle and then to the outside. They swim for some time, encyst and then germinate to form germ tubes. Most part of the life cycle of Albugo is gametophytic. The sporophytic phase is limited only to the oospore stage.

Aspergillus(Psalliota)

- (1) Aspergillus is the common laboratory weed which also grows on a number of food stuffs.
- (2) A oryzae is used to prepare alcohol by saccharification of rice starch.
 - (3) A. niger is used to produce citric acid from molasses.
- (4) A. oryzae and A niger are also used for production of various enzymes.
- (5) A. flavus is a serious health hazard because of their toxic effect on food caused by secretion of 'aflatoxin' in contaminated food.
- (6) Some species cause aspergillosis, a disease a man and animals.

Agaricus

- Agaricus is a group of macrofungi that grows in rich organic matter. They are commonly known as mushrooms.
- (2) Habitat: They grow in rich organic soil. During rainy season they are abundantly found in shady places growing on rotten logs of tree trunks.
- (3) **Structure**: The mature plant body of the fungus is divided into two parts:

- (i) Vegetative mycelium: The vegetative mycelium runs hidden in soil. This perrenating stage after somatogamy becomes dikaryotic called as rhizomorph.
- (ii) Fruit body: It is formed during rainy season. The above ground part of the fungus is generally reffered to as sporophore or basidiocarp. It is the most conspicuous part of the fungus. The binucleate mycelium of the soil gives rise to the sporophore. The sporphore is divided into two parts.
- □ Stipe or stalk : It is the basal part of the sporophore consisting of cylindrical fleshy body having pinkish white colour.
- □ Pileus or cap: It is umbrella shaped. It is formed by swelling of the tip of stipe. On the ventral side develops hymenial layers of gills from the centre towards periphery.

Internally gill is also composed of pseudoparenchymatous tissue distinguished into:

(i) Trama : The central part

(ii) Sub-hymenium: Located on both sides of trama and is sterile

(iii) Hymenium

: Fertile layers bearing basidia

- (4) Reproduction: Only type of reproduction is somatogamy between two negative and positive strains of somatic hyphae which results in formation of dikaryotic rhizomorph. Rhizomorph forms fruit body which bears basidia. Each basidium has two nuclei of different strains which undergo fusion forming diploid nucleus. This nucleus undergoes meiosis to form four nuclei two of +ve and two of -ve strain. The nuclei are pushed into four finger like projections called as sterigmata. Nuclei are pushed into each sterigmata so as to form basidiospores. They are thrown on the substratum where they germinate to haploid vegetative hyphae.
- (5) Economic importance of Agaricus: A bisporus and campestris are edible.

Lichens

The term lichen was first given by Theophrastus for superficial growth on bark of Olea europea (olive) tree. A lichen is structurally organised entity consisting of the permanent association of a fungus and an alga. The fungal component of a lichen is called mycobiont (mostly ascomycetes) and the algal component is called phycobiont (mostly blue-green alga). The fungus provides the structural covering that protects alga from unfavourable conditions, i.e., drought, heat etc. It also traps moisture from the atmosphere and anchors the lichens to a substrate. The algaprepares organic food (e.g., mannitol) by the process of photosynthesis from carbon dioxide. If the algal component is a cyanobacterium (blue-green alga), it fixes atmospheric nitrogen in addition to preparation of food. The relationship between the two is that of consortium, symbiosis or mutualism. Crombie (1885) gave the master and slave hypothesis for this association (also called husband and wife association) and in this association fungal partner is having upper hand. It is also known as helotism. Micheli (1729) describe 300 species of lichens. Dual nature of lichen was studied by Schwendener (1897). Ahmadjian (1963)

considers fungus to be a controlled parasite. The phenomenon of controlled parasitism is called helotism. The study of lichen is called lichenology.

Habitat: Lichens are cosmopolitan in distribution. Their growth is very slow. Some lichens growing in arctic regions are believed to be 4500 year old. The lichens which grow on stones are called saxicolous (e.g., Dermatocarpon) and those growing on barks of tree are called corticolous (e.g., Usnea, Parmelia, Graphis). Some lichen developing on wood are called lignocolous (e.g., Cyphelium) and those growing on soil are called terricolous (e.g., Cladonia, Lecidea). A few lichens are aquatic (e.g., Peltigera, Verrucaria margacea). The lichens generally do not grow near smoky industrial areas where atmosphere is polluted. Cladonia rangiferina, commonly known as reindeer-moss grows luxuriantly in tundra region and form the food of animals like the reindeer and caribou (musk ox).

Classification: Hole (1967) divided lichens into 3 classes:

(1) Ascolichens: When fungal partner belongs to ascomycetes. Most lichens are ascolichens. Ascolichens are further divided into:

Gymnocarpeae: Fruiting body is apothecium.

Pyrenocarpeae: Fruiting body is perithecium.

- (2) Basidiolichen: When the fungal partner belongs to basidiomycetes.
- (3) Lichen Imperfecti: When the fungal component belongs to fungi imperfecti.

Structure

- (1) External structure: The lichens vary in their size and shape. However, three main types are recognised on the basis of their habit, growth, form and mode of occurrence.
- (i) Crustose or Crustaceous lichens: These lichens occur as crust over rocks, soil or tree barks, e.g., Graphis, Haematomma.
- (ii) Foliose or Foliaceous lichens (Leafy lichens): They are leaf like lobed structure which are attached to substratum by rhizoid like organs, e.g., Parmelia, Paltigera.
- (iii) Fructicose or Filamentous lichens : They are branched shruby lichens but small base e.g., Cladonia, Usnea.
- (2) Internal structure: The bulk portion of lichen thallus is formed by fungal partner. The alga constitutes about 5% of the lichen body. Internally the lichens are of two types:
- (i) Homoiomerous thalli: Algal cells and fungal hyphae are uniformly dispersed throughout the thallus, e.g., Collema.
- (ii) Heteromerous thalli: The algal cells are restricted to algal zone only. In these forms fungal component is dominant. Usually the heteromerous thalli show 4 distinct zones.
- (a) Upper cortex: Formed by compactly interwoven hyphae either without interspaces between them or interspaces filled with gelatinous substances. A cuticle like layer is present on the surface. In some species e.g., Parmelia breathing pores are present.
- (b) Algal layer: Present just below the upper cortex forming photosynthetic zone of the thallus. This layer is also called gonidial layer.
- (c) Medulla: Occurs nearly in the middle of the thallus beneath the algal layer, the hyphae are loosely interwoven in this layer, Parmelia, Graphis.

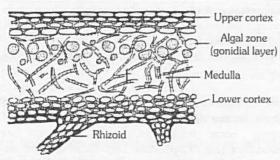

Fig: 1.4-4 Transverse section of a foliose lichen

(d) Lower cortex: Comprising of closely packed dark coloured hyphae rhizoids arise from this layer.

Special structures and Propagules : The following specialized structures and propagules are associated with lichen thalli :

- (1) Breathing pores: The upper surface of some lichens, particularly the foliose lichens is provided with pores. Here the fungal hyphae are loosely arranged. They help in aeration.
- (2) Cyphellae: Loosely arranged areas in lower cortex are cyphellae and these also help in gaseous exchange. Cyphellae are analogous to stomata of higher plants.
- (3) Cephalodia: These are gall like outgrowths present on the upper surface of the thallus. They are distinguishable into cortex and medulla with similar fungal but different algal components from that of the main thallus. Lichens having two algal and one fungal partner are called diphycophilous. The cephalodia are meant for retaining moisture e.g, Peltigera.
- (4) **Isidia**: These are coral like, simple or branched outgrowths present on the upper surface of the thallus. They have the same algae and fungal component as that of the main thallus. They help in photosynthesis as also in vegetative propagation e.g., Parmelia, Peltigera.
- (5) **Soredia**: It is a powdery mass comprising both algal and fungal components formed in a postule like structure called **soralium**. The soralia arise from the algal zone lying just below the upper cortex *e.g.*, *Physia*, *Parmelia*.

Reproduction: Lichens reproduce both by asexual and sexual methods.

(1) Asexual reproduction

Fragmentation: The main thallus breaks into small pieces which grow as independent thalli.

Rejuvenation: Plants like *Cladonia* show this unique phenomenon. It becomes young again. The older parts of the thallus die whereas the young branches continue to grow.

Conidia: In serveral lichens the fungal component forms conidia on conidiophores. They form new fungal mycelium which with suitable algal component form the lichen.

Pycniospores : The conidia formed in a flask shaped structures lying embedded in the thallus (pycnidia) are called as pycniospores. The pycniospores form new fungal mycelium which consitute the lichen on coming in contact with suitable algal component.

(2) Sexual reproduction: Sexual reproduction in lichen is performed only or mainly by its fungal component. So, the structure of the reproductive organs is dependent upon the type of their fungal partner.

Economic importance

- (1) Pioneer of vegetation: Lichens are considered as pioneers in initiating a plant succession on rocks. These are the first plant group which play an important role in the formation of the soil. So lichens are called as formers of nature or soil builders.
- (2) **Food and Fodder**: Reindeer moss (Cladonia rangiferina) of the arctic region is used as food for reindeer and cattle. Iceland moss (Cetraria icelandica) is ground up and mixed with wheat and made into cakes in Iceland. Rock tripe (Umbillicaria) has been eaten by travellers when they face starvation in arctic regions.
- (3) **Medicinal uses**: Dog lichen (*Peltigera canina*) was used as medicine for hydrophobia in ancient days and Lungwort (*Lobaria pulmonaria*) was used for the diseases of lungs. Usnic acid obtained from *Usnea* (old man's beard) and *Cladonia* sp. is used as broad spectrum antibiotic. It is effective against gram positive bacteria. *Lobaria pulmonaria*, *Cetraria icelandica* are used in respiratory diseases particularly T.B., *Roccella montagnei* in angina, *Parmelia sexatilis* in epilepsy and *Usnea barbata* in urinary troubles.
- (4) In perfumery: Ramalina and Evernia, having sweet scented thalli, are used in the preparation of **Dhup**, **Havan** Samagri and soap. Perfumes are extracted from Evernia prunastri and Lobaria pulmonaria.
- (5) In tanning and dying: Lichens like Cetraria icelandica and Labaria pulmonaria are used in tanning. A red dye is obtained from Ochrolechia sp. whereas Parmelia sp. yield a brown dye. Litmus used as acid-base indicator is obtained from Roccella montagnei and Lasallia pustulata. An orchill dye is obtained from Roccella and Lecanara which is purified as orcein and used as a biological stain.
- (6) In brewing and distilling: The lichens contain carbohydrates in the form of lichenin. Cetraria islandica and Cladonia rangiferina (yield upto 66% of the polysaccharides) are used to obtain alcohol in Sweden and Russia.
- (7) Indicators of air pollution: Lichens are very sensitive to SO_2 and grow only in SO_2 free atmosphere. So lichens like Usnea are used as indicators of air SO_2 pollution.
- (8) As poison: Some lichens are poisonous also such as Letharia vulpina due to vulpinic acid, Cetraria juniperina due to pinastrinic acid, Parmelia molliuscula due to selenium, Xanthoria parietina due to beryllium and Everina furfuracea due to chlorine.
- (9) Other uses: Some lichen yield important chemicals e.g., salazinic acid (Ramalina siliquosa), Lecanoric acid (Parmelia subrudecta) and squamatic acid (Cladonia crispata) etc. In hot season, Usnea gets dry and becomes highly inflammable. It easily catches fire and causes forest fires.

Mycorrhizae

The term 'mycorrhizae' was coined by Frank (1885). It is an association between a fungus and the root of a higher plant e.g. Pine, Birch, Eucalyptus, Ficus etc. The actively growing roots of higher plants get infected by fungi. As a result, the roots are modified (i.e., become tuberous, nodulated, coralloid, etc.) to accommodate fungi. The root cells and fungi directly transmit nutrient substances to each other. Mycorrhiza is an example of symbiosis or mutualism.

Types of mycorrhizae : Mycorrhizae are classified into three categories :

- (1) Ectotrophic mycorrhiza: It occurs only in about 3% of plant species, majority of which are forest trees, viz. pines, spurs, firs, oaks, beeches, birches, eucalyptus etc. The fungus partner is commonly a basidomycetes. In this type of mycorrhizae, the fungus completely encloses the rootlet in a sheath or mantle of tissue formed of compact hyphal cells and penetrates only between the cells of root cortex. The ectomycorrhizal fungus cannot exist saprotrophically in nature without a plant host association. Such roots are devoid of root hair, root cap and may become unforked bifurcate, nodular or coralloid.
- (2) Endotrophic mycorrhiza: In this kind of mycorrhizae the fungus does not form an external mantle but lives within the root. The endomycorrhizae are further divided into three groups:
- (i) **Ericaceous mycorrhizae**: The fungus forms dense intracellular coils in the outer cortical cells.
- (ii) Orchidaceous mycorrhizae: These are associated with orchid roots. The fungus forms association from the time when the orchid seeds germinate.
- (iii) Vesicular-arbuscular mycorrhizae (VAM): The fungi of this group mostly belong to zygomycetes. This type is significant in agriculture because it occurs in a large number of crop plants. The fungal hyphae develop some special organs, called vesicles and arbuscules, within the root cortical cells.
- (3) Ectoendotrophic mycorrhiza: This type of mycorrhizas sharing characteristics of both ecto and endotrophic mycorrhizas. The fungus forms a hyphal mantle and Hartig net as do the ectotrophic mycorrhiza and also establish haustoria and hyphae coils in the epidermal and cortical cells, like the ectorophic mycorrhizas. The external hyphae deliver organic compounds absorbed from the humus to the root cells. One of the best studied examples of ectoendotrophic mycorrhizas is the mycorrhiza of Monotrapa indica, the Indian pine.

Advantages of mycorrhizal association

- (1) The fungal hyphae increase a plant's uptake of certain nutrients from the soil, particularly phosphorus, copper, zinc, nitrogen and potassium.
- (2) The mycorrhizal hyphae permeate the soil and help the absorption of water by host more efficiently.
- (3) The mycorrhizal plants need less fertilizer and can even grow better on the infertile soils. They withstand high doses of heavy metals and acid rain pollution.
- (4) The fungi produce various growth promoting substances which help the plants to grow better.
- (5) Due to mycorrhizal association, the higher plants develop resistance to soil borne diseases (due to phytolaxins released by fungi), drought resistance and tolerate salinity, pH and temperature extremes.

Tips & Tricks

- Poisonous mushrooms like Amanita are commonly called Toad stools.
- Benicillium is known as blue mould.
- Father of Indian mycology and Plant pathology: E.J. Butler.
- Smallest fungus: Yeast with a size of 3-15 $\mu m \times 2$ -10 μm .
- Nitrogen fixing fungi: Some species of Rhodotorula and Saccharomyces.
- Fungi inhabiting wood are known as epixylic.
- Autoecious fungus completes its life cycle on one host e.g., coffee rust (Hameilia). Heteroecious fungi require two hosts to complete their life cycle e.g., Puccinia (wheat rust).
- Fungi grow on tree are called as lignicolous fungi (Polyporus).
- Keratimorphic fungi appear on nails, feathers, hairs, hoofs.
- Biotrophic parasite (Gaumann, 1946). Absorbs nutrients from living host/cells.
- Nacrotrophic parasite (Gaumann, 1946). Kills host cells for obtaining nourishment.
- Species of *Morchella* are commonly known as 'morels', 'sponge mushrooms' or 'gucchi'.
- Most suitable temperature for growth of mushrooms is 30 to 37° C.
- Bioactive molecule, cyclosporine A, that is used as an immunosuppressive agent in organ-transplant patients, is produced by the fungus *Trichoderma polysporum*.

- The species of Polyporus are commonly called 'bracket fungi' or 'self fungi'.
- Phytoalexin are secreted by plants in response to fungal reactions. They are generally phenolic compound.
- Largest fungus is 'Giant puffball'.
- Dolipore septum: In Basidiomycetes, the septum becomes barrel shaped around a central pore. Dolipore septum may be surrounded by pore cap.
- Guinea pig of plant kingdom is Aspergillus flavus.
- Biobleaching: Fungus Phanerochaele chrysosporium can bleach paper pulp better than bleaching power.
- Mycena is a fungus that produces latex.
- Parasexuality in fungi was first described by G.Pontecorva and Ropers (1952) in Aspergillus nidulans.

Ordinary Thinking

Objective Questions

Fungi (General)

- The term 'fungus' was coined by
 - (a) Gaspard Bauhin
- (b) De Bary
- (c) E.J. Butler
- (d) Sadasivan
- Who among the following is given the honour of "Father of Modern Mycology"
 - (a) Stanley
- (b) Bawden
- (c) De Bary
- (d) Micheli
- Mycology (Mycetology) is a branch which deals with the study of [AMU (Med.) 1998; KCET 2000]
 - (a) Viruses
- (b) Algae
- (c) Bacteria
- (d) Fungi
- 4. Which of the following antibiotic is active against fungus
 [Odisha JEE 2008]
 - (a) Streptomycin
- (b) Polyenes
- (c) Tetracycline
- (d) Neomycin
- 5. Basidiospores are borne on the tip of [Odisha JEE 2008]
 - (a) Mycelium
- (b) Ascocarp
- (c) Flagella
- (d) Aplanospore
- The highest number of species in the world is represented by [CBSE PMT (Pre.) 2012; NEET 2013]
 - (a) Fungi
- (b) Mosses
- (c) Lichens
- (d) Algae
- Which one of the following matches is correct

[AIPMT (Cancelled) 2015

(a)	a) Alternaria Sexual reproduction absent		reproduction		Deuteromycetes
(b)	Mucor	Reproduction by Conjugation	Ascomycetes		
(c)	Agaricus	Parasitic fungus	Basidiomycetes		
(d) Phytopht A		Aseptate mycelium	Basidiomycetes		

 A group of fungi with septate mycelium in which sexual reproduction is either unknown or lacking are classified under

[NCERT; Pb. PMT 2000; JIPMER 2002; AFMC 2010]

- (a) Phycomycetes
- (b) Deuteromycetes
- (c) Ascomycetes
- (d) Basidiomycetes
- Fungal spores produced asexually at the tips of hyphae are called [AFMC 2005]
 - (a) Sporangiophores
- (b) Anthospores
- (c) Conidiophores
- (d) Meiospores
- 10. Match column I with column II and select the correct option

Column I (Kingdom)		Column II (Class)		
A.	Morels	1.	Deuteromycetes	
B.	Smut	2.	Ascomycetes	
C.	Bread mould	3.	Basidiomycetes	
D.	Imperfect fungi	4.	Phycomycetes	

[KCET 2007; Kerala PMT 2011; AIPMT 2015]

- (a) A-3, B-4, C-1, D-2
- (b) A-2, B-3, C-4, D-1
- (c) A-4, B-1, C-2, D-3
- (d) A-3, B-4, C-2, D-1
- (e) A-2, B-1, C-4, D-3
- 11. All fungi can be called as

[CBSE PMT 1993; CMC Vellore 1993; MP PMT 2000]

- (a) Heterotrophs
- (b) Autotrophs
- (c) Saprophytes
- (d) Parasites
- Which of the following does not contain chlorophyll
 - (a) Fungi
- (b) Algae
- (c) Bryophyta
- (d) Pteridophyta
- 13. Which of the following is famous mycologist of India
 - (a) P. Maheshwari
- (b) M.O.P. Iyengar
- (c) K. Sharma
- (d) Sadasivan
- 14. Who gave the parasitic nature of fungus in plants
 - (a) Pasteur
- (b) Anton De Bary
- (c) Robert Koch
- (d) J.F. Kuhn
- Thread like filaments of fungi are known as

[NCERT; Manipal 1995]

- (a) Conidia
- (b) Mycorrhiza
- (c) Sporangium
- (d) Hyphae
- In 1943 the causal organism and host of Bengal famine was [EAMCET 1995; BHU 1995, 2008]
 - (a) Wheat rust by Puccinia
 - (b) Blast of rice by Pyricularia oruzae
 - (c) Blast of rice by Xanthomonas oryzae
 - (d) Brown leaf spot of rice by Helminthosporium oryzae
- Destruction of 50% maize plants in USA (1970) due to infection of
 - (a) Hemileia vastratrix
 - (b) Helminthosporium oryzae

Choose the wrong statements

- (c) Claviceps purpurea
- (d) Ustilago maydis
- [AIPMT 2015]
- (a) Neurospora is used in the study of biochemical genetics
- (b) Morels and truffles are poisnous mushrooms
- (c) Yeast is unicellular and useful in fermentation
- (d) Penicillium is multicellular and produces antibiotics

19.	Which one of the following has haplontic life cycle [CBSE PMT 2009]	32.	Septum in eumycota fungi, bearing a complex pore is designated as a [BHU 2002]
	(a) Funaria (b) Polytrichum		(a) Coenocyte (b) Septate hypha
DATE:	(c) Ustilago (d) Wheat		(c) Dolipore septum (d) Secondary simple pore
20.	The following is an example of saprophytes [KCET 1998] (a) Mushroom (b) Lichen	33.	Which of the following secretes toxins during storage conditions of crop plants [CBSE PMT 2002]
	(c) Unicellular algae (d) Ferns		(a) Fusarium (b) Pencillium
21.	The cell wall of fungi is made up of [NCERT;		(c) Aspergillus (d) Colletotrichum
	RPMT 1997, 99; CPMT 1998, 2009; MP PMT 2001; Odisha JEE 2004; NEET (Phase-I) 2016]	34.	Which of the following produces spores, but lacks vascular
	(a) Chitin (b) Cellulose		
	(c) Pectin (d) Suberin		(a) Pteridophytes (b) Gymnosperms
22.	Which one is the wrong pairing for the disease and its causal organism [CBSE PMT 2009]		(c) Fungi (d) Dicots
	(a) Late blight of potato – Alternaria solani	35.	The hyphae of Aspergillus are [AFMC 2002]
	(b) Black rust of wheat – Puccinia graminis		(a) Aseptate and multinucleate
	(c) Loose smut of wheat – Ustilago nuda		(b) Septate and multinucleate
	(d) Root-knot of vegetables-Meloidogyne sp		(c) Aseptate and uninucleate
23.	Facultative saprophyte is		(d) Septate and uninucleate
	(a) A parasite which can live as a saprophyte	36.	
	(b) Always a parasite		[Odisha JEE 2010; BHU 2012]
	(c) Always a saprophyte		(a) Endospore (b) Gametangia
. 2562	(d) May acquire parasitic mode of life		(c) Exospores (d) Conidiospore
24.	Which of the following is not correctly matched [AIIMS 1998]	37.	Gametangial copulation (conjugation) is common in
	(a) Root knot disease – Meloidogyne javanica		(a) Zygomycetes (b) Ascomycetes
	(b) Smut of bajra – Tolysporium penicillariae		(c) Phycomycetes (d) Deuteromycetes
	(c) Covered smut of barley – Ustilago nuda	38.	Dikaryon formation is characteristic of
	(d) Late blight of potato – Phytophthora infestans		(a) Ascomycetes and basidiomycetes
25.	The disease of potato responsible for famous famine of		(b) Phycomycetes and basidiomycetes
20.	Europe was caused by or late blight of potato is caused by		(c) Ascomycetes and phycomycetes
	[RPMT 1997; CPMT 2000; BVP 2000;		(d) Phycomycetes and zygomycetes
	HPMT 2005; BHU 2006; DPMT 2007]	39.	
	(a) Colletotrichum falcatum (b) Phytophthora infestans	37.	(a) Two haploid cells including their nuclei
145.52	(c) Potato mosiac virus (d) Alternaria solani		(b) Two haploid cells without nuclear fusion
26.	During the process of decomposition in which stage		
	complex organic matter convert into inorganic ions and salts		(c) Sperm and egg
	by fungi [GUJCET 2015] (a) Mineralization (b) Catabolism		(d) Sperm and two polar nuclei
	(c) Fragmentation (d) All of the above	40.	
27.	When fungi feed on dead organic matter, they are known as		[CBSE PMT 2008]
~	[CPMT 1999]		(a) Pseudomonas (b) Saccharomyces
	(a) Dimorphic (b) Parasites	7070	(c) Pythium (d) Xanthomonas
	(c) Saprophytes (d) None of these	41.	
28.	According to their modes of nutrition, the fungi are classified		[AMU (Med.) 1996; Chd. CET 1997
	into [CBSE PMT 2000]		(a) $(C_{22}H_{54}N_4O_{21})_n$ (b) $(C_{21}H_{54}N_4O_{22})_n$
	(a) One category (b) Three categories		(c) $(C_{22}H_{54}N_4O_{13})_n$ (d) $(C_{22}H_{24}N_4O_{21})_n$
	(c) Four categories (d) Six categories	42.	
29.			(a) Two haploid nuclei
			(b) Diploid zygotes
	(a) Zygomycota (b) Ascomycota (c) Deuteromycota (d) Basidiomycota		(c) Two similar nuclei
30.	1 11 DATE DATE 0000 101		(d) Two dissimilar haploid nuclei
50.	(a) Bacteria (b) Viruses	43.	
	(c) Fungi (d) Nematodes		(a) Ascomycetes (b) Basidiomycetes
31.			(c) Phycomycetes (d) Deuteromycetes
31.	[JIPMER 2002]	44.	. The fungus that may cause disease in human beings is
	(a) Cabbage (b) Potato		(a) Puccinia (b) Aspergillus
	(c) Pea (d) Groundnut		(c) Cystopus (d) Rhizopus

Pill	4,6	22	-		-
U	WVI	RS	AL		
D/	nny	DE	pn	T 01	080

[RPMT 2002]

Which of the following is not of fungal origin

[Odisha JEE 2010]

- (a) Calvacin
- (b) Citric acid
- (c) Tetracycline
- (d) Ergotamine
- 46. Covered smut of Sorghum is caused by
- [BHU 2002]
- (a) Sphacelotheca cruenta
- (b) Sphacelotheca sorghii
- (c) Sphacelotheca reiliana
- (d) Tolyposporium ehrenbergii
- 47. The fungus used for the commercial production of SCP is

[Kerala PMT 2009]

- (a) Pentadiplandra brazzeana
- (b) Fusarium graminearum
- (c) Brassica napus
- (d) Bacillus thuringiensis
- (e) Phytophthora infestans
- 48. Which of the following statement is true about fungi imperfecti [Odisha JEE 2008; BHU 2008]
 - (a) They do not have sexual phase
 - (b) They include species that prey only on nematodes
 - (c) They include toadstools, puffballs and stink horns
 - (d) They include Aspergillus, the fungus used to make soya sauce
- Fungus used in genetic experiments is [NCERT; RPMT 1998]
 - (a) Rhizopus
- (b) Mucor
- (c) Neurospora
- (d) Claviceps
- 50. The fungus which grows on dung is called [MP PMT 2010, 12]
 - (a) Humicolous
- (b) Lignicolous
- (c) Coprophilous (d) Fungicolous
- 51. Match column I with column II and choose the right option

Column I		Column II		
A.	Rhizopus	1.	Ascomycetes	
B.	Penicillium	2.	Basidiomycetes	
C.	Ustilago	3.	Deuteromycetes	
D.	Alternaria	4.	Zygomycetes	

[CPMT 1995; Pb. PMT 1999; BVP 2000; RPMT 2005; Kerala PMT 2010]

- (a) A-4, B-3, C-1, D-2
- (b) A-2, B-3, C-4, D-1
- (c) A-4, B-1, C-2, D-3
- (d) A-3, B-4, C-2, D-1
- (e) A-2, B-1, C-4, D-3
- 52. A coprophillous fungus is

[JIPMER 2000]

- (a) Trichoderma
- (b) Pilobolus
- (c) Fusarium
- (d) Humicola
- 53. Fungal hyphae are able to penetrate the host with the help of

[CBSE PMT 2001]

- (a) Mechanical pressure
- (b) Softening by enzymes
- (c) Both (a) and (b)
- (d) Suckers and hooks
- 54. Fungi differ from algae in being
 - (a) Coenocytic
 - (b) Without motile gametes
 - (c) Without unicellular forms
 - (d) Without chlorophyll and possessing chitinised wall

- 55. What is true
 - What is true
 - (a) Toadstool is an edible fungus
 - (b) Rust fungi are homoecious
 - (c) Parathecium is fruiting body
 - (d) In mushroom gills produce basidia
- 56. A combined solution of copper sulphate and calcium hydroxide which is used as a fungicide is
 - (a) Fehling solution
- (b) Folins mixture
- (c) Carminative mixture
- (d) Bordeaux mixture
- 57. Parasexuality is involved with
- [RPMT 2006]
- (a) Fusion of gamete and protoplast
- (b) Fusion of male gamete with secondary nucleus
- (c) Fusion of protoplast
- (d) Fusion of male and female gamete
- **58.** The disease which occur at irregular intervals and locations are known as
 - (a) Epiphytotic diseases
- (b) Endemic diseases
- (c) Sporadic disease
- (d) Epidemic diseases
- 59. Reserve food material of fungi is

[BHU 1994, 2000; KCET 1998; MP PMT 2000; CBSE PMT 2000; Odisha JEE 2004, 05]

- (a) Starch
- (b) Protein
- (c) Glucose
- (d) Glycogen
- 60. The disease produced by fungus Ustilago are known as smuts because [CBSE PMT 1994]
 - (a) They parasitise cereals
 - (b) The affected host becomes completely black
 - (c) Their mycelium is black
 - (d) They produced sooty mass of spores
- 61. A type of life cycle in which plasmogamy, karyogamy, haplodization take place but not at specific place in life cycle of an organism is called as [RPMT 2002]
 - (a) Parasexuality
- (b) Heterozygosity
- (c) Homozygosity
- (d) Asexuality
- **62.** Deuteromycetes are known as fungi imperfecti because

[AIIMS 2012; AFMC 2012]

- (a) Their zygote undergoes meroblastic and holoblastic cleavage
- (b) Only asexual stages are known
- (c) They have aseptate mycelium
- (d) They are autotrophic
- 63. Match the different types of spores listed under column I with the names of the organisms given under column II. Choose the answer which gives correct combination of the alphabets of the two columns

	Column I		Column II
	Spores		Organisms
A.	Ascospores	p.	Diatoms
B.	Endospores	q.	Agaricus
C.	Auxospores	r.	Bacteria
D.	Basidiospores	s.	Yeast
		t.	Nephrolepis
			IKC

[KCET 1997]

- (a) A = s, B = r, C = p, D = q
- (b) A = s, B = p, C = r, D = q
- (c) A = s, B = p, C = t, D = q
- (d) A = s, B = t, C = p, D = q

Which of the following is the characteristic feature of

75.

76.

78.

79.

81.

Bakanae disease was due to

(c) Inadequate nutrients

(d) Change in photoperiods

(b) Growth homones released by fungal infection

(a) Fungi toxin

[MHCET 2000]

- ascomycetes (b) Spores (a) Hyphae (d) Ascospores (c) Zoospores [DPMT 2006] Phycomycetes is a class in kingdom 65. (a) Protista (b) Fungi (c) Plantae (d) Animalia [Odisha JEE 2005] Fungal flagellum originates from 66. (b) Kinetosome (a) Dictyosome (d) Oxysomes (c) Glyoxysomes Parasexuality was Ist discovered in [DPMT 2003; BVP 2004] 67. (b) Virus (a) Bacteria (d) None of these (c) Fungi Phytoalexins are secreted by plants in response to fungal 68. reaction. These compounds are generally [DPMT 2003; BVP 2004] (a) Proteins (b) Glycoproteins (c) Phenolic compounds (d) Lipids The chemical produced by the host plant to protect 69. themselves against fungal infection is [MHCET 2002; Pb. PMT 2004] (b) Phytoalexin (a) Toxin (d) Hormone (c) Phytotoxin Clamp connection is found in 70. [Odisha JEE 2004; BHU 2006; MP PMT 2009] (a) Basidiomycetes (b) Ascomycetes (c) Saccharomycetes (d) Haplomycetes [MHCET 2000; Black rust of wheat is caused by 71. BVP 2004; BHU 2008; CBSE PMT (Mains) 2010] (a) Puccinia graminis (b) Ustilago (d) None of these (c) Pythium Which of the following fungi is found useful in the biological [CPMT 2004] control of plant disease (a) Penicillium notatum (b) Phytophthora parasitica (c) Mucor mucido (d) Trichoderma viridae [MHCET 2004] 73. Ergot fungus produces (b) LSD (a) Charas (d) Ganja (c) Marijuana Chloromycetin is obtained from [MHCET 2004] 74. (a) Saccharomyces cerevisiae (b) Streptomyces venezualae (c) Streptomyces griseus (d) Streptomyces erythraeus
- Which of the following correctly represents the type of life [Kerala PMT 2008] cycle patterns from the options given Sporophyte (2n) Gametogenesis Zygote (2n) Meiosis Syngamy Zygote (2n) Meiosis Syngamy Spores (n) Gametogenesis Gametophyte (n) Sporophyte (2n) Zygote (2n) Meiosis Syngamy Spores (n) Gametogenesis Gametophyte (n) 2. Haplodiplontic 3. Haplontic (a) 1. Diplontic 3. Diplontic (b) 1. Haplodiplontic 2. Haplontic 3. Haplodiplontic 2. Diplontic (c) 1. Haplontic 3. Haplodiplontic (d) 1. Diplontic 2. Haplontic 2. Haplodiplontic 3. Diplontic (e) 1. Haplontic Which of the following is an edible 'Fungi' [BHU 2005; CPMT 2009] (b) Penicillium (a) Mucor (d) Rhizopus (c) Agaricus Saprophytic and parasitic modes of nutrition are found in [CPMT 2001, 05] (b) Viruses (a) Bacteria (c) Fungi (d) Both (a) and (c) Claviceps purpurea grows as parasite [CPMT 2005] (b) In sugar cane roots (a) In human gut (d) On fruits of grasses (c) On pine needles In addition to absence of chlorophyll what is the other difference between fungi and higher plants [DPMT 2006] (a) Type of nutrition and composition of cell wall (b) Cell type (c) Nucleus (d) Reproduction Which one of the following fungi contains hallucinogens [CBSE PMT 2014] (b) Ustilago sp. (a) Neurospora sp. (d) Amanita muscaria (c) Morchella esculenta [Wardha 2005]

UNIVERSAL BOOK DEPOT 1960

- 82. The disease root-knot of brinjal is caused by [Kerala PMT 2006]
 - (a) Fusarium udum
- (b) Phytophthora infestans
- (c) Meloidogyne incognita
 - (d) Pseudomonas rubilieneans
- (e) Xanthomonas citri
- 83. Select the false statement

[Kerala PMT 2006]

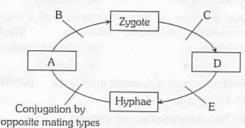

- (a) Scientists who study and contribute to the classification of organisms are known as systematists
- (b) Carolus Linnaeus developed the first scientific system of naming species
- (c) A five Kingdom arrangement of organisms was introduced by R. H. Whittaker
- (d) Genus is a group of species which are related and have less characters in common as compared to species
- (e) Phycomycetes are called club fungi because of a club shaped end of mycelium known as basidium
- 84. Red rot of sugarcane and white rust of radish are respectively caused by

[Odisha JEE 2005, 11; Kerala PMT 2006]

- (a) Albugo candida and Cercospora
- (b) Colletotrichum and Fusarium
- (c) Pythium and Phytophthora
- (d) Albugo candida and Puccinia graminis
- (e) Colletotrichum and Albugo candida
- **85.** Identify from the following examples, a fungus which is of medicinal importance [KCET 2006]
 - (a) Agaricus
- (b) Saccharomyces
- (c) Penicillium
- (d) Cercospora
- 86. Which one of the following is true for fungi

[NEET (Kamataka) 2013]

- (a) They lack a rigid cell wall
- (b) They are heterotrophs
- (c) They lack nuclear membrane
- (d) They are phagotrophs
- 87. The given below figure shows a generalized life cycle of a fungus. The suitable terms for A, B, C, D and E are [NCERT]

	A	В	С	D	E
(a)	Meiosis	Mitosis	Spore	Fertilization	Dikaryotic phase
(b)	Dikaryotic phase	Fertilization	Meiosis	Spore	Mitosis
(c)	Fertilization	Meiosis	Mitosis	Dikaryotic phase	Amitosis
(d)	Mycelium	Mitosis	Meiosis	Fertilization	Spore

88. Which one of the following is wrong for fungi

[NEET (Phase-II) 2016]

- (a) They are both unicellular and multicellular
- (b) They are eukaryotic
- (c) All fungi possess a purely cellulosic cell wall
- (d) They are heterotrophic

Mucor and Rhizopus

- The pathogen Microsporum responsible for ringworm disease in humans belongs to the same Kingdom of organisms as that of [CBSE PMT (Mains) 2011]
 - (a) Rhizopus, a mould
- (b) Ascaris, a round worm
- (c) Taenia, a tapeworm
- (d) Wuchereria, a filarial worm
- Coenogametes are formed in

[CPMT 1999]

(a) Albugo

2.

- (b) Saccharomyces
- (c) Rhizopus
- (d) Alternaria
- **3.** Arrange the following in correct sequence with reference to sexual reproduction in *Rhizopus*
 - (I) Formation of germ tube
 - (II) Formation of zygophores
 - (III) Formation of warty wall layer of zygospore
 - (IV) Secretion of trisporic acid

The correct sequence is

[EAMCET 2009]

- (a) IV, III, II, I
- (b) IV, II, III, I
- (c) II, I, IV, III
- (d) I, III, II, IV
- **4.** Which of the following environmental conditions are essential for optimum growth of *Mucor* on a piece of bread
 - A. Temperature of about 25°C
 - B. Temperature of about 5°C
 - C. Relative humidity of about 5%
 - D. Relative humidity of about 95%
 - E. A shady place
 - F. A brightly illuminated place

Choose the answer from the following options

[CBSE PMT 2006]

- (a) B, D and E only
- (b) B, C and F only
- (c) A, C and E only
- (d) A, D and E only
- 5. In Mucor, asexual reproduction takes place by
 - (a) Motile zoospores
- (b) Spores
- (c) Zoogametes
- (d) Zygospores
- Which one of the following life cycle is associated with Mucor
 - (a) Haplontic
- (b) Diplontic
- (c) Isomorphic
- (d) Heteromorphic
- 7. Zygospores are formed in

[MP PMT 1995; AFMC 2002; Odisha JEE 2005]

- (a) Puccinia
- (b) Penicillium
- (c) Alternaria
- (d) Mucor / Rhizopus
- Which one is wrong statement
- [AIPMT 2015]
- (a) Mucor has biflagellate zoospores
 - (b) Haploid endosperm is typical feature of gymnosperms
 - (c) Brown algae have chlorophyll a and c and fucoxanthin
 - (d) Archegonia are found in bryophyta, pteridophyta and
- gymnosperms

 9. Columella is a specialized structure found in the sporangium of [CBSE PMT 1999; BHU 1999;
 - (a) Ulothrix
- (b) Rhizopus
- (c) Spirogyra
- (d) None of these

CPMT 2004; Bihar CECE 2006]

2005			
10.	Which of the following induces sexual reproduction in Mucor/ Rhizopus	22.	Yeast like budding of oidia in Mucor/ Rhizopus is called [MP PMT 2001]
	(a) Indole acetic acid (b) Trisporic acid		
	(c) Gibberellic acid (d) Citric acid		
11.	In Rhizopus, hyphae are [RPMT 2002]	23.	
	(a) Branched, septate and uninucleate	23.	
	(b) Branched, aseptate and multinucleate		
	(c) Unbranched, aseptate and multinucleate	24.	(c) Saprophytic (d) Autotrophic
	(d) Unbranched, septate and coenocytic	24.	Mycelium of Mucor/ Rhizopus is [MP PMT 2000] (a) Aseptate and unicellular (b) Septate and unicellular
12.	Multinucleated filament of Rhizopus is		(c) Septate and multicellular (d) Coenocytic
	[RPMT 1997; BCECE 2005]	25.	Food stored in Rhizopus / Mucor as
	(a) Coenocytic (b) Conidia	23.	
	(c) Heterothallus (d) Homothallus		[CBSE PMT 1992; RPMT 1996, 2000]
13.	Mucor shows [MP PMT 2002]		(a) Protein and steriods(b) Sugar and oil(c) Protein and starch(d) Glycogen and oil
	(a) Isogamy (b) Anisogamy	96	
	(c) Oogamy (d) None of the above	26.	The wall of Rhizopus hypha is composed of
14.	Sporangiospores of <i>Mucor</i> are [MP PMT 2002]		[MP PMT 2001; PET (Pharmacy) 2013]
	(a) Haploid (b) Diploid		(a) Cellulose (b) Chitin (c) Pectin (d) Hemicellulose
	(c) Triploid (d) Polyploid	NAME OF TAXABLE PARTY.	
15.	For Mucor zygospore is [DPMT 2007]		Yeast and Albugo
	(a) Thick walled resting spore	1.	Botanical name of species which cause white rust of
	(b) Haploid in structure		cruciferae [RPMT 2002,06]
	(c) Result of asexual reproduction		(a) Peronospora parasitica (b) Puccinia graminis (c) Pythium debaryanum (d) Albugo candida
	(d) Germinates to form zoospores	2.	Fungus without any mycelium is
16.	The zygospore in Rhizopus develops into	2.	[BHU 2000; MHCET 2000]
	[J & K CET 2002]		(a) Albugo (b) Agaricus
	(a) Zygospore (b) Promycelium		(c) Puccinia (d) Saccharomyces
	(c) Progametangium (d) Gametangium	3.	Branched, aseptate, coenocytic mycelium present in
17.	The reduction division in the life cycle of Rhizopus occurs	-	[RPMT 2002]
	(a) At the time of germination of zygospores		(a) Aspergillus (b) Albugo
	(b) During the formation of germ sporangium		(c) Penicillium (d) Erysiphae
	(c) During asexual reproduction	4.	Yeast produces an enzyme complex that is responsible for
	(d) During the formation of gametangium		fermentation. The enzyme complex is [MP PMT 2013]
18.	Which of the following plant and its mode of nutrition is not		(a) Aldolase (b) Dehydrogenase
	correctly matched [AIEEE Pharmacy 2003]		(c) Invertase (d) Zymase
	(a) Cuscuta – Stem parasite	5.	
	(b) Mucor – Autotroph		(a) Biflagellated male gametes
	(c) Orobanche – Root parasite		(b) Non-flagellated female gametes
	(d) Drosera - Insectivorous		(c) Biflagellated zoospores
19.	Which one of the following fungus shows heterothallism		(d) All of the above
	[BHU 1999; MHCET 2001]	6.	Which of the following is an unicellular sac-fungus
	(a) Erisyphe (b) Peziza		[Kerala PMT 2011] (a) Claviceps (b) Saccharomyces
	(c) Rhizopus (d) Peronospora		(a) Claviceps (b) Saccharomyces (c) Penicillium (d) Neurospora
20.	Common bread mould is [MP PMT 1996, 2010, 12;		(e) Aspergillus
	CBSE PMT 2001]	7.	Yeast is not included in protozoans but in fungi because
	(a) Rhizopus oryzae (b) Rhizobium species		[Manipal 2005]
	(c) Rhizopus nedosus (d) Rhizopus stolonifer		(a) It has no chlorophyll
21.	In Rhizopus if conjugation fails, gametangia behave as zygospore. It is called as [AIIMS 2000]		(b) Some fungal hyphae grow in such a way that they give the appearance of pseudomycelium
	(a) Conidia (b) Parthenospore		(c) It has eukaryotic organisation
	(c) Gametangia (d) Sporangiospore		(d) Cell wall is made up of cellulose and reserve food

Fungi (Multicellular decomposers) 95 BOOK DEPOT 19 8. Mycelium in Albugo is [RPMT 1995] 6. Mycorrhiza works as [CPMT 1998; BHU 2002] (a) Intracellular (b) Intercellular (a) Modified root (c) Surface of host (d) Surface of flower (b) An organism for vegetative propagation In Albugo the food reserve is mostly [RPMT 1995] (c) A root hair in adverse condition (a) Glycogen (b) Volutin granules (d) Mechanical tissue for support (c) Protein granules (d) Fat 7. Which statements is wrong about lichens [CBSE PMT 1996] 10. Yeast is divided under the class [CPMT 2003] (a) Some species are eaten by reindeers (a) Basidiomycetes (b) Deuteromycetes (b) Lichens are indicators of pollution (c) Ascomycetes (d) Zygomycetes Which organism is used to obtain the single cell protein 11. (c) They grow rapidly about 2cm per day (d) They have symbiotic relationship between alga and [AMU (Med.) 2005] (a) Bacteria (b) Yeast fungus (c) Filamentous Fungi (d) All of the above 8. Fungal partner of a lichen is commonly [BHU 1996] In manufacture of bread, it becomes porous due to release (a) Ascomycetes (b) Basidiomycetes of CO2 by the action of [CBSE PMT 2002] (c) Phycomycetes (d) Deuteromycetes (a) Virus (b) Yeast 9. Mycorrhizal association occurs in Pinus, Ficus and (c) Bacteria (d) Protozoans Pseudomycelium is formed in [HPMT 2000] [BHU 2002] (a) Utricularia (a) Yeast (b) Legumes (b) Rhizophora (c) Eucalyptus (d) Azardirachta (c) Aspergillus (d) Synchytrium Fungus/Lichens which grow on wood is 10. Lichen and Mycorrhiza (a) Terricolous (b) Saxicolous 1. 'Mycorrhizae' are useful for plants mainly due to their (c) Lignocolous (d) Corticolous following attribute [CPMT 1993, 94, 2004; Short twisted strands of hyphae which serves as anchors for 11. BHU 1994, 2001; Pb. PMT 1999; DPMT 2003, 06; [Odisha JEE 2008] **RPMT 20061** (a) Mycelium (b) Rhizines (a) Fixing atmospheric nitrogen (c) Roots (d) Rhizoids (b) Enhanced absorption of nutrients from soil A teacher was explaining about a constant physical contact (c) Killing insects and pathogens involving almost equal physiological interdependence in two different thaloid forms. He was trying to explain one of the (d) Providing resistance against abiotic stresses following [EAMCET 2009] In lichens, sexual reproduction belongs to 2. [BHU 1994] (a) Mycorrhizal association (a) Fungal partner only (b) Establishment of heterothallism (b) Algal partner only (c) Operation of heterothallism (c) Fungal and algal partners (both) (d) Advent of lichen formation (d) Either fungal partner or algal partner (not both) In majority of lichens, there is association of [CBSE PMT 2001] 13. 3. Which one of the following pairs is correctly matched (a) Green algae and ascomycetes [AIIMS 2003, 07] (b) Green algae and basidiomycetes (a) Rhizobium Parasite in the roots of (c) Blue green algae and ascomycetes leguminous plants (d) Blue green algae and basidiomycetes (b) Mucorrhizae 14. Lichen is Mineral uptake from soil [BHU 2008] (a) Saprophytic (c) Yeast (b) Parasitic Production of biogas (c) Holozoic (d) Autotrophic (d) Myxomycetes The disease ring worm Lichens grow at a very slow rate (1 mm per year). In how 4 Mycorrhiza is a [CPMT 1994] many years a lichen matures (a) Long thin root (a) 1 - 4 years (b) 4 - 8 years (b) Association of root and fungus (c) 100 years (d) 20 - 25 years (c) Root like underground stem There exists a close association between the algae and the (d) Parasitic root fungus within a lichen. The fungus [CBSE PMT 2005] The symbiotic association of fungi and algae is called (a) Fixes the atmospheric nitrogen for the alga [CPMT 1996, 98; AFMC 1998; KCET 2000; (b) Provides protection, anchorage and absorption for the Chd. CET 2000; CBSE PMT 2001; J & K CET 2012] alga (a) Lichen (b) Mycorrhiza (c) Provides food for the alga (c) Both (a) and (b) (d) Mycoplasma (d) Releases oxygen for the alga

17.	An example of endomycorrhiza is[CBSE PMT (Mains) 2010]	-	
	(a) Nostoc (b) Glomus		NCERT
	(c) Agaricus (d) Rhizobium	-	
18.	Lichens are ecologically important as they	-	Exemplar Questions
	(a) Purify air	1.	Naked cytoplasm, multinucleated and saprophytic are the
	(b) Are pioneers of barren rocks		characteristics of [NCERT]
	(c) Are symbionts of algae and fungi		(a) Monera (b) Protista
	(d) Are associated with mycorrhizal roots		(c) Fungi (d) Slime molds
19.	Reindeer moss is [AFMC 1996; RPMT 1999]	2.	An association between roots of higher plants and fungi is
	(a) Sphagnum (b) Marchantia	2.	
	(c) Cladonia rangiferina (d) None of these		called [NCERT]
20.	Association of fungus with roots of tracheophytes is		(a) Lichen (b) Fern
	[BVP 2002]		(c) Mycorrhiza (d) BGA
	(a) Mycorrhiza (b) Commensalism		A dikaryon is formed when [NCERT]
	(c) Helotism (d) Amensalism		(a) Meiosis is arrested
21.	Which one of the following helps in absorption of phosphorus from soil by plants [CBSE PMT (Pre.) 2011]		(b) The two haploid cells do not fuse immediately
			(c) Cytoplasm does not fuse
	Or Or		(d) None of the above
	Which one of the following microbes forms symbiotic	4.	Mycobiont and Phycobiont are found in [NCERT]
	association with plants and helps them in their nutrition [CBSE PMT (Pre.) 2012]		(a) Mycorrhiza (b) Root
			(c) Lichens (d) BGA
	(a) Azotobacter (b) Glomus	5.	With respect to fungal sexual cycle, choose the correct
	(c) Aspergillus (d) Trichoderma		sequence of events [NCERT]
22.	Mycorrhiza is a relationship of roots of Pinus and		(a) Karyogamy, Plasmogamy and Meiosis
	[BVP 2001; MHCET 2001]		(b) Meiosis, Plasmogamy and Karyogamy
	(a) Fungus (b) Alga		
	(c) Bacteria (d) Ants		
23.	Which of the following symbiotic association is not useful as		(d) Meiosis, Karyogamy and Plasmogamy
	biofertilizer [MHCET 2002]	6.	Members of phycomycetes are found in
	(a) Rhizobium and leguminous roots		i. Aquatic habitats
	(b) Algae and fungi		ii. On decaying wood
	(c) Azolla and Anabaena		iii. Moist and damp places
	(d) Roots of higher plants and fungi		iv. As obligate parasites on plants
24.	Mycorrhiza exhibits the phenomenon of		Choose from the following options [NCERT]
	[CBSE PMT 1994; BVP 2002]		(a) None of the above (b) i and iv
	(a) Antagonism (b) Endemism		(c) ii and iii (d) All of the above
25.	(c) Parasitism (d) Symbiosis Helotism is a term used for the symbiosis of [MHCET 2003]	-	
23.	(a) Algae and bacteria (b) Algae and bryophytes	-	Critical Thinking
	(c) Algae and pteridophytes (d) Algae and fungi		
26.	Litmus is obtained from [Odisha JEE 2004]		Objective Questions
	(a) Lichen (b) Algae	1	
	(c) Fungi (d) Protozoa	1.	Which of the following is not matched correctly [Kerala PMT 2011]
27.	Lichens are well known combination of an alga and a		[Relaia FMT 2011]

(a)	Anabaena	-	Cyanobacteria
(b)	Amoeba	-	Protozoa
(c)	Gonyaulax	-	Dinoflagellates
(d)	Thermoacidophils	-	Archaebacteria
(e)	Albugo	-	Chrysophytes

'Torula condition' occurs in

(a) Rhizopus

(b) Ulothrix

(c) Spirogyra

(d) Riccia

28. Cladonia rangiferina is a/an (a) Algae

(b) Lichen

[CBSE PMT 2004; Pb. PMT 2004; CPMT 2005]

(c) Fungus

fungus where fungus has

(a) A parasitic relationship with the alga (b) A symbiotic relationship with the alga (c) A saprophytic relationship with the alga (d) An epiphytic relationship with the alga

(d) Angiosperm

[BHU 2004]

Match the following and choose the correct combination from the ontions giv

110	in the options given		
	Column I		Column II
	(Group)		(Example)
A.	Eubacteria	1.	Trichoderma
B.	Dinoflagellates	2.	Albugo
C.	Phycomycetes	3.	Gonyaulax
D.	Deuteromycetes	4.	Anabaena
	[J 8	KCE	T 2012; Kerala PMT 20
(a)	A-1; B-2; C-3; D-4	(b)	A-2; B-3; C-4; D-1

012]

	(c) A-4; B-3; C-2; D-1	(d)	A-3; B-4; C-1; D-2
	(e) A-4; B-3; C-1; D-2		
4.	A fungus which requires only of its life cycle is called	one	single host for completion [Chd. CET 2000]
	(a) Heteroecious	(b)	Autoecious
	(c) Heterothallism	(d)	Heterosporous

5. Fungi can be stained by [AFMC 1993; BVP 2000] (a) Safranine (b) Iodine

(c) Lactophenol (d) Cotton blue

6. Asci are formed in (a) Ascobolus (b) Saccharomyces (c) Penicillium (d) All the above

No need of water for fertilization in 7. [RPMT 1995] (a) Ulothrix (b) Albugo (c) Bryophyta (d) Pteridophyta 8. Ray fungi are [BHU 1995]

(a) Ascomycetes (b) Basidiomycetes (c) Actinomycetes (d) Phycomycetes

9 Which one of the following group of fungi is sometimes known as "fungal waste basket"

(a) Phycomycetes (b) Ascomycetes (c) Basidiomycetes (d) Deuteromycetes 10. In Puccinia, infection from barberry leaf to wheat plant is caused by [JIPMER 2001] (a) Pycnospores (b) Aecidiospores

(c) Uredospores (d) Teleutospores 11. Powdery mildews of crops are caused by

(a) Bacteria (b) Ascomycetes (Erysiphe) (c) Phycomycetes (d) Basidiomycets 12. Which of the following fungal disease spreads by seed and

flowers [CBSE PMT 2002] (a) Corn stunt (b) Covered smut (c) Potato root (d) Loose smut of wheat

13. The edible part of mushroom is

[CPMT 2003; BHU 2006; WB JEE 2011]

[AIIMS 2001; MHCET 2003; Odisha JEE 2012]

(a) Basidiopcarp (b) Tertiary mycelium (c) Primary mycelium (d) Secondary mycelium

14. Which one single organism or the pair of organisms is correctly assigned to its or their named taxonomic group

[CBSE PMT (Pre.) 2012]

(a) Paramecium and Plasmodium belong to the same kingdom as that of Penicillium

(b) Lichen is a composite organism formed from the symbiotic association of an algae and a protozoan

(c) Yeast used in making bread and beer is a fungus

(d) Nostoc and Anabaena are examples of protista

Which option shows incorrectly matched group

[GUJCET 2014]

(a) Pseudopodiospore - Plasmodium - Sporulation

(b) Gemmules - Spongilla - Budding

(c) Zoospores - Aspergillus - Sporulation

(d) Conidia - Penicillium - Asexual reproduction

16. Catabolism Considering mode of asexual reproduction, match the Column I with II and select the correct option

1-	I	4	II
A.	Yeast	1.	Fragmentation
B.	Penicillium	II.	Zoospores
C.	Filamentous algae	III.	Budding
D.	Chlamydomonas	IV.	Conidia

[MHCET 2015]

(a) A-III, B-IV, C-I, D-II (b) A-II, B-III, C-I, D-IV (c) A-IV, B-III, C-II, D-I (d) A-III, B-II, C-I, D-IV

Read the assertion and reason carefully to mark the correct option out of the options given below:

If both the assertion and the reason are true and the reason (a) is a correct explanation of the assertion

(b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion

(c) If the assertion is true but the reason is false (d)

If both the assertion and reason are false If the assertion is false but reason is true (e)

1. Assertion Symbiosis is furnished by mycorrhiza.

In mycorrhiza, symbiosis is established Reason between fungus and alga. [AIIMS 1995]

2 Assertion Fruticose are well branched leafy lichens. Reason These lichens are upright and have pendulous organisation and are attached to substratum by a discoid structure.

[AIIMS 1996]

3. Assertion Aflatoxins are produced by Aspergillus flavus. Reason These toxins are useful to mankind.

[AIIMS 2000, 13]

4. Assertion Deuteromycetes lack sexual reproduction. Reason

Fungi show three type of reproduction asexual, sexual and vegetative. 5. Assertion "Fungi imperfecti" does not show

alternation of generation. Reason The diploid phase is present in only zygote.

6. Assertion Rhizopus and Mucor are used in liquor industry.

Reason They cause fermentation.

7. Assertion Morels and Truffles are edible fungi. Reason Ascocarps are edible.

8. Assertion Saccharomyces ellipsoidens is Baker's yeast and Saccharomyces cerevisiae is Wine yeast.

Reason Yeast is used to make dry ice.

9. Assertion : Yeast are the best source of vitamin B

complex.

Reason : Ashbya gossypii is a filamentous yeast.

10. Assertion : Claviceps produces lysergic acid.

Reason: It is carcinogenic.

11. Assertion : Mushrooms are called fairy rings.

Reason : Mushroom consists of two parts-stipe and

pileus.

12. Assertion : Basidiocarps are called fungus flowers.

Reason : The beautiful fruit bodies are found in

Basidiomycotina.

13. Assertion : Fruticose lichens have the simplest thallus.

Reason : The thallus is attached only at the base by

a flattened disc.

14. Assertion : The fungi are widespread in distribution

and they even live on inside other plants

and animals.

Reason : Fungi are able to grow anywhere on land,

water or on other organisms because they have a variety of pigments, including chlorophyll, carotenoids, fucoxanthin and

phycoerythrin. [AIIMS 2005]

1.

Fungi (General)

- (a) The term fungus was used by Gaspard Bauhin (1560-1624).
- (c) Father of modern mycology and plant pathology is H.A. De Bary (a German botanist).

- (b) Due to the presence of mentioned characters in question, this group is also called fungi imperfecti.
- (c) Conidia are non-motile spores produced exogenously by constrictions at the tip of special hyphae called conidiophores.
- 11. (a) Heterotrophs: Fungi (lack chlorophyll) obtain their nutrition from the extracellular digestion and absorption of the digested material such mode of nutrition is called heterotrophic and the organism celled heterotrophs.
- (d) T.S. Sadasivan work on physiology of infection by Fusarium. Other famous Indian mycologists are K.C. Mehta, B.B. Mundkar and C.V. Subramaniyam.
- (c) Koch postulates are applicable to bacteria and fungi as pathogen.
- (d) Brown leaf spot of rice is a seed born disease, which is caused by Helminthosporium oryzae.
- (b) Morel and truffles are edible and members of Ascomycetes in fungi.
- (a) Mushroom is a basidiomycetes fungus, which is grow on dead and decay matter.
- 24. (c) Covered smut of barley is caused by Ustilago hordei.
- 25. (b) Late blight of potato is a seed born disease which is caused by *Phytophthora infestans*. The disease is characterised by brownish to blackish dead areas on the tip and margin of the leaflet leading to blighting of the whole leaf. So the tuber formation is reduced.
- 27. (c) All fungi are heterotrophs in their nutrition. Some are depends upon organic matter known as saprophytes.
- 28. (b) Modes of nutrition is three types:(a) Saprophytic (b) Parasitic (c) Symbiotic (Mycorrhiza).
- 29. (d) The members of division basidiomycota (class basidiomycetes) are commonly called club fungi because the basidia are club shaped.
- 30. (c) Aflatoxins are produced by fungi (Aspergillus flavus).
- 32. (c) The septum of higher fungi is more complex dolipore (Latin dolium = a large jar). It is a barrel shaped pore with open end.
- 33. (c) Aspergillus flavus grows on stored cereal grains, groundnut and areca nut produce a carcinogenic toxin called aflatoxin.
- **35.** (b) The mycelium of Aspergillus consist of branch septate hyphae. Cells of hyphae are multinucleate.
- 37. (a) In gametangial copulation two gametangia come in contact and fuse completely to form a zygote or zygospore. It is found in members of zygomycetes, e.g., Rhizopus and Mucor.

- 39. (b) It is the first stage of sexual reproduction in which the cytoplasm of two sex cells fuse with each other. The nuclei of sex cells come close to each other but do not fuse. Thus the resulting cell becomes binucleate or dikaryon.
- 43. (c) Many scientist (Sachs, 1874; Bessey, 1950) believe that fungi, particularly class Phycomycetes, have evolved from siphonaceous green algae. Both the group have some common features such as presence of coenocytic thalli, flagellated zoospores, streaming movement and mode of sexual reproduction. Therefore Phycomycetes is called algal fungi.
- 44. (b) The fungus Aspergillus produces aflatoxins which are carcinogenic and may cause cancer in human beings.
- 49. (c) Many species of Neurospora have been used as convenient organisms for genetical (one gene – one enzyme theory by Beadle and Tatum) and biochemical studies. Neurospora is also known as Drosophila of plant kingdom.
- **52.** (b) Coprophillous fungi grow on dung. e.g., Pilobolus crystallinus.
- 56. (d) Bordeaux mixture was the first fungicide to be discovered. It is discovered by proff. Millardet of Bordeaux university. This mixture consists of copper sulphate, lime and water (calcium hydroxide). This mixture is called holy water of plant pathology and effective against white rust, mildews and blights.
- (c) Parasexuality is related with protoplast fusion and found in fungus.
- **58.** (c) Sporadic disease occurs occasionally at irregular intervals in fewer area and only few plants in a locality are infected, e.g., Blotch disease of cucumbers, angular leaf spot of cotton.
- 64. (d) In ascomycetes, diploid nucleus divided by meiosis and then by mitosis to form 8 (sometimes only 4) haploid ascospores. These sexually produced ascospores remain inside the sac like structure called ascus.
- 67. (c) Parasexuality was first discovered by Pontencorvo and Roper (1952) in a fungus Aspergillus nidulans. Parasexuality help in recombination without meiosis and fertilization.
- **68.** (c) Phytoalexins are phenolic compound produce in the host cell for defense in response to fungal infection (Muller and Borger, 1940). These chemicals inhibit growth of the parasite.
- 70. (a) In many members of basidiomycetes cells division accompained by clamp connection. These are bridge (hook) like connection. They function as bypass hyphae through which nuclei migrate to make all of mycelium dikaryotic.
- 71. (a) Puccinia graminis tritici causes black rust of wheat.
- 73. (b) LSD (Lysergic acid diethylamide) is the most powerful hellucinogen. It is a crystaline amidated alkaloid obtained from ergot. i.e., an extract got from a fungus Claviceps purpurea, that is parasite on rye.

- (b) Chloromycetin is an antibiotic which obtained from Streptomyces venezualae.
- 76. (c) The fructifications of certain fungi are used as nutritous and delicious food e.g., Agaricus bisporus and A. campestris (mushrooms).
- 77. (d) Both are heterotrophic in their mode of nutrition, so they are saprophytic or parasitic.
- 78. (d) Claviceps purpurea (ergot fungus) causes ergot of cereals especially of rye (secale cereale).
- 79. (a) Fungi lack chlorophyll, therefore, heterotrophic in nature. Their cell wall is formed of chitin (fungus cellulose). The cells in higher plants and fungi is eukaryotic i.e., possess a well developed nucleus.
- 80. (d) Amanita muscaria is noted for its hallucinogenic properties, with its main psychoactive constituent being the compound muscimol.
- 81. (b) Bakane disease of rice is caused by Fusarium moniliforme. The perfect stage of this fungus is Gibberella fujikuroi (ascomycete). Gibberella produces the plant hormone gibberellin.
- 88. (c) Cell wall of fungi is made up of chitin and polysaccharides.

Mucor and Rhizopus

- (c) Each progametangium of Rhizopus undergoes division to form gametangium and suspensor. The two gametangia are in contact with each other. They contain multinucleate protoplasts that behave as aplanogamete or coenogamete.
- (b) In asexual reproduction of Mucor three type of nonmotile mitospores are produced. i.e., sporangiospores, chlamydospores and oidia.
- (d) Fusion of coenogametes (Rhizopus and Mucor) produced a diploid resting spore called zygospore.
- 9. (b) The sporangium of Rhizopus is appear to be divide into two regions, i.e., Outer fertile sporiferous zone and a central sterile columella. The protoplast of the sporiferous zone cleave mitotically to form dark coloured multinucleate spores.
- 10. (b) The process is initiated by the secretion of trisporic acid which stimulates the formation of special hyphae, called zygophores, from both of the compatible mycelia (+) strain and (-) strain.
- **12.** (a) The hyphae are aseptate and multinucleate (i.e., Coenocytic).
- (a) Both (+) and (-) progametangium are similar in structure.

- 14. (a) Sporangiospores are produced in large number inside the sporangia of *Mucor*, which are borne over special hyphae known as sporangiophore. These spore are produced during asexual reproduction.
- 16. (b) Sexual reproduction results in the formation of diploid zygospore. The zygospore absorbs water and swell. The exospore ruptures and the endospore protrudes out in the form of a hypha, called promycelium.
- (c) When in Rhizopus (+) and (-) strains are found separately (physiologically), then this condition is called as heterothallism.
- (d) Rhizopus (pin mould or black mould) grows on bread and hence also called bread mould.
- **22.** (c) In liquid medium, rich in sugar and acidic *pH*, the hyphae of *Rhizopus/Mucor* produce small rounded oidia, which multiply by budding like yeast. This budding condition is called torula stage.

Yeast and Albugo

- (d) The yeast cells secrete extracellular enzyme-zymase which converts complex sugar into simple soluble sugar.
- 8. (b) The mycelium is intercellular branched, aseptate and multinucleate. The mycelium produces finger like or globular haustoria which enter into the host cells to absorb the food material.
- 10. (c) True yeast bear asci which are not organized into ascocarps. e.g., Schizosaccharomyces, Saccharomyces, Saccharomycodes, , Zygosaccharomyces, Nematospora. Therefore, yeast are classified under ascomycetes.
- 12. (b) Selected strains of Saccharomyces are used as Baker's yeast. It is available as powder or cake. The same is added to flour during kneading. Yeast secretes amylase (change some starch to maltose), maltase (maltose to glucose) and zymase (glucose to ethyl alcohol and CO₂). The dough swells up or leavens. Leavened dough is baked. Both alcohol and CO₂ evaporate. The bread becomes soft and porous.
- 13. (a) Yeast reproduces by means of budding. Sometime the bud starts forming new bud before it separates from parent cell. This may result in formation of branched and unbranched chains of bud which is called as pseudomycelium.

Lichen and Mycorrhiza

- (a) Sexual reproduction in lichen is performed only or mainly by its fungal component.
- (c) In adverse conditions ectomycorrhiza work as root hairs
 to absorb water as in *Pinus*. Because gymnosperms do
 not have root hair.
- (c) Lichen are slow growing and grow at the rate of 1 mm per year.

- (c) In lichens fungus partner or mycobiont (mostly ascomycete) and an algal partner called photobiont or phycobiont (mostly blue-green alga).
- (b) Nostoc BGA, Agaricus-Basidiomycetes, Rhizobium-Eubacteria
- (b) Lichens are considered as pioneers in initiating a plant succession on rocks.
- **19.** (c) Reindeer moss (*Cladonia rangiferina*) of the arctic region is the used as food for reindeer and cattle.
- (b) Glomus is a endomycorrhiza for phosphorus absorption.
- 24. (d) Mycorrhiza is a symbiotic association of a saprophytic fungus with the roots of higher.
- **25.** (d) Helotism is a form of symbiosis in which one partner benefits more than the other. *e.g.*, Fungus in lichen thallus benefits more than the alga.
- (a) Litmus used as acid-base indicator is obtained from Roccela montagnei and Lasollia pastulata.

Critical Thinking Questions

- (d) Fungi can be stained with cotton blue. This stain provide blue colour of chitinous cell wall.
- (d) Ascobolus, Saccharomyces and Penicillium belong to ascomycetes.
- (b) In algae (*Ulothrix*), bryophytes and pteridophytes, water is necessary for fertilization.
- (d) Duteromycetes is also known as fungal waste basket because its lack perfect sexual stage.
- 11. (b) Powdery mildew diseases are characterized by the presence of fungal mycelium, conidiophore and conidia as white powdery patches on the host. Powdery mildew is caused by fungi which belongs to ascomycetes.
- (d) Loose smut of wheat is caused by Ustilago tritici, which is seed borne disease.
- (a) Basidiocarp is a fruiting body of basidiomycetes. It is a edible part of mushroom.
- (c) Saccharomyces cerviciae is a yeast used in making bread (Baker's yeast) and commercial production of ethanol.
- 15. (c) Aspergillus do not produce motile spore (zoospore).

Assertion and Reason

- (c) Mycorrhiza represents mutualistic symbiosis between fungus and roots of higher plants. Fungus helps in absorption of minerals and water. Fungus also gets food from plant.
- 2. (e) Fruticose are well branched shruby lichens with upright and pendulous organization. These are attached to substratum by a discoid structure. Plant body can be divided into prostrate, leafy and lobed thallus.
- 3. (c) Aflatoxins, are produced by Aspergillus flavus.

 Contaminated food is the main source of infection. This toxin causes aflatoxicosis which may lead to haemorrhage and disease of liver.

- (b) Sexual reproduction is absent (as the sexual stage is absent) in the artificial group of fungi called fungi imperfecti or deuteromycetes.
- 5. (c) Fungi imperfecti is that group of fungi where only the imperfect stage (asexual stages) is present. The only known method of reproduction is by conidia (asexual reproduction). As sexual reproduction is absent in this group therefore diplophase is also absent.
- 6. (a) Both Rhizopus and Mucor species are used in alcoholic fermentation. The two produce a number of organic acids like citric acid, lactic acid and fumaric acid.
- (a) The fructifications of some ascomycetes, i.e., ascocarps are edible, e.g., morels, truffles.
- 8. (b) The two common yeasts used by brewing industry are Saccharomyces cerevisiae (Beer or Baker's yeast) and S. ellipsoidens (Wine Yeast). In the baking or brewing industry CO₂ is the useful product. It is collected, solidified and sold as "dry ice".
- (b) The yeasts are the best sources of vitamin B complex. Riboflavin (B₆) is obtained from a filamentous yeast Ashby gossypii.
- (c) A derivative of ergot known by name of lysergic acid (LSD) is used in experimental psychiatry, as it is a hallucinogen.
- 11. (b) The basidiocarps or mushrooms often lie in rings. Therefore, are spoken as fairy rings. Each basidiocarp consists of two parts-stipe and pileus. The stipe or stalk is fleshy. Pileus is umbrella-like cap of the mushroom.
- 12. (a) The fruit bodies of Basidiomycotina, called basidiocarps are most attractive and beautiful of all fungi and therefore are called fungus flowers.
- 13. (e) Fruticose lichens have a most complex thallus which is slender and freely branched. The branches may be cylindrical or ribbon-like and form thread-like or twiglike tufts. The thallus is attached only at the base by a flattened disc.
- 14. (c) Fungi are considered ubiquitous i.e., they occur in a variety of habitats. Most of them are moisture loving and terrestrial and few (e.g., Monoblepharis) are aquatic. Fungi may be epiphytic (i.e., live on plants e.g., Armillaria), saprophytic (i.e., grow in dead organic matter e.g., Mucor), symbiotic (i.e., live with association with other plants e.g., lichen, mycorrhiza) and predacious (e.g., Dactyldela) and parasitic (e.g., Erysipi) fungi are non-chlorophyllus i.e., devoid of chlorophyll hence cannot prepare their own food. They are heterotrophic and show absorptive type of nutrition.

- Each ascus has 4 to 8 endogenously produced meiospores called ascospores arranged either in linear order (Neurospora) or unorderly (Yeast).
- 2. Penicillium and Aspergillus have cleistothecium fruiting
- (b) Mature gill composed of a central core called trema 3. which is made up of parallel or loosely interwoven
- 4. (a) Keratophilous fungi appear on nails, feathers, hairs etc.
- In Rhizopus, zygospore formation is induced by the 8. hormones trisporic acid B and C.
- 11. (d) Collumella: It is the structure made up of sterile cells e.g., Mucor/Rhizopus and in moss.
- (a) Bird's nest fungi Cyathus, Puffballs Lycoperdon 15. clavatia.
- 18. (c) In class ascomycetes meiosis occurs in ascus mother cell but in yeasts meiosis occurs in zygote and there is no ascus mother cell. Zygote function directly as naked ascus produces ascospores arranged in unorder manner.
- 20. (b) Yeast from brewing industry is harvested and used as a food. It is rich in protein and vitamin-B (Riboflavin).
- In Albugo diploid nucleus undergoes meiosis, followed 21. by several mitotic division. After a period of rest, the oospore germinates and produced reniform, biflagellate zoospores.
- 22. (d) Each soredia form a new thallus under favorable condition
- In hot season, Usnea get dry and become highly 24. inflammable. It easily catches fire and causes
- 25. (c) In some yeast e.g., Zygosaccharomyces chevalieri, the mother and daughter cells fuse to form the zygote and this phenomenon is called pedogamy.
- 29. (d) Yeast are facultative aerobes i.e., they are anaerobes but also survive under aerobic conditions and respire aerobically as well.
- 30. (c) Puccinia rust fungi.

Viruses

The term 'virus' has been derived from Latin, which means poison or venom or viscous fluid. They remain inactive outside a living host but become active inside the host and multiply in it. They represent a transitional form of life between non-living and living world.

Luria (1953) defined virus as "Sub-microscopic entities capable of being introduced into specific living cells and reproducing inside such cells only. "Single virus is called 'Virion', most of the plant virus are RNA virus. Most of the animal virus are DNA virus.

(i) Important discovery of virus

Carolous causius (1576) recorded first viral disease in tulips.

- A. Mayer (1886) found a disease in tobacco caused by virus and called it tobacco mosaic disease.
- D. Ivanowski (1892), a Russian Botanist, discovered the infectious nature of the viruses. He was the person, who discovered the virus.

Beijerinck (1898) Beijerinck called them living infectious fluid or "Cotagium virum fluidum."

- W. Twort (1915) and D. Herelle (1917) discovered bacteriophages, a kind of virus which infected bacteria and destroyed them.
- **W. M. Stanley (1935)** first time isolated tobacco mosaic virus (TMV) in crystalline form and showed that crystals were made up of proteins. Nobel prize was awarded to him for this work.
- (ii) **Nature of viruses**: Viruses are regarded as intermediate between non-living entities and living organisms. It is very difficult to as certain whether they are living or non-living. Some characters of viruses suggest their non-living nature where as many other characters suggest their living nature. The two views are listed below –

Viruses are non-living : The following characters state that they are non-living.

- (a) Viruses have no complete cellular structure. They are not surrounded by cell membrane or cell wall.
 - (b) They do not show cellular metabolism and lack respiration.
 - (c) They possess high specific gravity unlike living organisms.
- (d) Viruses are active only when they are inside the living host cells. Out side the host, they are good as chemical substances. Thus, they do not have their independent existence.
- (e) Postulates of Robert Koch are not true for the viruses. Virus cannot grow in "invitro" condition in lab.
 - (f) Absence of growth and division.

Viruses are living organisms : The following characters state that they are living organisms –

- (a) They have definite shape and morphology like that of a living organism.
- (b) They possess genetic material (DNA or RNA), which determine their structure and development. Genetic material passes from generation to generation in usual manner.
- (c) All viruses are intracellular obligate parasite and attack specific hosts. The bacteriophages recognise the real bacterial surface.
 - (d) They show property of mutation.
- (e) They show irritability and respond to environmental conditions such as heat, ultraviolet rays, humidity, drought, alcohol, etc.
- (f) They can grow inside the host and multiply enormously showing one of the most important property of living organisms.
- (iii) **Chemical composition :** Chemically viruses are nucleoproteins. They are made up of central core of nucleic acid. Nucleic acid is only one, either DNA or RNA. This nucleic acid

UNIVERSAL BOOK DEPOT 1960

(DNA or RNA) represents the genetic characters of virus. TMV has RNA (like most plant viruses have) 10% RNA and 90% protein is present in influenza virus and PSTV (Potato Spindle Tuber Viroid) also has RNA but it does not have capsid (protein coat). Plant viruses contain RNA but in cauliflower mosaic virus contain DNA. Bacteriophages contain DNA and almost half animal viruses contain RNA and half contain DNA. But it is called that often animal viruses contain DNA. Cancer causing viruses reovirus contain both RNA and DNA, Only some enzymes are detected in viruses such as — Lysozyme in bacteriophages, transcriptase in vaccinia virus, reverse transcriptase and DNA or RNA polymerase in retroviruses.

Table: 1.5-1 Nucleic acid in viruses and no. of strands

DNA Viruses	Strands	RNA Viruses	Strands
Adenoviruses	DNA (2)	Avian leukemia virus	RNA (1)
Bacteriophage \$\phi X 174	DNA (1)	Bacterial virus F2	RNA (1)
Bacteriophage M13	DNA (1)	Bacteriophage MS-2	RNA (1)
Coliphage lambda (λ)	DNA (2)	Coliphage R17	RNA (1)
Coliphage T2, T4, T6	DNA (2)	Influenza virus	RNA (1)
Coliphage T3, T7	DNA (2)	Poliomyelitis virus	RNA (1)
Pox virus	DNA (2)	Tobacco mosaic virus (TMV)	RNA (1)
Herpes viruses	DNA (2)	Reovirus	RNA (2)
Popilloma virus	DNA (2)	Rice dwarf virus	RNA (2)
Polyoma virus SV 40	DNA (2)	Wound Tumour virus	RNA (2)

- (iv) Shape: There is variation in shapes of viruses. On the basis of shape of viruses have been placed in the following categories.
- (a) Straight, rigid rods with helical architecture, e.g. TMV, Barley stripe mosaic virus (BSMV).
- (b) Long flexous thread-like rods, e.g. Potato latent mosaic, Wheat streak mosaic virus.
- (c) Polyhedral virions, e.g. Turnip yellow mosaic, Tobacco ring spot virus.
 - (d) Tadpole like Bacteriophages.
 - (e) Spherical Influenza virus.
- (v) **Size**: Viruses have a long range of size. They range from $10~\text{m}\mu$ to more than $300~\text{m}\mu$ in size. The virus of foot and mouth disease (FMD) of animals is smaller than the largest protein molecule. Largest virus is smallpox virus variola (250 m μ).

(vi) General structure of virus

Structurally viruses are made up of envelope, capsid, nucleoid and occasionally one or two enzymes.

Envelope: Some viruses possess an outer thin loose covering, called envelope. It is composed of proteins (from virus), lipids and carbohydrates (both from host). It is found in some animal viruses e.g., Herpes virus, HIV. The smaller subunits of envelope are called **peplomers** The viruses, which do not possess envelope, are called naked.

Capsid: It is the protein coat that surrounds the central portion of nucleoid and enzymes (if present). The capsid consists of a specific number and arrangement of small sub-units called capsomeres. These sub-units possess antigenic properties.

Nucleoid: The nucleic acid present in the virus is called nucleoid. It is the infective part of virus which utilizes the metabolic machinery of the host cell for synthesis and assembly of viral components. The genetic material of viruses are of four types:

- (a) Double stranded DNA (ds DNA) e.g., Herpes virus, Hep. B virus.
- (b) Single stranded DNA (ss DNA) e.g., Coliphage.
- (c) Double stranded RNA (ds RNA) e.g., Wound tumour virus.
- (d) Single stranded RNA (ss RNA) e.g., Retrovirus, TMV, Polio virus.
- (vii) Life cycle: The word reproduction is not appropriate in case of viruses because they have no cellular components or cell organelles. They do not reproduce themselves but divide by a special mechanism as follows.

Attachment : The bacteriophage gets attached to bacterial cell wall with the help of caudal fibres.

Penetration: Bacteriophage dissolves the bacterial wall by an enzyme *Lysozyme* and makes a pore in cell wall. Through this pore DNA molecule enters in the cell after contraction of head protein, entire protein coat remains outside.

Latent period: Phage DNA controls hosts cellular machinery. Instead of formation of bacterial protein, phage protein formation begins. Cellular DNA and RNA is broken down and from this cellular DNA, phage DNA is formed. Now protein covers the DNA fragments to form a kid virus.

Maturation : This young virion is changed into an adult virus hence this process is called maturation.

Release: The viruses are mature, cell wall of bacterial cell is weakened by enzyme lysozyme. The release of viruses takes place by bursting of host cell and these are again ready for next infection or attack on other bacteria.

(viii) Economic importance of viruses

Uses of viruses

- (a) Specific viral strains are cultured and attenuated to be used as vaccines against specific diseases.
- (b) The addition of cyanophages LPP-1 and SM-1 are useful in controlling water blooms.
- (c) Bacteriophage was used by Hershey and Chase to prove that DNA is the chemical basis of heredity.

106 Viruses

- (d) Bacteriophages are of interest to geneticists because these bring about transduction.
- (e) Water of river Ganga is believed to have phages which destroy bacteria. That is why its water does not get spoiled.

Tobacco mosaic virus (TMV): It was discovered by the Russian worker D. Ivanowski. Franklin etal (1957) described the ultrastructure of (TMV) – It is a rod–shaped virus having a central core of RNA surrounded by protein coat (capsid) to form the nucleocapsid. The nucleocapsid may be naked or may be surrounded by a loose membranous envelope. The protein coat (capsid) consists of 2130 identical subunits (capsomeres).

Bacteriophage: The viruses which attack bacteria are called bacteriophages. In outline they look like tadpole or sperm. The body can be divided into a hexagonal head neck and a tail. The hexagonal head has a central core of DNA, which is surrounded by protein coat. The DNA is double helix. The cylindrical tail is hollow and is entirely made up of proteins. At the end of this, there are six long threads called tail fibres or caudal fibres. These fibres help the virus while attaching to bacteria. Bacteriophage contain lysozyme enzyme.

Cyanophages: Generally some of the viruses are found which attack on blue green algae. Sofferman and Morris (1963) reported 11 filamentous forms of blue green algae (Lyngbya, plectonema and phormidium, hence called LPP-1) which were attacked by viruses. These viruses are usually called cyanophages. Cyanophages contain DNA as their genetic material. These viruses resemble with bacteriophages in morphology and behaviour.

Mycophages: Some fungi such as, Mushrooms, Penicillium, etc have also been found to be infected by viruses. These are isometric in shape and contain double stranded RNA.

Phycophages: These are virus which attack on Algae.

Viroids: Diener and Raymer (1967) discovered very simple smallest infectious agents called Viroids. Viroids consist of RNA only and capsid is lacking. Viroids contain only very low mol. weight. Diener and Raymer reported that causal agent of potato spindle tuber disease was a free RNA and no viral nucleoprotein particles were present in the infected tissue. T.O. Diener (1971) termed it viroid. Viroids are single-stranded, covalently closed circular as well as linear RNA molecules. Transmission is mechanical. The symptoms on host plants are almost similar to those of viruses. Viroids cause persistent infections. A number of other diseases caused by viroids are -Cadang Cadang of coconut, Cucumber pale fruit, Chrysanthemum stunt, Avacado sunblotch, etc.

Prions: Prusiner (1982) discovered it as a human disease causal agents. Stanley B. Prusiner discovered infectious agents

which were prions. Prions are proteinaceous particles thought to cause a number of diseases including the slow virus diseases, therefore also called as **slow viruses**. They are made of protein molecules only. Genetic material (DNA and RNA) is absent in prions. *Kuru*, a disease of central nervous system found in few canniblastic tribes of *New Guinea* is caused by prions.

Interferons: G.M. Findley and McCallum (1937) reported a phenomenon called viral interference in which the cell infected with one type of virus becomes resistant to super infection by other viruses. Alliac Issacs and Lindeman (1957) gave the term interferons to the chemical substances responsible for viral interference.

- Interferons are produced by cells in mammals, rodents, birds, etc., and provide resistance against viruses.
- (ii) Interferons are protein molecules or polypeptides of low molecular weight which prevent viral multiplication.

Table: 1.5-2 Families of animal viruses, grouped by type of nucleic acid

Family	Virion Structure	Diameter (nm)	Examples (Diseases)
dsDNA			
Papova virus	Naked polyhedral	40-57	Papilloma (human warts, cervical cancer); polyoma (tumors in certain animals).
Adeno virus	Naked polyhedral	70 – 80	Viruses that cause respiratory disease; some that cause tumors in certain animals.
Herpes virus	Enveloped polyhedral	150-250	Herpes simplex I (cold sores); herpes simplex II (genital); varicella zoster (chicken pox, shingles); Epstein—Barr virus (infectious mononucleosis, Burkitt's lymphoma).
Pox virus	Enveloped complex	200-350	Variola (smallpox); vaccinia; cowpox.
ss DNA			
Parvo- virus	Naked polyhedral	18-26	Most depended on co infection with adenoviruses for growth

Table: 1.5-3 ss RNA that can serve as mRNA (+ strand RNA)

	, , ,	suanu niva)	DETERMINATE HIS
Picorna virus	Naked polyhedral	18-38	Poliovirus; rhinovirus (commor cold); enteric viruses
Toga virus	Enveloped polyhedral	40-60	Rubella virus; yellow fever virus; encephalitis virus (transmitted by insects).
Retrovirus	Enveloped polyhedral; two copies of genome per virion.	100–120	RNA tumor viruses (solid tumors and leukemia); AIDS

Table: 1.5-4 ss RNA that is a template for mRNA
(- strand RNA)

		straine Itiars)	
Rhabdovir us	Enveloped helical	70–180	Rabies
Paramyxo virus	Enveloped helical	150-300	Measles, mumps
Orthomyx ovirus	Enveloped helical; RNA in eight segments.	80–200	Influenza viruses
ds RNA	SECTION 1		Bustano to
Reovirus	Naked polyhedral; RNA in ten segments.	60–80	Diarrhoea viruses

*ds = double- stranded; ss = single-stranded.

Table: 1.5-5 Important plant diseases caused by viruses

S.No.	Disease	Causal organism
(1)	Abutilon mosaic	Abutilon mosaic virus
(2)	Bunchy top of banana	Banana bunchy top virus
(3)	Cucumber mosaic	Cucumber mosaic virus
(4)	Little leaf of brinjal	Brinjal little leaf virus
(5)	Little leaf of cotton	Cotton little leaf virus
(6)	Papaya mosaic	Papaya mosaic virus
(7)	Potato leaf roll	Potato leaf roll virus
(8)	Potato mild mosaic	Potato virus X
(9)	Potato rugose mosaic	Potato virus X and Y
(10)	Stunt of S. C.	Ratoon stunt virus
(11)	Rosette of groundnut	Groundnut mosaic virus
(12)	Sugarcane mosaic	Sugarcane virus I
(13)	Tobacco mosaic	Tobacco mosaic virus
(14)	Tomato leaf curl	Tomato curl virus
(15)	Tristeza of citrus	Citrus Tristeza virus

Table: 1.5-6 Important human diseases caused by viruses

S.No.	Disease	Host	Causal organism
(1)	Encephalitis	Man	Encephalitis virus
(2)	Infectious hepatitis	Man	Hepatitis virus
(3)	Herpetic Keratitis	Man	Herpes virus
(4)	Influenza	Man	Influenza virus-a
(5)	Measles	Man	Measles virus
(6)	Viral bronchitis	Man	Parainfluenza virus
(7)	Poliomyelitis	Man (children)	Polio virus
(8)	Small Pox	Man	Pox virus
(9)	Common cold	Man	Rhino virus
(10)	Yellow fever	Man	Yellow fever virus

Tips & Tricks

- Father of Virology W.M. Stanley (American Microbiologist).
- Edward Jenner (1796) developed the first successful vaccine against viral disease small pox.
- ∠ D' Herelle (1917) coined the term "bacteriophage" for bacterial virus.
- E Caulimo virus (cauliflower mosaic virus) are double stranded DNA virus
- ∠ Lindemann (1957) did the first successful vaccination against Polio.
- Single virus observed under electron microscope, outside host is called "Virion".
- The first virus to be cultured in human cells was Polio virus.
- Most of the phase are DNA virus.
- Retroviruses and reverse transcription were reported by Temin and Baltimore.
- ✓ Viruses can pass through bacteria proof filters. These are
 the intermediate connection between living and non living.
- Viruses have host specificity. A specific virus infects only a particular host.
- In the world which do not have cell are virus, viroids and prions.
- The synthesis of viral proteins takes place on host ribosomes.
- Viruses lack pigments metabolic activity, they are made up of RNA the only movement and sex organ, but some enzymes are found in them.
- AIDS is caused by HIV. It infects T-lymphocytes, HIV virus remains dormant for about 8 years, Infected person does not suffer a symptoms during this period. AIDS day is 1st December.
- Size of virus is 20 nm 300 nm Largest virus is vaccinia or cow pox-virus (500nm). Smallest virus is Alfa-alfa virus (17 nm).
- Pox virus is also known as vip virus.
- Five genes are present in a simplest virus.

Objective Questions

Viruses

1. The first to isolate plant virus was

[NCERT; CBSE PMT 1993]

Or

The Tobacco mosaic virus was crystallized for first time by

[MP PMT 1994]

(a) W.M. Stanley

(b) E. C. Stackmann

(c) A. K. Smith

(d) Ivanowski

2. The viruses contain

INCERT: J & K CET 2008]

(a) Proteins only

(b) DNA only

(c) Nucleic acids only

(d) Proteins, DNA or RNA (nucleic acids)

 Caulimo virus (Cauliflower mosaic virus) are a group of viruses which have

(a) Double stranded RNA

(b) Single stranded RNA

(c) Single stranded DNA

(d) Double stranded DNA

4. The rabies virus consists of

[WB JEE 2009]

(a) Single stranded RNA

(b) Double stranded RNA

(c) Single stranded DNA

(d) Double stranded DNA

 A virus containing ssRNA act as a template for DNA sunthesis is called as

[MP PMT 2007; DPMT 2007; Odisha JEE 2008]

(a) Polio virus

(b) Retro virus

(c) Pox virus

(d) Adeno virus

6. Viruses enter plant cells only through...... [VITEEE 2008]

(a) Lenticels

(b) Wounds

(c) Stomata

(d) Roots

7. Influenza virus has got

(a) Naked capsid

(b) Enveloped capsid

(c) Naked polyhedral capsid (d) No capsid at all

8. The genetic material in viruses is

NCERT; CPMT 1994;

MP PMT 1995, 98, 2000; CBSE PMT 1997; Рь. PMT 2000; BHU 2005]

(a) Only RNA

(b) Only DNA

(c) RNA and DNA both

(d) RNA or DNA i.e. one nucleic acid in a virus

Each capsomere of TMV contain amino acids whose number is

(a) 158

(b) 185

(c) 815

(d) 581

10. Ribovira is a group of viruses which contains

(a) dsDNA

(b) ssDNA

(c) RNA

(d) None of these

11. Which of the following is the smallest virus

(a) Foot and mouth virus

(b) Tobacco mosaic virus

(c) Coliphage lambda virus

(d) Wound tumour virus

12. Which of the following is the largest virus

(a) Penicillium virus

(b) Wound tumour virus

(c) Pox virus

(d) None of the above

13. Which of the following is false

[CBSE PMT 2005; DUMET 2009]

(a) Most plant viruses are RNA viruses

(b) Most animal viruses are DNA viruses

(c) TMV has double stranded RNA molecule

(d) T₄ bacteriophage has double stranded DNA molecule

14. Which one is absent in viruses

[AFMC 2008]

(a) Replication

(b) Protein synthesis

(c) Energy liberation

(d) Mutation

15. Wound tumour virus has

(a) Double stranded DNA

(b) Single stranded DNA

(c) Double stranded RNA

(d) Single stranded RNA

Which of the following is a DNA containing plant virus

[Pb. PMT 1999, 2000]

[CBSE PMT 1993]

(a) Tobacco mosaic virus

(b) Tomato mosaic virus

(c) Cauliflower mosaic virus (d) Potato mosaic virus

17. Algal viruses are known as

(b) Cyanophages

(a) Binal viruses(c) Mycophages

(d) Phycophages

18. Arthropod borne viruses are

(a) Ribo virus

(b) Reo virus

(c) Arbo virus

(d) None of these

 Which one of the following are intracellular obligate parasites [KCET 1998; DUMET 2009]

(a) Bacteria

(b) Viruses

(c) Slime moulds

(d) Blue-green algae

20. Select the wrong statements

[AIPMT 2015]

(a) W.M. Stanley showed that viruses could be crystallized

(b) The term 'contagium vivum fluidum' was coined by M.W. beijerinck

(c) Mosaic disease in tobacco and AIDS in human being are caused by viruses

(d) The viroids were discovered by D.J. Ivanowski

21. Helper virus is called

(a) Perfect phage of virus

(b) A defective phage which helps another defective phage

(c) A latent phage

(d) None of these

22. Who discovered interferons

(a) Issacs and Lindmann

(b) Holmes and Knight

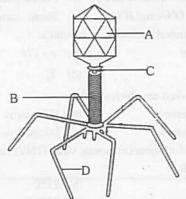

(c) Harshey and Chase

(d) Enders

(b)	Sheath	Collar	Head	Tail fibres
(c)	Head	Sheath	Collar	Tail fibres
(d)	Collar	Tail fibres	Head	Sheath

Viruses usually infect the whole plant except the

[CBSE PMT 1993; MH CET 2000]

- (a) Stem apex
- (b) Cortex
- (c) Pith
- (d) Phloem
- Potato tuber spindle disease is caused by 54

[MP PMT 2007; DUMET 2009; BHU 2012]

- (a) Virus
- (b) Viroid
- (c) Plasmid
- (d) None of these
- Which one the following viruse contains both DNA and RNA [WB JEE 2010]
 - (a) Cyanophage
- (b) Herpes virus
- (c) Leuko virus
- (d) Polio virus
- Grey matter of brain is affected by
 - (a) Measel virus
- (b) Varicella virus
- (c) Dengue fever virus
- (d) Encephalitis virus
- 57. X-bodies are formed during infection of
 - (a) Bacteria
- (b) Mycoplasma
- (c) Virus
- (d) All the above
- Infectious proteins are presents in

[MP PMT 2007; CBSE PMT (Pre.) 2010]

- (a) Satellite viruses
- (b) Gemini viruses
- (d) Viroids
- Our crops suffer from many diseases. Indicate the disease 59. caused by virus

 - (a) Potato mosaic (b) Citrus canker
 - (c) Brown rot of potato (d) Leaf spot of cotton

- Banana bunchy top is caused by 60

- (a) Mycoplasma
- (b) Deutromycetes
- (c) Xanthomonas
- (d) Pentalonia nigronervosa (Virus)
- Interferon suppresses the pathogenic activity of 61.

ICMC Vellore 1994; MP PMT 1998; MHCET 2000; BVP 2000, 04]

- (a) Bacteria
- (b) Viruses
- (c) Protozoans
- (d) Helminths
- Tobacco mosaic Virus (TMV) has 62.

[EAMCET 1993, MHCET 2001; MP PMT 2001; BVP 2002; AIEEE Pharmacy 2004; J & K CET 2008]

- (a) A single stranded RNA molecule
- (b) A double stranded RNA molecule
- (c) A single stranded DNA molecule
- (d) A double stranded DNA molecule
- Viruses that infect bacteria, multiply and cause their lysis, [CBSE PMT 2004; AIIMS 2009] are called
 - (a) Lytic

65.

- (b) Lysogenic
- (c) Lysozymes
- (d) Lipolytic
- Phages that show lysogenic cycle are called 64.

[MP PMT 1997; VITEEE 2008]

[MP PMT 1995, 98, 2002, 10, 12;

- (a) Temperate phages
- (b) Virulent phages
- (c) Avirulent phages A bacteriophage is
- (d) Lytic phages
- MHCET 2000; Odisha JEE 2009; WB JEE 2010]

- (a) A virus attacking a bacterium
- (b) A bacterium attacking a virus
- (c) A stage in the life-cycle of bacterium
- (d) A virus attacking another virus
- Tailed bacteriophages are 66.
 - (a) Motile on surface of bacteria

 - (b) Non-motile
 - (c) Actively motile in water
 - (d) Motile on surface of plant leaves
- Which of the following is a pandemic disease 67.
 - (a) Amoebic dysentry
- (b) Hepatitis
- (c) Filariasis
- (d) Influenza
- Sometimes when a virus attacks a bacterium, neither the virus multiplies nor the bacterium dies. This phenomenon is called as [MP PMT 1998]
 - (a) Adsorption
- (b) Assimilation
- (c) Lysogeny
- (d) Viral stability
- On the basis of host attacked viruses are classified into

[MP PMT 1995]

[CBSE PMT 1995]

- (a) Two types
- (b) Three types
- (c) Four types
- (d) Five types

- The virus of deoxyvira (sub-phylum) contains
 - (a) mRNA
- (b) tRNA
- (c) DNA
- (d) rRNA
- An extreme example of latency in which DNA of the phage 93. is integrated with the DNA of host cell chromosome is
 - [DPMT 1993]

- (a) Lysis
- (b) Lysogeny
- (c) Attenuated virus
- (d) Prophage
- In cyanophage, the genetic material is
 - (a) RNA
- (b) DNA
- (c) RNA and DNA
- (d) Protein
- 95. Satellite virus is a
 - (a) Independent virus
 - (b) Associated with an activator virus
 - (c) Both (a) and (b)
 - (d) None of these
- 96. Ultrastructure of bacteriophage-T was studied by
 - (a) R.L. Sinsheimer
- (b) S. Brenner
- (c) M. Schlesinger
- (d) None of the above
- The water of Holy Ganga, river is pure due to the presence 97. [MP PMT 1998]
 - (a) Cyanophages
- (b) Hydrophytes
- (c) Bacteria
- (d) Bacteriophages
- 98. Viroids have

[MHCET 2001; AIEEE Pharmacy 2004; J & K CET 2012]

- (a) Double stranded RNA enclosed by protein coat
- (b) Double stranded DNA enclosed by protein coat
- (c) Single stranded DNA not enclosed by protein coat
- (d) Single stranded RNA not enclosed by protein coat
- Which statement is wrong for viruses

[CBSE PMT (Pre.) 2012]

- (a) All are parasites
- (b) All of them have helical symmetry
- (c) They have ability of synthesize nucleic acids and proteins
- (d) Antibiotics have no effect on them
- 100. The genome of transducing phages is [JIPMER 2001]
 - (a) Single stranded RNA
- (b) Double stranded RNA
- (c) Single stranded DNA
- (d) Double stranded DNA
- 101. A single stranded DNA molecule is the genetic material of [BHU 1995, 2000; MHCET 2000; bacteriophage **DPMT 2003, 04]**
 - (a) T2

- (b) T₄
- (c) Ø× 174
- (d) \(\lambda\)
- 102. Which of the following diseases are known to be caused by viruses (In this item one or more of the answers given may be correct. Decide which are correct and mark the answer sheet according to the code)
 - Burkitt's lymphoma
 - 2. Adult T-cell leukemia
 - 3. Phenyl ketonuria

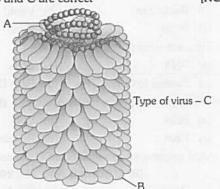

Code

- (a) 1, 2 and 3 are correct
- (b) Only 1 and 2 are correct
- (c) Only 2 and 3 are correct (d) Only 1 and 3 are correct

- 103. Which of the following statements is not true for retroviruses [CBSE PMT 2004]
 - (a) The gentic material in mature retroviruses in RNA
 - (b) Retroviruses are causative agents or certain kinds of cancer in man
 - (c) DNA is not present at any stage in the life cycle of retroviruses
 - (d) Retroviruses carry gene for RNA-dependent DNA polymerase
- 104. In phage (plaque) culture

[CMC Vellore 1993]

- (a) Only protein of virus enters and multiplies
- (b) Only DNA of virus enters the bacterium and multiplies
- (c) Whole virus enters the bacterium and multiplies
- (d) None of these
- 105. Satellite RNA are present in some [NEET (Karnataka) 2013]
 - (a) Viroids
- (b) Prions
- (c) Bacteriophages
- (d) Plant viruses
- 106. The diagram of a virus is given below. In which of the [NCERT] options A, B and C are correct

	A	В	C
(a)	RNA	Protein	HIV
(b)	RNA	Lipid	Tobacco Mosaic Virus
(c)	DNA	Capsid	Tobacco Mosaic Virus
(d)	RNA	Capsid	Tobacco Mosaic Virus

107. Which of the following statements is wrong for viroids

[NEET (Phase-I) 2016]

- (a) They lack a protein coat
- (b) They are smaller than viruses
- (c) They cause infections
- (d) Their RNA is of high molecular weight
- 108. The genome of Influenza virus is a

- (a) Single-stranded RNA (-) (b) Single-stranded RNA (+)
- (c) Double-stranded RNA
- (d) Single-stranded DNA

Critical Thinking Objective Questions

- Viruses are non-cellular organisms but replicate themselves once they infect the host cell. To which of the following [NCERT] kingdom do viruses belong to
 - (a) Monera
- (b) Protista
- (c) Fungi
- (d) None of the above

- 2. What is the purest form of matter that cannot be separated into different substances by chemical means
 - (a) Electrons
- (b) Molecules
- (c) Elements
- (d) Compounds
- Bacteriophage is similar to fungus 3.
 - [CMC Vellore 1993] (a) In having DNA as genetic material
 - (b) In having RNA as genetic material

 - (c) In mode of reproduction
 - (d) In having cell wall
- 4. Interferon is a [MP PMT 1996, 2006; Pb PMT 2000; CBSE PMT 2000, 01; AFMC 2002; DPMT 2003; BHU 2003; MHCET 2003; KCET 2007; VITEEE 2008]
 - (a) Low molecular weight protein which inhibits viral multiplication
 - (b) RNA used for DNA synthesis
 - (c) Protein used for the transportation of oxygen
 - (d) Protein inhibits DNA synthesis
- Which one of the following enzymes is present in the 5. bacteriophage [MP PMT 1996]
 - (a) Protease
- (b) Lysozyme
- (c) Succinic dehydrogenase (d) Urease
- 6. AIDS virus contains or Human immuno deficiency (HIV) virus has protein coat and genetic material which is

[MP PMT 1994, 99, 2003, 09; CBSE PMT 1998; AIIMS 2000, 13]

- (a) Single stranded RNA with protein
- (b) Double stranded RNA
- (c) Single stranded DNA with protein
- (d) Double stranded DNA
- 7. Viruses have

[CBSE PMT 2014]

- (a) Single chromosome
- (b) Both DNA and RNA
- (c) DNA enclosed in a protein coat
- (d) Prokaryotic nucleus
- Difference between Virus and Viroid is 8.

[NCERT]

- (a) Absence of protein coat in viroid but present in virus
- (b) Presence of low molecular weight RNA in virus but absent in viroid
- (c) Both a and b
- (d) None of the above

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason (a) is a correct explanation of the assertion
- If both the assertion and reason are true but the reason is (b) not a correct explanation of the assertion
- If the assertion is true but the reason is false (c)
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true

Assertion

Interferons are a type of antibodies produced by body cells infected by

Reason

Interferons stimulate inflammation at the

site of injury.

[AIIMS 2008]

2. Assertion DNA serves as hereditary material.

Reason

DNA functions as blue-print for building

and running cellular machinery.

Assertion

Primitive atmosphere was formed by the

lightest atoms.

Reason

The primitive atmosphere was reducing in

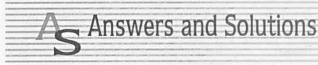

nswers

Viruses

- 19. (b) Viruses are non-cellular, infectious, obligate, intracellular parasites. These are genetic elements (DNA or RNA) wrapped in a protein coat and are not considered to be organisms, as they can not reproduced independently.
- 21. (b) Helper virus needs another virus to be active.
- **30.** (d) Viruses are made up of proteins and nucleic acids while viroids are naked RNA molecules.
- **39.** (b) Single stranded DNA found in e.g. $\phi \times 174$, S–13, F–1, M–13, R_{17} (*Parvo* viruses) etc.
- (c) Temin and Baltimore (1975) discovered the process of reverse transcription. It is found in retrovirus.
- (b) The protein coat (capsid) consists of 2130 identical subunits (capsomeres) in TMV.
- 43. (a) Because viruses are obligate parasites, so that they can only survive in living cells not in non-livings.
- 46. (b) Influenza is caused by virus. It is a RNA virus with a helical capsid surrounded by an envelope with spike.
- 51. (b) Retrovirus is an RNA containing virus that converts its RNA into DNA by means of the enzyme reverse transcriptase; this enables it to become integrated into its host's DNA. The best known retrovirus is HIV, responsible for AIDS in humans.
- 52. (c) A Head; B Sheath; C Collar; D Tail fibre
- **53.** (a) Because in apical tips of shoot apex, a few growth hormones like auxins are formed which check infection of viruses.
- **55.** (c) Leuko virus (a Retro virus) posses both *DNA* and *RNA* in their life cycle.
- **56.** (d) Encephalitis virus infects the grey matter of brain and cause swelling in brain known as brain fever.
- 61. (b) Interferon: In 1957 Issac and Lindeman called interferon to that protein, which is synthesized in human cells during viral infections. This protein provide immunity to the same virus or the others also.
- 75. (b) Viral genome incorporated into host DNA is called prophage. Most of the prohage genes are repressed by two repressor proteins that are the product of phage genes.
- 78. (c) Bacteriophage is a virus which infect bacteria. In its tadpole like structure, DNA is found inside the proteinous head.

- 83. (c) Rous sarcoma virus: This virus related to retro group of viruses is having genetical material RNA. But this RNA on reaching in host cell synthesize DNA by the process of reverse transcription, which form mRNA and then protein. So the sequence in this is [RNA → DNA → mRNA → Protein]
- 84. (d) RNA is single stranded helically coiled with 6400 ribonucleotides.
- 86. (d) Lysogenic cycle is the reproductive cycle of a temperate, nonvirulent phage (like λ phage) which has the potential to lyse the host cell but normally involves integration of viral genome with host DNA and multiplication of the same alongwith the host cell.
- **93.** (b) Lysogeny: The process in which bacteriophage attacking on host bacteria, after transduction burst the bacterial cell is called as lysogeny.
- 95. (b) Satellite virus: This virus carry some other viruses on his body and behaves like carrier e.g. tobacco mottle virus.
- **101.** (c) $\phi \times 174$ Bacteriophage: In this bacteriophage, DNA is rounded, closed and bangle shaped, the duplication pattern is different type in this bacteriophage.

Critical Thinking Questions

- (c) An element is the simplest form of matter which cannot be split into two or more simpler substances by ordinary chemical methods because an element is formed of only one type of atom.
- 4. (a) Interferon: During infection of viruses on human cells, a protein having 270 amino acids is synthesized known as interferon. This protein helps in developing defence mechanism against the same virus or others also.
- (b) In bacteriophage, enzyme lysozyme helps at the time of dissolving host wall.
- (a) HIV virus is a retrovirus which contains single stranded RNA surrounded by protein coat (core shell) as genetic material. It causes AIDS.
- 7. (c) Nucleoprotein particles.

Assertion and Reason

- 1. (d)
- 2. (a) DNA is the genetic material in most of living organism except the plant viruses and some bacteriophages. It is the only molecule which can replicate itself or can form its own carbon copy. The phenomenon is called molecular reproduction. All the information required for growth, differentiation, running cellular machinery and reproduction is contained in DNA molecules. These genetic information of DNA are like the blue print. During cell division (which involve DNA replication) the daughter cell receive the same blue print or genetic material as in the parental cell.
- 3. (b) The lightest atoms of nitrogen, hydrogen, carbon etc. formed the primitive atmosphere. Hydrogen atoms were most numerous and most reactive in primitive atmosphere. First hydrogen atoms combined with all oxygen atoms to form water and leaving no free oxygen. Thus primitive atmosphere was reducing atmosphere (without free oxygen) unlike the present oxidising atmosphere (with free oxygen). Presence of huge amount of free hydrogen in primitive atmosphere also proves its reducing nature.

ET Self Evaluation Test

- Identify the correct sequence of events in the viral replication process.
 - I. Eclipse
- II. Maturation
- III. Adsorption
- IV. Assembly
- V. Penetration

Characteristics of Plantae

The term plant is more commonly used for land photoautotrophs with distinct root, stem and leaves. Study of plants is called phytology.

Kingdom plantae includes green, brown and red algae, liverworts, mosses, ferns and seed plants with or without flowers. They have the following characters.

- (1) Member of the kingdom are multicellular, eukaryotes. However, unicellular and colonial members of green and red algae are also included in kingdom plantae.
 - (2) Cells are surrounded by cell wall. It contain cellulose.
 - (3) Mature cells usually possess a single central vacuole.
- (4) Reserve food is starch in green algae and embryophytes, floridean starch in red algae and laminarin in brown algae.
 - (5) They contain photosynthetic pigment in plastids.
- (6) Principal mode of nutrition is photosynthesis but number of plants have become absorptive.
- (7) In lower member, organization is protoplasmic or cellular. In higher forms, the organization is of tissue and organ level.
 - (8) Branches are present. Therefore body form is irregular.
- (9) Growth occur due to presence definite growing points or cells. In higher forms, growing areas called meristems.
- (10) Locomotion is absent except in some unicellular colonial forms. Multicellular members are sedentary or fixed.
 - (11) The cells often contain inorganic crystals of different salts.
 - (12) Vegetative reproduction is quite common.
- (13) Asexual reproduction is found in algal group and occur by means of spores.
- (14) There is a progressive evolution in sexual reproduction. The reproductive organs are multicellular.
- (15) A multicellular embryo is formed during development from the zygote. Algae lack embryo stage. Life cycle consists of alternating haploid gametophyte and diploid sporophyte generation. This phenomenon is called alternation of generation.

Classification of plantae

August Wilhelm Eichler (1883) a Vinnese botanist, divided plant kingdom into two subkingdoms mainly on the basis of presence or absence of seeds.

- (1) **Cryptogamae** (Gr. *Cryptos* = hidden; *gamos* = marriage) : Lower plants in which sex organs are hidden and seeds and flowers absent. It includes **Thallophytes**, **Bryophytes**, **Pteridophytes**.
- (2) **Phanerogamae** (Gr. *Phaneros* = visible; *gamos* = marriage) : Higher plants in which sex organs are evident; seeds present. It includes Gymnosperms and Angiosperms.

Engler (1886) divided plants into Thallophyta (plant body thallus like and there is no embryo formation) and Embryophyta (zygote develops into multicellular embryo).

Thallophyta (Gr. Thallos = undifferentiated; phyton = plant). This term was coined by Endlicher (1836). It includes Algae, Fungi, Bacteria, Lichens. Unger (1838) placed algae, fungi and lichens under thallophyta. In modern system of clasification like Whittaker (1969), Fungi, Lichens and Bacteria are excluded from this group and are placed in separate kingdoms.

Algae

(Gk. Phycos = alga or sea weed)

The branch of botany dealing with the study of algae is called as **phycology** or **algology**. They are simple, thallose, autotrophic non-vascular plants having unicelled sex organs and no embryo formation. In Whittaker's classification, algae are grouped in three kingdom – Monera (blue green algae), Protista (dinoflagellates, diatoms, euglenoids) and Plantae (green algae, red algae and brown algae).

According to Fritsch (Father of algalogy), (1935) the designation alga must include all holophytic organisms, as well as their numerous colourless derivatives, that fail to reach the level of differentiation characteristic of archegoniatae plants.

Occurrence : The algae occur in a variety of habitats which are summarised here under :

Fresh water forms: They occurs in rivers, ponds, pools, lakes and ditches. Those forms which remain attached to bottom soil are called as epipelic. Several forms remain attached to bottom or at the bank or to submerged objects. They are described as benthos. Many forms remain attached to rocks or stones. They are described as epilithic or lithophytic. e.g., Batrachospermum.

Marine forms: Most of the members of brown algae, red algae some green and blue-green algae occur in sea. While some occur as phytoplanktons and benthos, others occur as lithophytes. The giant forms like Macrocystis (60 meters) and Nereocystis (50 meters) are also marine.

Terrestrial forms: Several members of green and bluegreen algae and a few others occur on damp soil. While forms like Oscillatoria and Nostoc occur on alkaline and calcareous soil, Fritschiella grows on acidic soil. Xanthophyceae members like Vaucheria and Botrydium growing on damp shady soil or on shady walls, are often described as Saprophytes.

Specialized habitats

Cryophytes: Plants growing on snow or ice are called as **cryophytes**. Different algal forms produce a specific colour effect while growing as cryophyte e.g., yellow-green by Chlamydomonas yellowstonensis, red by C. nivalis, black by Scotiella nivalis and purple-brown by Ancylonema nordenskioldii.

Thermophytes: Plants growing in hot water are called as **thermophytes**. Some blue-green algae grow in hot water springs at about 70°C e.g., Oscillatoria brevis.

Epiphytes : Several algal forms grow on other plants (algae, angiosperms) as epiphytes. e.g., Oedogonium, Cladophora, Vaucheria etc.

Endophytes: Some blue-green algae grows as endophytes inside other plants e.g., Anabaena growing inside the leaf of Azolla (fern), Nostoc inside the thallus of Anthoceros (hornwort) and Anabaena, Nostoc, Oscillatoria inside the coralloid roots of Cycas.

Epizoic: Algae growing on the bodies of animals are described as epizoic. e.g., Cladophora crispata grows on snail shell, Characium grows on the antennae of mosquito larvae, Cyanoderma (red alga) and Trichophilus (green alga) are grows on scales of sloth.

Endozoic : Algae growing inside the body of animals. *e.g.*, *Chlorella* grow within the tissue of *Hydra*. Some blue-green algae also grow in the respiratory tract of animals. The blue-green algae which grow endozoically inside the protozoans are called as cyanellae.

Symbiotic forms: Some algae like *Chlorella*, *Nostoce*. etc. growing in symbiotic relationship with members of Ascomycetes and Basidiomycetes (Fungi) constitute the lichen.

Some species of Cladophora live in symbiotic association in a sponge Eplydatea.

Parasites : The alga Cephaleuros virescens grows as a parasite on the tea leaves. In addition, Rhodochytrium, Phyllosiphon are other parasitic algal forms.

Phyllobium sphagnicolum is parasite on Sphagnum (moss).

Thallus organization

The algae show a considerable variation in the organization of the thallus:

- (1) Unicellular forms: Several members of algae are unicelled. They may be motile (Chlamydomonas) or non-motile (diatoms). Some forms have a thick wall and become sedentary for certain duration in their life history. They are called as coccoid e.g., Chlorella, Chlorococcus.
 - (2) Multicellular forms: Multicellular forms are following:

Colonial: A colony consists of independent organisms. While the colony of *Volvox* is motile, that of *Hydrodictyon* is fixed. A colony having fixed number of cells and division of labour is called as coenobium *e.g.*, *Volvox*.

Palmelloid : Here the vegetative cells of the alga get surrounded by a mucilagenous matrix e.g., Tetraspora, Aphanotheca.

Dendroid: Here the colony appears like a microscopic tree. There is secretion of mucilage from the polar end *e.g.*, *Ecballocystis*.

Rhizopodial: Cells are united through rhizopodia e.g., Chrysidiastrum.

Filamentous: Most of the algal forms are filamentous. The filaments may be uniseriate or multiseriate, free floating (Spirogyra) or attached (Ulothrix), unbranched (Ulothrix) or branched (Cladophora). The branches may be monomorphic (Cladophora) or dimorphic (Batrachospermum). The branching may be lateral or dichotomous, true (Ectocarpus) or false (Scytonema). The filaments may be monosiphonous (Batrachospermum) or polysiphonous (Polysiphonia). In some filamentous forms there is distinction of a prostrate system and an erect system, thus constituting the heterotrichous habit. e.g., Stigeoclonium.

Siphonous: An aseptate, multinucleate (coenocytic) condition of a filament or thallus constitutes the siphonous habit e.g., Vaucheria.

Parenchymatous: Parenchymatous organization of the thallus has been observed in many members of brown algae (Sargassum, Laminaria), red algae (Gracillaria, Porphyra) and a few green algae (Chara, Ulva) etc.

Cell organization

Most of the algal groups (except blue-green and dinoflagellates) show eukaryotic cell structure. The cell wall is made up of **cellulose**. Some red algae (Corallina) have impregnation of $CaCO_3$. The cells possess a well organised nucleus. The minimum chromosome number in algae is n=2 ($Porphyra\ linearis$) and the maximum number is n=592 ($Netrium\ digitalis$). The cells possess distinct mitochondria, plastids, E.R., ribosomes and golgi body. There may be a single thylakoid in the granum of Rhodophyceae, two in Cryptophyceae, three in Phaeophyceae and Bacillariophyceae but generally many.

The motile forms also possess flagella. They show the usual 9 + 2 structure. They are of two types – **acronematic** (whiplash type) and **pleuronematic** (tinsel type).

Reproduction

The algae reproduce vegetatively, asexually and sexually. Various method involved in reproduction are discussed in the following account.

(1) Vegetative reproduction: It occurs by following types.

Fragmentation: It occurs due to breakage of filament or thallus into fragments, each of which behaves as an independent organism *e.g.*, *Ulothrix*, *Spirogyra* etc.

Fission: The unicelled forms like diatoms, desmids multiply by fission i.e., simple cell division.

Budding: A bud arises as a papilla on the parent cell. It enlarges and finally separates e.g., *Protosiphon*.

Akinetes: Due to deposition of food material followed by thickening of the parent wall, a cell is transformed into an akinete. They may be formed in a chain. On the arrival of favourable conditions, they germinate to form a new plant *e.g.*, *Cladophora*, *Ulothrix*, *Nostoc* etc.

(2) Asexual reproduction: It occurs by the formation of various types of spores in sporangia. Except the zoospores, all other types of spores are non-motile.

Zoospores: These are thin walled motile spores. They are anteriorly biflagellate and the two flagella are similar in Cladophora. In Vaucheria and Ectocarpus they are laterally biflagellate and the two flagella are dissimilar. Multiflagellate zoospores are formed in Oedogonium and Vaucheria. In Vaucheria the flagella are present all over the surface in pairs and hence it is called as synzoospore.

Aplanospores: They are thin walled and non-motile spores commonly formed in *Chlamydomonas*, *Ulothrix* etc.

Autospores : They are also thin walled, non-motile spores which resemble the parent cell *e.g.*, *Chlorella*.

Hypnospores: These are thick walled non-motile spores formed to tide over unfavourable condition. They germinate on the arrival of favourable conditions e.g., Chlamydomonas, Ulothrix.

Carpospores : In red algae, carposporangia are formed at the tip of gonimoblast filaments which produce a single haploid or diploid carpospore *e.g.*, *Batrachospermum*, *Polysiphonia*.

Tetraspores: Four non-motile tetraspores are formed inside a tetrasporangium as a result of mitosis in brown algae (e.g., *Dictyota*) or by meiosis in red algae (e.g., *Polysiphonia*).

Monospore : The juvenile stage of *Batrachospermum*, a red alga, multiplies by forming a single monospore formed in side a monosporangium.

Palmella stage: In dry conditions, zoospores or aplanospores get surrounded by mucilaginous sheath. The divisions continue and they take the shape of colony. This is known as palmella stage. Under favourable conditions each zoospore gives rise to a new plant. e.g., Chlamydomonas.

(3) Sexual reproduction: The sexual reproduction in algae is broadly of three types as under:

Isogamy: It involves fusion of gametes which are morphologically and physiologically similar. They are called as isogametes *e.g.*, *Chlamydomonas eugametos*. In diatoms, there is simplification of isogamous reproduction.

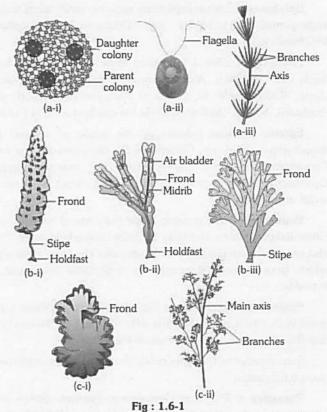

Anisogamy: When the two gametes are morphologically dissimilar, the anisogamy is said to be morphological e.g., Chlamydomonas braunii, Ectocarpus secundus. Here the smaller gamete may be called as male and the large one as female. When the two gametes are morphologically similar but differ in their behaviour, the anisogamy is said to be physiological e.g., Spirogyra, Ectocarpus siliculosus.

Oogamy: In this process there is formation of unicelled sex organs. The male sex organ is called as antheridium and the female as oogonium. The antheridium forms the male gametes called antherozoids which are generally flagellate. The oogonium forms a non-motile female gamete called egg. The oogamy involves fusion of antherozoids with egg. The simplest type of oogamy is seen in Chlamydomonas coccifera.

Important features of some selected classes

Chlorophyceae or Green algae: Plants are fresh water or marine and forms unicelled to parenchymatous. Chief photosynthetic pigments are chlorophyll a, b; α , β , γ - carotenes, lycopene; lutein, violaxanthin. Reserve food is **starch**. Zoospore are formed and male gametes are flagellate. Flagella identical. Sexual reproduction – Isogamous, anisogamous or oogamous type. e.g., Chlamydomonas, Spirogyra.

Xanthophyceae or Yellow green algae: Plants are generally fresh water and forms unicelled to siphonous. Chief photosynthetic pigments are chlorophyll a, e; β -carotene, violaxanthin, neoxanthin. Reserve food is **chrysolaminarin** and **oils**. Zoospore are formed and male gametes flagellate. Flagella non-identical (unequal). Sexual reproduction – Isogamous, anisogamous or oogamous type. e.g., Vaucheria.

Algae : (a) Green algae (i) Volvox (ii) Chlamydomonas (iii) Chara (b) Brown algae (i) Laminaria (ii) Fucus (iii) Dictyota

(c) Red algae (i) Porphyra (ii) Polysiphonia

Phaeophyceae or Brown algae: Plants are marine and forms unicelled to parenchymatous. Chief photosynthetic pigments are chlorophyll a, c; β -carotene, fucoxanthin (brown colour), lutein, violaxanthin, diatoxanthin. Reserve food is laminarin, mannitol and oils. Zoospore are formed and male gametes flagellate. Flagella unequal. Sexual reproduction — Isogamous, anisogamous or oogamous type. e.g., Fucus, Dictyota.

Rhodophyceae or Red algae: Plants are generally marine and forms filamentous to parenchymatous. Chief photosynthetic pigments are chlorophyll a, d is present but chlorophyll c is absent; α , β -carotene, lutein, violaxanthin, fucoxanthin, myxoxanthin, γ -phycocyythrin (red colour), γ -phycocyanin (blue pigment) and allophycocyanin. Reserve food is **floridean starch**, galactan $-SO_4$ polymers. Zoospores are not formed and male gametes are non-flagellate. Sexual reproduction by specialized type of oogamy. Life cycle haplobiontic or diplobiontic. e.g., Polysiphonia, Porphyra.

Myxophyceae or Cyanophyceae: Plants are generally fresh water, a few forms marine and forms unicelled to filamentous. Cells showing prokaryotic organization. Chief photosynthetic pigments are chlorophyll a; β -carotene; lutein, myxoxanthin, oscillaxanthin, c-phycocyanin, c-phycoerythrin, allophycocyanin. Reserve food is cyanophycean starch (glycogen) and cyanophycin (protein). Zoospore are not formed and no flagellate bodies. Sexual reproduction is absent. e.g., Nostoc, Anabaena.

Economic importance

Useful aspects

Nitrogen fixation: Some fifty species of blue-green algae are capable of fixing atmospheric nitrogen in the soil e.g., Anabaena, Aulosira, Cylindrospermum, Nostoc and Tolypothrix etc. Under aerobic conditions, nitrogen is fixed by heterocysts only. Under anaerobic condition the vegetative cells also show nitrogenase activity.

Algae as food: Many green algae such as Chlorella, Ulva, Caulerpa, Enteromorpha, etc. are used as food. Chlorella has about 50% protein and 20% of lipid and carbohydrates. The Chlorella protein contains all the amino acids essential for human nutrition. Ulva lactuca has formerly used in salad and soup in Scotland.

Green algae in space research: In recent years biologists have realized that unicellular green algae (e.g., Chlorella) could be used to provide O_2 during space flight trips.

Antibiotics: The genus Chlorella yields an antibiotic chlorellin, which is used against Gram +ve and Gram -ve bacteria, especially Escherichia coli, Shigella dysenteriae and Staphylococcus aureus. The genus Caulerpa also yields antibiotics.

Alginates: Alginic acid is a polymer of carbohydrate. It occurs in the cell wall and middle lamella. They are obtained from Laminaria, Ascophyllum, Fucus, Nereocystis, Turbinaria etc. They are used in pharmaceuticals as emulsifiers and stabilizers as well as for making pills, antibiotic capsules etc. They are also used in the preparation of soups, jellies, cosmetics, toothpastes, polishes, hair dyes, compact powders, lotions, shampoos etc.

Carrageenin: It is a polysaccharide colloid (phycocolloid) obtained from the red algae Chondrus crispus and Gigartina stellata. It is widely used in soups, sauces, milk shakes, cheese, jellies, cream and fruit juices. It is also used in painting and printing.

Agar-agar: It is a non-nitrogenous carbohydrate consisting of two polysaccharides namely agarose and agaropectin. It is obtained from several red algae e.g., Gracilaria, Gelidium, Gigartina and Chondrus etc. It is insoluble in cold water but soluble in hot. It is used as a base for a variety of culture media.

Source of minerals and elements: The members of brown algae called 'kelps' have been the source for obtaining iodine e.g., Laminaria, Macrocystis, Fucus. About 25% of total iodine is extracted from kelps. Similarly red algae like Rhodomela, Polysiphonia and Rhodymenia are sources of bromine.

Sewage disposal : Green unicellular algae such as *Chlorella* and *Chlamydomonas* are used in sewage disposal ponds. They remove CO_2 and restore O_2 by the process of photosynthesis.

Medicines: Sodium lamining sulphate are used as blood anticoagulant and obtained from *Laminaria* and *Durivillea* has antiworm (vermifuge) properties.

Source of protein : The protein of *Chlorella* is superior to cereals as it contains all essential amino acids. Its nutritional value is equal to soybean and spinach.

Harmful aspects

Algal toxicity: Some dinoflagellates like Prymnesium, Gymnodinium are extremely poisonous to fishes. The blue-green alga Microcystis secretes hydroxylamine which not only kills aquatic life but also the birds and cattles who care to drink water. While Lyngbya and Chlorella may cause skin allergies in human beings.

Algal parasitism: The red alga Cephaleuros virescens causes red rust of tea thus destroying the tea leaves. Similar disease are caused by the species of Cephaleuros to coffee plant, Piper and Citrus sp.

Spoilage of drinking water: Forms like Anabaena, Microcystis not only spoil the taste of drinking water but also produces toxic effect. The growth of algae is controlled by using algicides such as dichlorophen, sodium perborate, phygon XI, exalgae, delrad etc.

Water blooms: Algae grow abundantly in water reservoirs where excess of nutrients are available to them. This algal growth floats on the water surface and look like foam or soap lather. It is called water bloom. e.g., Microcystis, Anabaena, Oscillatoria etc.

Some representative algae

Spirogyra

Habitat

Spirogyra was discovered by Link. It is an unbranched filamentous green alga of stagnant fresh waters which forms floating masses (supported by bubbles of oxygen) called **pond scum**. A sheath of mucilage occurs on the outside. It gives a silky touch. Hence Spirogyra is also called **water silk or mermaid's tresses**.

Structure

The thallus is an unbranched and uniseriate filament where cells are arranged in a single row. In some species hold fast is present (e.g., S. fluviatilis). The cells are elongated and cylindrical. The cell wall is two layered the outer is of pectic substance and the inner of cellulose. The outer part (pectin) dissolves in water to form a mucilaginous sheath.

Due to this reason *Spirogyra* filament's are slippery. Transverse or septum can be plane, colligate (with H-shaped piece), replicate (ring like ingrowths) and unduliseptate (undulate). The protoplast is differentiated into plasma membrane, thin layer of cytoplasm, single nucleus, one (e.g. *S.sahni* and *S. venkataramanni*) or many (16 in *S.rectispora*) ribbon (spiral) shaped chloroplasts (wavy margin) with pyrenoids and a large central vacuole. Pyrenoid is made of protein surrounded by starch plate or starch grains and it is the centre of starch formation. Nucleus occurs inside the central vacuole where it is suspended by means of cytoplasmic strands.

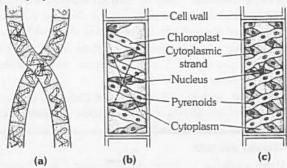

Fig: 1.6-2 Spirogyra (a) Two filaments (b) and (c) Detailed structure of a cell

Reproduction

Spirogyra reproduces by vegetative, asexual and sexual methods.

- (1) **Vegetative reproduction**: It takes place by fragmentation of filament. Later on, each segment gives rise to new plant.
- (2) **Asexual reproduction :** Normally asexual reproduction is absent in *Spirogyra*. It occurs only occasionally by the formation of akinetes, aplanospores and azygospores (Parthenospores).

Akinetes: Under unfavourable conditions, the cells of the filament develop into thick walled structures, which are known as akinetes. On the onset of favourable conditions, these give rise to new plants. Their wall is made up of cellulose and pectin e.g., S. farlowi.

Aplanospores: These nonmotile aplanospores are either round or oval. These later on under favourable condition give rise to the new individuals. Aplanospores are known to occur in *S. aplanospora*, *S. articulate* etc.

Azygospores or Parthenospores : If there is sudden change in the environment, the gametes fail to fuse and each functions as parthenospore.

(3) **Sexual reproduction**: The sexual reproduction in *Spirogyra* is called conjugation, It involves the fusion of two morphologically identical, but physiologically dissimilar gametes.

The conjugation is of two types

(1) **Scalariform conjugation:** This is the most common and advanced type of conjugation. It involves two filaments of *Spirogyra* and takes place between two recently formed cells. The cells of one filament show the formation of **papilla** towards the other filament.

It stimulates the formation of similar papilla in cells lying opposite to them. The two papillae fuse by enzymatic dissolution of the wall thus forming a **conjugation canal**.

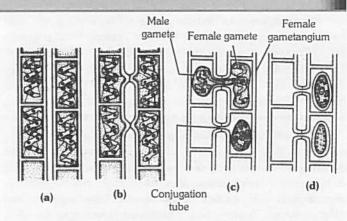

Fig: 1.6-3 (a)-(d) Sexual reproduction showing scalariform conjugation in Spirogyra

The conjugation tube between the two filaments looks like a ladder, through which gamete from one of the gametangia passes through to fuse with the passive gamete of another filament. The gametes are formed singly and both **active** and **passive** gametes are considered male and female gametes respectively. The fusion of both kinds of gametes with each other results into formation of zygospore.

The zygospore wall is differentiated into three layers, the outer **exospore** which is thin, the middle **mesospore** which is a thick layer of cellulose, chitinized and pale yellow to brown in colour, and inner **endospore** which is thin and cellulose in nature.

- (2) Lateral conjugation: It takes place between two nearest cells of the same filament (homothallic). Both male and female gametes are found in same filament. It is of two types.
- (i) Indirect lateral conjugation: Two outgrowths appear on both sides of a transverse septum of two adjacent cells which later on form a conjugation tube. Of the two cells, one behaves as male gametangium from which gamete passes through the tube into female gametangium. By fusion, zygospore is formed. Thus in each second cell of a filament zygospore is formed. It is commonly seen in S. affinis and S. tenuissima.

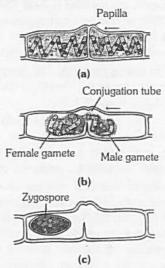

Fig: 1.6-4 Sexual reproduction showing lateral (indirect) conjugation in Spirogyra

(ii) **Direct lateral conjugation**: In this type of conjugation, the male gamete after passing through an aperture in the transverse septum of adjoining gametangium enters the female

gametangium and fuses to form a **zygospore**. The two gametes, though morphologically alike but differ in their behaviour. Hence this type of sexual reproduction corresponds physiologically anisogamy. It is commonly seen in *S. jogensis*.

Germination of zygospores: The zygospores on the arrival of favourable conditions germinate. The nucleus undergoes meiosis to form four haploid nuclei (tetra nucleate). Of these three nuclei degenerate and one functions.

The exo and mesospores rupture and the endospore protudes out in the form of germling. The new cell undergoes transverse division continuously to form a new filament. Thus in the life cycle of Spirogyra, there is no flagellate phase.

Life cycle in Spirogyra is **haplontic** as dominant phase in life cycle is haploid (n) and diploid phase is represented by only zygospore and it undergoes R.D. or meiosis (zygotic meiosis).

Ulothrix

Habitat

It is a green filamentous algae found in slow running fresh water streams. The common species *U. zonata* occurs in cold water whereas *U. flacca* is marine. *U. implexa* occurs in estuaries (where river meets the sea) as **lithophytes**.

Structure

An unbranched filament, consisting of numerous cylindrical or rectangular cells joined end to end. The filaments remain attached to some substratum by means of rhizoidal cell, i.e., showing distinction in base and apex. The basal cell is elongated and colourless known as holdfast while the uppermost cell is rounded.

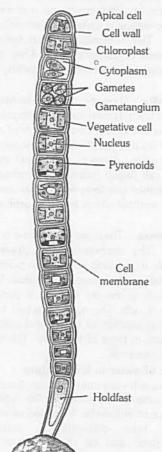

Fig: 1.6-5 A vegetative filament

Cell wall consists of two layers. Inner layer is made up of **cellulose** and outer layer is mostly made up of **protopectin** which is insoluble in water.

Due to presence of protopectin, *Ulothrix* filaments appear as **wet threads**. In the centre of the cell is a nucleus and single **girdle** or **ring** shaped (*U. zonata*) or collar shaped chloroplast. One (*U. rorida*) or more pyrenoids are present in the chloroplast. A vacuole is present, surrounding it is a thin layer of cytoplasm (primordial utricle).

Reproduction

The *Ulothrix* reproduces vegetatively, asexually as well as sexually.

- (1) **Vegetative reproduction**: It takes place by fragmentation. In this process a filament divides into small parts. These smaller fragments grow and give rise to new filaments of *Ulothrix*.
- (2) Asexual reproduction: It takes place by the production of zoospores, aplanospores, hypnospores, akinetes and palmella stage.

Zoospore formation: In favourable conditions, each cell produces zoospores except holdfast. Cytoplasm collects in the centre and divides into 2,4,8,16 or sometimes 32 segments. Each segment develops into biflagellate or quadriflagellate zoospores. Each zoospore is uninucleate, pear-shaped with thin cell membrane (zoospores not having cell wall). The zoospores are of 3 types:

Quadriflagellate macrozoospores: Usually 4 per cell. Quadriflagellate microzoospores: Usually 8 per cell. Biflagellate microzoospores: Usually 16-32 per cell.

The zoospores come out into a vesicle, later on the wall disintegrates (forming a pore in lateral wall) and macro and microzoospores are liberated free and float in water. Microzoospores attach to substrate by their anterior ends while macrozoospores attach by their posterior ends. After sometime zoospores give rise to new individuals.

In *Ulothrix*, aplanospores, hypnospores and akinetes are also formed under unfavourable conditions.

Palmella stage: It is produced in water deficiency or presence of toxic chemicals. A number of small green naked cells are formed in mucilage sheath. These cells can grow and divide. On the approach of favourable condition each cell now change into a quadriflagellate zoospore. Zoospore develop into new plants.

(3) Sexual reproduction: It occurs at the end of growing season. Ulothrix is heterothallic. Sexual reproduction is of isogamous type. The gametes are motile and biflagellate. Except holdfast each cell of the filament can give rise to 64 to 128 gametes.

These gametes are smaller than zoospores. On dehiscence of gametangium, the gametes come out in a bag like structure and float on water.

When two gametes of (+) and (-) strain come together, they fuse and a quadriflagellate zygospore is formed which after floating for sometime on water, rests on the bottom of the pond. At this time, its four flagella disintegrate and a wall is formed surrounding it from all sides. After taking a rest for long period it divides meiotically and gives rise to 4-16 aplanospores or zoospores. These come out of the sac and give rise to a new plant of *Ulothrix*.

Bryophyta

(Gk. Bryon = moss; phyton = plants)

Bryophyta includes the simplest and primitive land plants. Which are characterised by the persence of independent gametophyte and parasitic sporophyte. The term bryophyta was coined by Braun (1864) but bryophytes were delimited in its present form by Schimper (1879). It occupies a position intermediate between algae and pteridophyta. Due to peculiar type of their habitats, they are regarded as 'the amphibians of the plant kingdom'. The science connected with the study of bryophytes called bryology.

Habitats

Bryophytes usually grow in moist and shady places. The plants grow densely together and form green carpets or mats on damp soil, rock, walls, barks of trees and on decaying logs in forests, especially during the rainy season.

Specialized habitats: Some bryophytes grow in diverse habitats such as — aquatic (e.g., Riccia fluitans, Ricciocarpus natans, Riella), epiphytes (e.g., Dendroceros, Radula protensa and many mosses), saprophytes (e.g., Buxbaumia aphylla, Cryptothallus mirabilis), and in dry habitats such as dry heaths (e.g., Polytrichum juniperinum), deserts (e.g., Tortula desertorum) and dry rocks (e.g., Porella platyphylla).

Gametophytic plant body

- (1) The life cycle of bryophytes consists of two distinct phases the gametophytic phase and the sporophytic phase. The haploid gametophyte is dominant, long lived, green and independent whereas the diploid sporophyte is short lived and dependent upon the gametophyte. The two phases are morphologically distinct.
- (2) The plants are small, range from few millimetres (e.g., Zoopsis) to 30–40 centimetres. The tallest species may reach upto 70 cm in length (e.g., Dawsonia).
- (3) The gametophytes are either thalloid (i.e., not differentiated into true roots, true stem and true leaves) or leafy shoot having stem-like central axis and leaf-like appendages.
- (4) The roots are completely absent and they are replaced by unicellular or multicellular thread like rhizoids. In some higher forms the multicellular rhizoids form cords.
- (5) The vascular tissue (i.e., xylem and phloem) are completely absent.

Reproduction

(1) Vegetative reproduction: The bryophytes reproduce vegetatively by following methods:

Death and Decay : Most of these plants reproduce vegetatively by gradual death and decay of the older part of the plant body.

Adventitious branches : Many plants like *Riccia fluitans*, *Reboulia*, *Asterella*, *Pellia* etc. reproduce by adventitious branches. They separate and produce new plants.

Tubers: Several species of *Riccia, Anthoceros, Sewardiella, Asterella* etc. produce tubers which give rise to new plants on the arrival of favourable conditions.

Gemmae : Several members, reproduce vegetatively by forming multicelled gemmae. In *Marchantia*, *Lunularia*, the gemmae are produced in **gemma cups**. Gemmae are also produced on the thallus of *Anthoceros*. Several mosses also produce gemmae on the 'leaves' (*Bryum*), or axis or rhizoids or on the protonema (*Funaria*).

Primary protonema : The mosses generally reproduce vegetatively by breaking of the primary protonema. New gametophores now arise from the buds differentiated on it.

Secondary protonema: In several mossess a secondary protonema may arise from the rhizoids or primary protonema or even from the injured sporophyte. It may produce buds which give rise to new gametophores.

Rhizoids: Mosses may also reproduce vegetatively from the rhizoids e.g., Leucobryum.

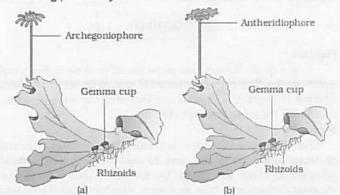

Fig: 1.6-6 Bryophytes (a) Female Thallus (b) Male Thallus

(2) **Sexual reproduction**: It is oogamous, between a flagellate sperm or antherozoid and non motile egg or oosphere. The male sex organs is called as antheridium and the female as archegonium. The antheridial stalk is very distinct whereas the archegonial stalk is generally short. They may be of embedded type e.g., Riccia, Anthoceros or of projecting type e.g., Marchantia, mosses.

Antheridia: They are generally borne on the dorsal surface of the thallus. Each antheridium is distinguishable into a stalk and the body. The antheridial body consists of a mass of androgonial cells covered by a 1-cell thick sterile jacket. The terminal cell of the jacket, when distinct, is called as operculum. Each androgonial cell finally behaves as androcyte mother cell. The androcyte mother cell then forms two androcytes (antherozoid mother cell), each of which is metamorphosed into a biflagellate antherozoid.

Archegonia: These are also borne on the dorsal surface of the thallus. The archegonia are **flask shaped** structures distinguishable into a long neck and a globular, swollen venter. A multicelled stalk is also present in mosses but in others it is very short. The neck is one-cell thick. It is generally made up of six vertical rows of cells. The neck is capped by four cover cells and contain varying number of neck canal cells inside. The venter is also 1-cell thick in most of the plant. The venter contains an egg and a ventral canal cell.

Importance of water in fertilization

The bryophytes are fundamentally terrestrial plants but require presence of water to complete their life cycle. The water is needed for dehiscence of antheridia, liberation of antherozoids, transfer of antherozoids from antheridia to archegonia, opening of archegonial neck, and the movement of antherozoids into the archegonial neck.

Before fertilization the walls of androgonial cells disorganise to form a mucilagenous mass. The opercular cell is removed and the antherozoids are liberated. The neck canal cells and the ventral canal cell also disorganise. The cover cells split apart giving a free passage to incoming antherozoids. The antherozoids are attracted towards the egg by chemotactic stimulus, which in bryophytes, is provided in the form of sugars. Antherozoids enter into archegonia and fertilized the egg.

Sporophyte

- (1) The diploid fertilized egg (zygote) is the first cell of sporophytic generation. It divides and develops into a sporophytic plant body called sporogonium.
- (2) The wall of venter forms calyptra, which provides a protective covering to the developing sporogonium.
- (3) The sporogonium, in most of the cases, is differentiated into foot, seta and capsule.
- (4) The sporogonium is completely dependent on the gametophyte for water and mineral supply and, in most of the cases, partly or wholly for organic nutrition. The sporogonium remains attached to the gametophytic plant body throughout its life.
- (5) The sporogonium is mainly concerned with the production of asexually formed haploid spores (or meiospores). The spores are produced inside the capsule of sporogonia as a result of meiosis in the spore mother cells.
- (6) The spores are the first cells of gametophytic generation. They germinate to produce the gametophytic plant body either directly or through a juvenile filamentous stage, called protonema.

Important features of classes

Campbell (1940), Smith (1955), Takhtajan (1953) divided bryophyta into three classes namely **Hepaticae**, **Anthocerotae** and **Musci**. Proskauer (1957) changed the names of these classes in accordance with the recommendations of the code, into Hepaticopsida, Anthocerotopsida and Bryopsida.

Hepaticopsida: The latin word Hepatica means liver. Thus the members of hepaticopsida are popularly known as **liverworts**.

The gametophytic plant body is small, dorsiventral, thallose or leaf axis (foliose). Chlorophyllous cells contain many chloroplasts, one to several oil bodies, pyrenoids are absent. Rhizoids are unicellular. Sex organs develop from single superficial cells.

Anthocerotopsida: Gametophyte is thalloid. Thalli are lobed, dorsiventral, internally homogenous without any differentiation of tissues. Air chambers and air pores are absent but mucilage cavities may be present. Rhizoids are only smooth walled and scales are absent. Each cell possesses single (some times more) large chloroplast with central pyrenoid and oil bodies are absent. Antheridia are endogenous in origin, borne singly or in groups inside the closed cavities.

Bryopsida: The members of bryopsida are commonly known as **mosses**. Gametophyte is differentiated into two stages – prostrate protonema and erect radial leafy shoot. Leaf-like appendages are spirally arranged on stem like axis. Rhizoids are

multicellular with oblique septa. Sex organs develop from superficial cells.

Economic importance

- (1) **Soil conservation**: Mosses grow in dense mats over the soil surface. They bind the soil particles and prevent soil erosion by running water.
- (2) Formation of soil: Mosses along with lichens play a very important role in the formation of soil over the bare rocky surface. They grow on rocks and add organic matter to the substratum after their death. It makes the rock surface suitable for the growth of higher plants.
- (3) Use in nursery: The Sphagnum plants have magnificent property of retaining water. They can with hold water two hundred times more than their own weight. Hence they are widely used by gardeners to keep cut plant parts moist during transportation and propagation.
- (4) Peat: Sphagnum plants grow as semiaquatic or submerged in acidic marshes. The older portions of plants die but do not decay due to peculiar germicidal properties. Constantly increasing mass of dead remains accumulate year after year. These dead remains are slowly compressed and become hardened due to weight and forms a compact dark coloured peat rich in carbon.
- (5) **Other uses:** Certain bryophytes are used to obtain a number of **antibiotic** substances. Some bryophytes have important medicinal uses. For example The tea prepared from *Polytrichum commune* is used to dissolve kidney and gall bladder stones.

Some representative bryophytes

Funaria (Moss)

Habitat

Funaria is known as **common moss** or **green moss** or **cord moss**. There are 117 species of Funaria which are worldwide or cosmopolitan in distribution. 25 species have been reported from India. Most common species are Funaria hygrometrica, F. obtusa, F. attentua and F. fasicularis.

Funaria grows well in recently burnt grounds rich in plant ashes (alkaline condition). Common places for its growth are moist rocks, moist walls and moist grounds.

External structure (Gametophytic phase): The main plant body of Funaria is gametophyte and is of two forms.

- (1) Juvenile form (creeping protonema).
- (2) Adult form (leafy gametophore).

Protonema is the branched filamentous portion which is produced by germination of spores. It is ephemeral or short lived.

Leaves : These are small, sessile, ovate with acute apex and broad base. Leaves are arranged spirally in 1/3 phyllotaxy in upper region and 3/8 in lower region. A distinct midrib is present.

On the lower portion of the leafy gametophore, there are presence of branched, multicellular rhizoids with oblique septa.

Initially the rhizoids are colourless and hyaline but at maturity they become dark in colour due to dark cell walls. If rhizoids are exposed to light they become green.

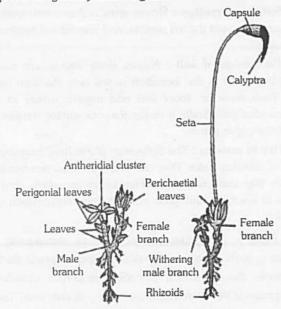

Fig: 1.6-7 Funaria plant showing male and female branches

Reproduction

Funaria reproduces both by vegetative and sexual methods.

(1) **Vegetative reproduction**: Vegetative reproduction takes place by fragmentation, primary protonema, secondary protonema, bulbils, gemma and apospory.

In apospory some cells from any part of sporophyte separate from the parent, fall on the soil and form a protonema. Buds of leafy gametophore are produced on the protonema and give rise to a gametophyte-like plant but the cells have diploid set of chromosome (2n). In this way a gametophyte like plant is produced from diploid sporophyte without reduction division.

(2) **Sexual reproduction**: The *Funaria* plants are monoecious and autoecious, i.e., male (antheridia, club shaped) and female (archegonia, flask shaped) reproductive organs are produced on the same plant but on different branches. Male organs mature first and hence *Funaria* plants are **Protandrous**.

Antheridium: Each male sex organ is reddish brown/orange stalked multicellular club shaped called antheridium. Main branch is male branch which is called antheridiophore. The antheridia are borne at the tip of antheridiophore. The antheridial cluster remains surrounded by a rosette of leaves called Perigonium. In between antheridia are present club shaped green multicelled sterile hair called paraphyses. An antheridium is distinguishable into stalk and the body. It has a 1-cell thick jacket. Jacket is green in the young antheridium but colour changes in mature antheridium. A number of biflagellate sperms are produced by antheridium.

Archegonium: Female receptacle appear bud like. It contains a number of archegonia intermixed with pointed 4-5

celled green paraphyses. The whole complex is surrounded by upwardly bending or convergent perichaetial leaves.

The archegonium of moss is distinguishable into a stalk, venter and a neck. The venter is double layered and contains an egg and a ventral canal cell inside. The neck is several cells high and is made up of six vertical rows of cells. It contains six or more neck canal cells. It is capped by four cover cells or lid cells. At maturity the venter canal cell and neck canal cells degenerate to form mucilaginous mass. It absorbs water and swells up and opens the lid to create a passage upto oosphere. Oosphere secretes sucrose for attracting sperms.

Fertilization : The neck canal cells and the ventral canal cell also degenerate and the cover cells split apart giving a free passage to incoming antherozoid. The fertilization is affected by water medium. Out of many antherozoids, only one of them is able to fuse with the single egg to produce zygote (2n). The zygote without any resting period enlarges and divides to form sporophyte or sporogonium. The first division in zygote is transverse. The epibasal (upper) portion forms capsule and upper half of seta while hypobasal (lower) portion forms foot and lower half of seta.

Sporophytic phase: Fully developed sporophyte or sporogonium is made of three regions, *i.e.*, **basal foot**, **seta and capsule**. Sporophyte is semiparasite on moss plant taking water, minerals and some growth factors.

- (1) Basal foot: Basal foot is embedded in the apex of female branch and is conical in shape. Its function is to absorb nutrients and to provide support for sporophyte.
- (2) Seta: It is a long, slender, reddish brown stalk like structure which bears capsule at the top. Internally it is differentiated into a central cylinder and epidermis. The central cylinder helps in the conduction of water and the thick walled cells of the cortex provide mechanical strength to the slender seta.
- (3) **Capsule**: Capsule is the terminal pear shaped portion. Initially it is surrounded by calyptra but later on this calyptra breaks up. Stomata are present on the lower part of capsule. The capsule consists of three portions, *i.e.*, basal apophysis, central theca and terminal operculum.

Apophysis: Apophysis is green, photosynthetic basal sterile portion of capsule in continuation with seta. In capsule of Funaria primitive types of stomata are present only in apophysis.

Theca: Theca is the fertile middle zone of capsule, situated between apophysis and operculum. The outer layer of theca is epidermis, inner to which is 2 layered hypodermis. Central sterile portion of theca is called columella, outer to which is spore sac containing spores. Spore sac develops from endothecium. It enclose spore mother cells which undergo meiosis to form haploid spores.

Outer to spore sac there are present air spaces transversed by many portions of assimilatory cells called **trabeculae**.

Operculum: The upper region of capsule is slightly oblique having upper cap-like portion called operculum. Which covers the peristome. The opercular region is separated from the theca region by two rings. The lower ring is the rim or diaphragm and the upper is annulus. The peristome is distinguishable into two whorls of radially arranged **peristomial teeth**. In each whorl, there are sixteen teeth. Each tooth is a triangular structure. Outer ring of these teeth called exostome (hygroscopic in nature) and inner ring is called endostome (non-hygroscopic in nature).

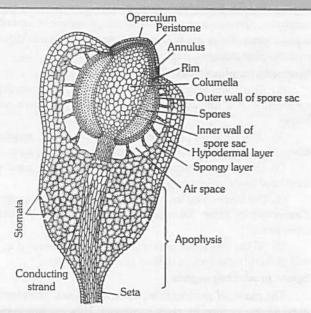

Fig: 1.6-8 L.S. of capsule

Dehiscence of capsule: The capsule swings in air due to twisting movements of long seta. As the capsule matures the thin walled cells including columella dry up. The thin walled cells of operculum break away. The operculum is thus separated along the annulus exposing the peristome. The hygroscopic action of the peristomial teeth also help in the removal of operculum. The capsule becomes inverted due to epinasty. It also shows hygroscopic action. The lengthening and shortening of peristomial teeth help in the dispersal of spores. The inner peristome acts as a sieve allowing only a few spores to escape at a time. Spores have a long viability, i.e., 8-15 years.

Germination of spores: The spore is the first cell of gametophytic generation. Each spore is spherical with two walls, outer one is smooth and coloured called exosporium and inner colourless smooth endosporium. Inside the spore is a single haploid nucleus, numerous chloroplasts and oil globules.

On approach of favourable conditions the spore absorbs water, outer thick exine ruptures and intine comes out in the form of a germ tube which is cut off by means of a septum (oblique). Then it divides and enlarges to form a branched alga like, filamentous, primary protonema.

There are two generations in life cycle of Funaria, i.e., gametophytic generation (n) which is independent and complex and sporophytic generation (2n) which is partially dependent upon gametophytic generation. These two generations follow each other in regular sequence. This is called heteromorphic or heterologous alternation of generations.

Riccia

Habitat

It is a cosmopolitan genus. The plants occur on moist soil or rocks. Most of the species are terrestrial (on damp soils) except *Riccia fluitans*, which is aquatic in nature.

External structure (Gametophytic phase): The main plant body of *Riccia* is gametophytic (n). It is small, green, flat and fleshy. The thallus is dorsiventral and dichotomously branched. The thalli are present in the form of patches called **rosettes**. Scales are found on the margins, while rhizoids are present in the mid-rib

region of thallus. Rhizoids are unicellular and unbranched and are of two types – smooth and tuberculate. Rhizoids help in fixation. In submerged species, (e.g., R. fluitans) scales and rhizoids are not present.

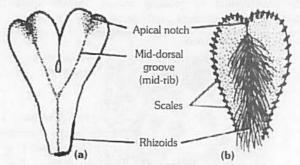

Fig: 1.6-9 Rosette habit (a) Dorsal view of thallus (b) Ventral view of thallus

Internal structure : The thallus is internally differentiated into :

An upper or dorsal photosynthetic region: It consists of vertical rows of chlorenchymatous cells. In between these vertical rows are present very narrow air canals or air chambers. The canals communicate with the outside through air pores. The uppermost cell of each row is enlarged and non-green. These non green cells of vertical rows form a discontinuous and poorly-defined upper epidermis.

A lower or ventral storage region: The lower portion consists of closely packed parenchymatous cells without intercellular spaces. The cells do not contain chloroplasts. They store water and food. The lowermost row of cells form the lower epidermis. Rhizoids and scales develop from the lower epidermis.

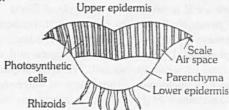

Fig: 1.6-10 A V.T.S of Riccia thallus

Reproduction

Riccia reproduces by both vegetative and sexual method.

- (1) **Vegetative reproduction :** Riccia reproduces vegetatively by progressive death and decay, persistent apices (R. discolor), adventitious branches (R. fluitans), tubers (R. billardieri, R. discolor, R. perennis) and by rhizoid (R. glauca).
- (2) **Sexual reproduction**: Sexual reproduction is oogamous type in *Riccia*. Antheridia and archegonia are the male and female sex organs respectively. Sex organs are embedded in the thallus.

Antheridia produce biflagellated elongated curved sperms, both flagella are alike (whiplash type). Archegonia are flask shaped with neck and venter. Neck enclose 4-6 neck canal cells. Venter wall is single layered and encloses one venter canal cell and one egg cell (oosphere). It attracts sperm by secreting protein and K^+ salts (chemotaxis).

Fertilization : The fertilization is affected by water medium (zooidogamous). Many antherozoids may enter into the archegonium, but only one of them is able to fuse with single egg to form zygote (2n), which is beginning of sporophytic phase.

Sporophytic phase: Sporophyte or sporogonium is also embedded. It is covered by two layered calyptra. Sporogonium is undifferentiated and function like a spore sac on capsule. Nurse cell wall of sporophyte and inner layer of calyptra degenerate to provide nourishment to growing spores. Mature spores are liberated when the surrounding cells decay or dry up.

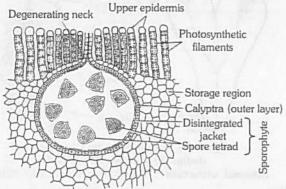

Fig: 1.6-11 V.T.S. of Riccia thallus showing mature sporophyte

Germination of spores: Spores are the first cells of the next gametophytic generation. Spores are dispersed by the decay of the surrounding thallus tissue. The wall of the spore is thick and sculptured, and is differentiated into three layers- the outer exosporium, the middle mesosporium and the inner endosporium which is made of pectose and callose. The surface is having clear triradiate mark. In the mass of cytoplasm, stored food is present in the form of oil – globules. After liberation, the spores germinate in about 6-10 days in presence of light, low temperature and sufficient moisture contents. After absorbing water, the spore swells up. The endosporium grows out in the form of a germ tube which, after further divisions, develops into a new thallus (gametophyte).

Thus there are 2 generations in life cycle of *Riccia*. The main plant body is gametophytic (n). The gametophytic phase starts with formation of spores and ends with fertilization. The second phase is sporophytic phase (2n), which starts with zygote and ends with reduction division of spore mother cell. The sporophytic phase is dependent upon gametophyte. Thus there is heteromorphic or heterologous alternation of generations in *Riccia*. So life cycle in *Riccia* is diplohaplontic.

Pteridophyta

(Gk. Pteron = father/fern; phyton = plants)

The term pteridophyta was first introduced by Haeckel in (1866). The pteridophytes are flowerless, seedless, spore producing vascular plant which have successfully invaded the land. Pteridophytes represent an intermediate position between bryophytes and spermatophytes (Gymnosperm and Angiosperm). They are also called vascular cryptogams. (The term cryptogams was coined by Linnaeus (1737) which means plants without seeds). The group has a long fossil history. Pteridophytes flourished well during devonian, missipian and pensylvanian periods of late paleozoic age. This period can be well recognised as "age of pteridophyta".

Habitat

The plants of pteridophytes are mostly terrestrial. They prefer shady habitats. Some species of Selaginella and Adiantum are xerophytes. A fern, Acrostichum aureum is a halophyte. Some species e.g., Selaginella oregana, Psilotum flacidum, Lycopodium squarrosum and ferns like Asplenium nidus, Pleopeltis sp. are

epiphytes. Marsilea occurs as a terrestrial, amphibious as well as an aquatic plant. There are true aquatic ferns like Salvinia (Salvinia is root less pteridophyte), Azolla and Ceratopteris.

Sporophytic plant body

- (1) The main independent plant body of pteridophytes is sporophyte. It is differentiated into true roots, true stem and true leaves.
- (2) The primary root is short lived. It is replaced by adventitious roots. The root has a permanent growing apex.
- (3) The stems are usually herbaceous (except in some woody ferns) and branched monopodially or dichotomously.
- (4) The leaves may be small microphyllous (e.g., Lycopodium, Equisetum) or large macrophyllous (e.g., Pteridium, Pteris and other ferns).
- (5) All the vegetative parts possess vascular tissues (i.e., xylem and phloem) organized in definite groups or steles.

Spore producing organs

The plants of pteridophytes are sporophytes. They reproduce asexually by forming spores in sporangia. They are **homosporous** but a few plants are **heterosporous** also e.g., Isoetes, Selaginella, Marsilea, Regnellidium, Pilularia, Azolla and Salvinia. In Selaginella the sporangia are borne in relation to sporophylls which constitute a strobilus. In Equisetum they are borne on sporangiophores which constitute a cone. In ferns the sporangia are borne in **sori** on the sporophylls. The sori are of three types:

- (1) **Simple sorus**: Here all the sporangia mature at the same time.
- (2) Gradate sorus: Here the oldest sporangium lies in the centre and the sporangia on either side show successively younger stages.
- (3) Mixed sorus: It shows mixed arrangement of younger and older sporangia.

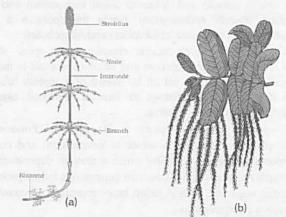

Fig: 1.6-12 Pteridophytes (a) Equisetum (b) Salvinia

Sporangium

The sporangia are generally stalked structures. Each sporangium is distinguishable into a jacket enclosing a mass of sporogenous tissue. The sporangial jacket may be 2-4 layered. The innermost wall layer is the tapetum. No tapetum is formed in *Psilotum* and *Tmesipteris*. It is a nutritive layer which degenerates at maturity of the sporangium. The sporangial jacket in some ferns shows distinctions of annulus and stomium. On the basis of development, the sporangia have been classified by Goebel, 1881 into two categories as under:

- (1) **Eusporangiate type:** Such a sporangium develops from a group of superficial initials. They divide periclinally into outer and inner components. The outer cells form the wall whereas the inner cells give rise to sporogenous tissue. *e.g.*, *Selaginella*, *Equisetum*, *Lycopodium*.
- (2) **Leptosporangiate type**: Such a sporangium arises from a single superficial initial. It divides periclinally into outer and inner components. While the inner cell forms the stalk, the outer gives rise to sporagnium proper. In *Marattia alata*, the sporangia in a sorus may fuse to form a synangium. e.g., Salvinia, Azolla.

Spore

The plants may be homosporous, i.e., produce only one type of spores (e.g., Lycopodium, Pteridium) or heterosporous i.e., produce two different types of spores, smaller microspores and larger – megaspores (e.g., Selaginella, Marsilea etc.). The spore germination is homosporous pteridophytes may be bipolar (e.g., Lycopodium, Equisetum) or tripolar (e.g., Hymenophyllum) or amorphous (e.g., Angiopteris).

Sex organs and Fertilization

The archegonia and antheridia are generally of embedded type. The archegonium consists of neck which usually projects from the surface of the prothallus. It contains 1-2 neck canal cells. There is no venter. The egg and the venter canal cell remain surrounded by the cells of prothallus. The antheridia are generally sessile. They have a 1-cell thick jacket enclosing a mass of androgonial cells. They form the androcytes which are metamorphosed into biflagellate (*Lycopodium*, *Selaginella*) or multiflagellate (*Equisetum*, *ferns*) antherozoids.

Fertilization is affected by water medium (**zooidogamous**). The antherozoids are attracted towards the egg by a chemotactic stimulus provided by the degeneration of neck canal cell and venter canal cell, in the form of malic acid.

Embryogeny

As a result of fertilization the zygote is formed. It divides into an upper or anterior **epibasal cell** and a lower or posterior **hypobasal cell**.

In Selaginella, Lycopodium the epibasal cell forms the suspensor and the hypobasal gives rise to embryo proper. By further segmentation a quadrant and then an octant is formed. Usually the epibasal quadrant forms the stem and root and the hypobasal gives rise to foot and root.

The young sporophyte of pteridophytes is dependent upon the gametophyte for food which is drawn with the help of its foot. Like bryophytes, the pteridophytes also show heteromorphic alternation of generations.

Stelar system

The **stelar theory** was proposed by Van Tiegham and Douliot (1886). Some important types of steles found in pteridophytes are:

(1) Protostele: Solid core of xylem surrounded by phloem, pericycle and endodermis. The types of protosteles are:

Haplostele: A protostele having a central smooth core of xylem surrounded by phloem, pericycle and endodermis e.g., Selaginella sp., Lygodium, etc.

Actinostele: A protostele having star-shaped xylem core with radiating ribs e.g., *Psilotum*, *Lycopodium serratum*, etc.

Plectostele: A protostele having xylem broken into parallel plates alternating with parallel phloem plates e.g., Lycopodium clavatum.

Mixed protostele: A protostele having several xylem groups scattered and embedded in phloem e.g., Lycopodium cernuum.

(2) Siphonostele: A stele having central pith. It is formed by medullation (or appearance of pith) in the protostele. The types of siphonosteles are:

Ectophloic siphonostele: The central pith is surrounded by xylem, phloem, pericycle and endodermis. The phloem occurs only outside the xylem e.g., Osmunda.

Amphiphloic siphonostele: The ring of xylem is surrounded on both outer and inner sides by phloem, pericycle and endodermis e.g., Marsilea rhizome, Adiantum pedatum rhizome.

Modification of siphonostele

- (1) Cladosiphonic siphonostele: A siphonostele not perforated by leaf gaps e.g., a few species of Selaginella.
- (2) **Phyllosiphonic siphonostele :** A siphonostele perforated by leaf gaps *e.g.*, *Nephrolepis*.
- (3) Solenostele: A siphonostele perforated by leaf gaps which are scattered but not overlapping e.g., Ferns.
- (4) Dictyostele: A siphonostele perforated by several overlapping leaf gaps. Each separate strand is called meristele. e.g., Dryopteris, Pteridium, Pteris, etc.
- (5) Polycyclic dictyostele: A dictyostele consisting of two or more concentric rings of meristeles e.g., Pteridium aquilinum.
- (6) **Eustele :** Much dissected siphonostele having vascular strands separated apart by parenchyma *e.g.*, *Equisetum*.

Heterospory

The sporophytes reproduce asexually producing spores in sporangia. When all the spores are alike *i.e.*, almost of the same size, the phenomenon is called homospory. However, in some pteridophytes, two types of spores are formed which differ significantly in their size as also in function. This phenomenon is called as heterospory. It is seen in pteridophytes like *Selaginella*, *Isoetes*, *Stylites*, *Marsilea*, *Regnellidium*, *Pilularia*, *Azolla*, *Salvinia* and *Platyzoma*.

Apogamy, Apospory and Parthenogenesis

The terms **apogamy** was coined by de Bary (1878). It is defined as formation of sporophyte from a gametophytic cell other than egg without fertilization. It was first observed by Farlow (1874) in *Pteris cretica*. Thereafter it was observed in several other plants e.g., Lycopodium, Selaginella, Nephrodium, Lastrea, Marsilea etc. The apogamy is of two types, **obligate** and **facultative**.

The formation of gametophyte from a sporophytic cell without meiosis is called as **apospory**. This phenomenon was first observed by Druery (1884) in *Athyrium filix-femina*. Thereafter it has been established in several pteridophytes. *e.g.*, *Pteridium aquilinum*, *Asplenium*, *Trichomanes* etc. Induced apospory was seen in *Pteris* species.

Formation of sporophyte from egg without fertilization is called as parthenogenesis. Farmer and Digby (1907) observed that in homosporous, leptosporangiate ferns, apospory was always followed by parthenogenesis. This phenomenon has been observed in several species of Selaginella and Marsilea.

Economic importance

- (1) **Ornamental value :** Many ferns are grown as ornamental plants in gardens for their large and graceful foliage. e.g., species of Lycopodium, Nephrolepis, Selaginella, Lygodium, Anemia, Cyathea etc.
- (2) **Medicines**: An anthelmintic drug is obtained from the rhizomes and petioles of the fern *Dryopteris*. *Lycopodium clavatum* is used in skin diseases. *Equisetum arvense* has diuretic properties.
- (3) **Food**: The sporocarps of *Marsilea* are rich source of starch and used by tribals for their nutritive value.
- (4) Soil conservation: Plants like Selaginella are useful in soil conservation.

Some representative pteridophytes

Selaginella

Habitat

Selaginella is commonly called the little club moss or spike moss. Selaginella is mainly found in damp shaded places. A few species are xerophytic and can withstand the dry conditions for months together. In dry conditions, the plant rolls up into a

compact ball and root system is disorganized. During the rainy conditions the ball on absorbing moisture, becomes green again. Such plants are called **resurrection plants** or **bird's nest moss**, e.g., S.lepidophylla and S. pilifera are xerophytes and sold in the market as novelties, S.bryopteris (Sanjeevani) and S.rupestris (ornamental).

The common epiphytic species are S. chrysocaulos, S. kraussiana, S. oregana, S. chrysorrhizos.

Structure

External structure: The plant body is sporophytic (2n), which is an evergreen and delicate herb having adventitious roots. The plants show great variation in their morphology. Some species are prostrate growing upon the surface (e.g., S.kraussiana), some are suberect (e.g., S.trachyphylla) and others are climbers (e.g., S.allegans). The stem is covered with four rows of small leaves, out of these two rows are of smaller leaves and two of large leaves species with dimorphic leaves such as S.kraussiana, S.helvetica, S.lepidophylla, S.chrysocaulos etc.

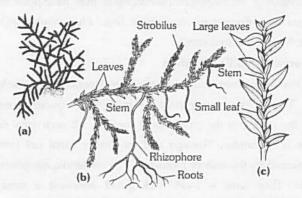

Fig: 1.6-13 Selaginella kraussiana: (a) General habit (b) A part of the plant (c) Small portion of plant showing arrangement of leaves

Leaves are sessile, ovate or lanceolate with acute apex. Unbranched midrib is present in the centre of each leaf. The leaves are ligulate, i.e., a flap-like outgrowth is present at the base on adaxial side called ligule. It may be fan-shaped or tongue-shaped or lobed or fringed. At the base of ligule, there is present a sheath of elongated cells called glossopodium (secretory).

The leaves possess a midrib but there is **no venation**. At the place of bifurcation of stem, a leafless, colourless, positively geotropic, elongated, cylindrical structure grows downwards. This is called the rhizophore and is quite different from the root in that it has no root cap.

Internal structure

Root: In root the stele is a protostele. It has a central core of xylem surrounded by phloem which is **horse shoe shaped**. It has a single protoxylem element (monarch). The xylem is exarch.

Stem : The stem is internally distinguishable into a single layered epidermis having no stomata. This is followed by cortex. The stele is suspended by unicelled (rarely multicelled) trabaculae (modified endodermal cell).

This layer, due to presence of casparian strips is regarded as endodermis. The stele is a protostele (haplostele) surrounded by a pericycle with a central core of xylem enclosed by phloem. Protostele is **diarch** and **exarch**. Stem of Selaginella kraussiana shows distelic condition. More than one steles are present in the stem of some pteridophytes (i.e., polystelic condition) e.g., steles are present in S. laevigata.

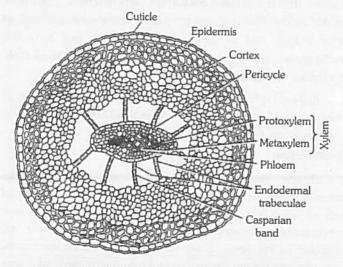

Fig. 1.6-14 T.S. stem of Selaginella

Leaf: The leaf displays a simple structure. The mesophyll is uniform, being composed of elongated chlorenchymatous cells with large intercellular spaces. Each measophyll cells has one (S.martensii), two (S.kraussiana) or eight (S.willdenovii) chloroplasts. Each chloroplast has several pyrenoid-like bodies similar to Anthocerotales. The single midrib bundle is concentric, amphicribal (ectophloic) with annular or spiral tracheids surrounded by a few sieve elements.

Rhizophore: Its anatomy is similar to root. The stele is a protostele. The xylem is exarch and monarch with several protoxylem groups. In *S.kraussiana*, centroxylic condition (having protoxylem in the centre surrounded by metaxylem elements) has been recorded.

Reproduction

Reproduction takes place by vegetative and sexual (by spores) method.

(1) **Vegetative reproduction**: It is of rare occurrence and may takes place by following methods:

Fragmentation: It occurs during very humid conditions. Some branches act as adventitious branches, which get separated from the plant and give rise to new *Selaginella* plants, *e.g.*, in *S.rupestris*.

By resting buds : In some cases, terminal leaves get overlapped and become fleshy and form resting buds, which are means of vegetative reproduction, *e.g.*, in *S.chrysocaulos*.

By tubers: In S.chrysorrhizos, some branches penetrate into substratum and at terminal ends swell to form tubers, which give rise to new plants.

By apogamy: In some cases, development of sporophyte occurs directly from gametophyte without intervention of sex organs, it is called apogamy and such plants are genetically haploid.

(2) **Sexual reproduction**: The reproductive structure in *Selaginella* is strobilus or spike. It is a sessile structure and develops at the terminal ends of the branches and its length varies from 1/4th of an inch to 2–3 inches in different species.

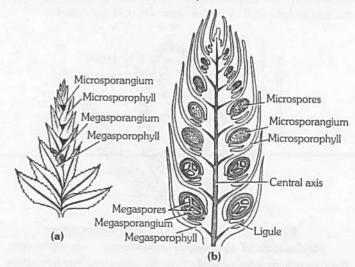

Fig: 1.6-15 Selaginella: (a) A strobilus showing compactly arranged sporophylls (b) L.S. through strobilus

A strobilus is having many ligulate sporophylls arranged in cluster, each bearing a small, short, stalked sporangium on its upper surface. The sporangia are of two types :

(i) **Megasporangia**: Borne on megasporophylls. Megasporangium is pale greenish and contains chalky white, yellow or orange **megaspores**.

The megasporangium **is four-lobed** structure with a 2-layered jacket, one layer of tapetum and a large number of microspore mother cell. However, only one megaspore mother cell is functional. After meiosis it produces 4 megaspores out of which 1–3 may degenerate. In *S. rupestris*, there is only a single megaspore.

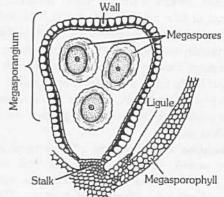

Fig: 1.6-16 Selaginella: V.S. of megasporangium

 (ii) Microsporangia: Borne on microsporophylls having a large number of small spores. Thus Selaginella is heterosporous.
 Microsporangium is pale yellow, oval or spherical body, with 2-

layered jacket, one layered tapetum and a number of microspore mother cells which undergo meiosis and form haploid microspores. The main body consists of a wall having two layers, inside which are present numerous small microspores (400–2000). Development of sporangium is of eusporangiate type.

In most of the cases, the strobilus or spike bears two types of sporophylls; the lower are megasporophylls and the upper ones are microsporophylls. In *S.kraussiana* there is single megasporophyll at the base of spike and the rest of upper are microsporophylls.

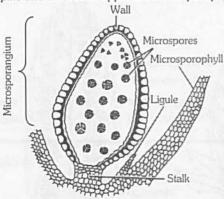

Fig: 1.6-17 Selaginella: V.S. of microsporangium

Mechanism of sporangial dehiscence: On maturation, the sporangium splits vertically from the upper end into two valves (vertical apical splitting). The lower cup-shaped portion shrinks and the spores come out through apical slits. This is brought about by cohesion owing to hygroscopic changes in the apical and lateral part of the sporangial wall. This liberation of spores takes place at intervals in small masses.

Germination of microspore: The microspore is a double layered structure and contains oil droplets. The outer wall exospore is much thicker (spiny) than inner endospore. It measures $15{\text -}50\mu$ in diameter. The microspore on germination forms the male gametophyte. The structure and development of male gametophyte was first described by Slagg (1932). The first division leads to formation of a small prothallial cell and a large antheridial cell.

The larger antheridial cell, by further divisions, gives rise to central group of four primary androgonial cells, surrounded by eight jacket cells. At this 13-celled stage (1 prothallial + 8 jacket cells and 4 primary androgonial cells), the microspore is shed from microsporangium. Each of the central groups of cells divides and redivides and finally forms about 256 spirally coiled antherozoids with two flagella (biflagellated); the jacket cells disintegrate. It takes about three weeks for germination of microspore and formation of antherozoids or sperms.

Germination of megaspore: The megaspore has three wall layers namely exospore, mesospore and endospore. It measures 1.5-5.0~mm in diameter. The megaspore on germination forms the female gametophyte. Generally the megaspore germinates inside the megasporangium (i.e., in situ). In some sps., megaspores are shed after the development of first archegonium, i.e., in S.kraussiana, while in S.apoda and S.rupestris, megaspores are not liberated till a well developed embryo is formed.

During the development of female gametophyte, the protoplasm after contraction forms a small sac-like structure. The outer wall bursts into two layers, the exospore and mesospore. At this stage, megaspore contains a haploid nucleus which by division produces many nuclei. Wall formation takes place in the upper beak-like portion and a small-celled cellular tissue is formed. This is one celled thick at the sides and three celled thick in the middle. This is female prothallus. Some superficial cells at apex enlarge and act as archegonial initials and form the archegonia. The megaspore bursts exposing the female prothallus. Vestigial rhizoids develop.

Archegonium are sessile and embedded type and consists of very short neck having a single neck canal cell and a venter, having a single ventral canal cell and an egg.

Fertilization

Usually the male gametophytes are shed from the microsporangium on the ground at 13-celled stage (one prothallial cell +8 jacket cells +4 androgonial cell). Here they complete their development ultimately producing spermatozoids. These are liberated by the decay of the microspore wall. If the microspore falls near the mature female gametophyte, the sperms swim from the male gametophyte to reach archegonia and one sperm fuses with egg to form zygote. Water is necessary for fertilization and sperms are attracted due to **malic acid**.

Development of embryo or Sporophyte

The oosphere after fertilization gets surrounded by wall and become oospore. The oospore (zygote) divides transversely into two cells, the upper epibasal cell which forms suspensor cell and the hypobasal cell which develops into embryo.

The embryo differentiates into foot, root, primary stem with two rudimentary leaves and rhizophore. By growth of stem and the root, the young sporophyte becomes independent of the gametophyte tissue and falls on the ground where the primary rhizophore forms roots that grow into the soil and the plant starts independent life.

In some species of *Selaginella*, the archegonial initial develop apogamously into embryo. In *S.intermedia*, no microspores are formed. Here the embryo develops parthenogenetically from the egg. In *S.helvetica*, the archegonia fails to open and here also parthenogenetic development of embryo is seen.

There is distinct **heteromorphic** alternation of generations in *Selaginella*.

Pteris, Dryopteris and Pteridium (Fern)

Habitat

Ferns live in moist, cool and shady places. They are perennial and evergreen. Fern Dryopteris filix-mas is commonly known as **Beech fern** or Male shield fern or **Hay scented fern**. There are about 150 sps. and 25 sps. have been reported in India. It is found in sub-tropical regions as well as warm temperate regions.

Structure

Fern plant is sporophytic (2n) with an underground rhizomatous stem, large aerial leaves or fronds and adventitious roots. Rhizome is sparingly branched in *Dryopteris*, moderately branched in *Pteris* and *Adiantum* (*Adiantum* is commonly called "Maiden hair fern" or walking fern because it propagates vegetatively by its leaf tips) and profusely branched in *Pteridium*. The younger leaf is called like a spring from apex downwards are called circinate venation. The venation (arrangement of viens) in leaf is open furcate type.

Younger parts of leaves and rhizome are surrounded by brown hairy structures called **scales** or ramenta. Leaf bases are persistent

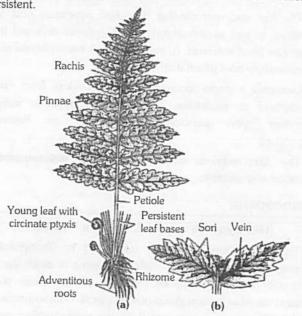

Fig: 1.6-18 Dryopteris (a) Plant showing habit

Root: In root the xylem is diarch and exarch with two phloem groups alternating the protoxylem.

Rhizome: Meristeles are found in fern rhizomes. Each meristele has its own endodermis followed by thin walled pericycle. It is amphicribal with mesarch xylem. The phloem lacks companion cells. In *Dryopteris filix-mas* the vasculature comprises a dictyostele consisting of a ring of meristele. In *Pteris*, however, the vasculature ranges from solenostele to polycyclic dictyostele.

Rachis: In the rachis of *Dryopteris filix-mas* there are 6–8 meristeles arragned in a horse-shoe like manner and single arched with hooked xylem in *Pteris*. The structure of the meristele is similar to that of rhizome.

Leaf lamina : Transverse section of lamina exhibits cuticularised upper and lower epidermis having chloroplast. The vascular strands lie embedded in mesophyll. Each strand is generally amphicribal but sometimes they are bicollateral also. The bundles in minor veins are collateral.

Reproduction

Vegetative reproduction : Vegetative reproduction can occur through fragmentation or rhizome and adventitious buds and these on separation gives rise to new fern plant.

Sexual reproduction: Sexual reproduction takes place through spores. Spores are born in sporangia. The spores are of one kind only (homosporous). When leaves are mature they bear groups of sori on the under surface of fertile pinnae. Such fronds are called sporophylls.

Sori are linear and submarginal in Pteris and Pteridium and median abaxial in Dryopteris. Each sorus is surrounded by a kidney-shaped covering called indusium. In Dryopteris, true

indusium is present because this arises from placenta or placental tissue, from which sporangia arise. (In *Pteris* false indusium is there because it is formed by leaf margins).

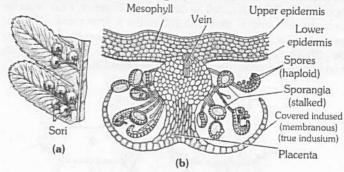

Fig: 1.6-19 *Dryopteris* (a) Part of sporophyll with sori (b) T.S. of sorus

In sorus of Pteridium is covered by two flap like appendages that protect the sporangia. The upper flap is called false indusium and lower is called the true indusium. In the centre of sorus, the vein ends into placental tissue from where arise a number of sporangia. The sorus is mixed in *Dryopteris* (i.e., no definite arrangement of sporangia).

Sporangium: The sporangial development is leptosporangiate *i.e.*, it develops from a single superficial initial. (In eusporangiate type the sporangium arises from a group of initials). A sporangium is distinguishable into a stalk and a capsule. The stalk is multicelled and biseriate.

The capsule is oval or elliptical and biconvex in shape. It consists of a single layered wall followed by double layered tapetum that encloses the archesporium. The archesporial cells divide and redivide to form a mass of sporogenous tissue. Most of the sporogenous cells behave as spore mother cells. They undergo meiosis to form tetrahedral tetrads of (haploid) spores. As a result 32–64 spores are formed in each capsule. The tapetal layer is nutritive. It degenerates at maturity of the sporangium.

Gametophytic generation

Spores: It is the first cell of gametophytic generation. Spores are double layered. The outer wall **exospore** is much thicker than inner **endospore**. On approach of favourable condition spore germinates to form a filamentous gametophyte which develops into green, dorsiventral and heart shaped prothallus.

Prothallus : Fern prothallus is monoecious but protandrous (antheridia mature first). Antheridia are present in between the rhizoids while archegonia are present near the apical notch.

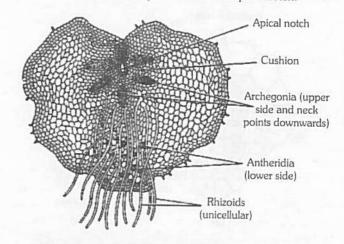

Fig: 1.6-20 Mature prothallus of Dryopteris

Antheridium: It consists of a three celled jacket enclosing a mass of androgonial cells. The two lower jacket cells are ring like (first and second ring cells), and the terminal cell is called as opercular cell or cover cell or cap cell. Sometimes, there may be two cap cells and in that case the jacket is four celled. The last generation of androgonial cells forms the androcytes. There may be 20–25 androcytes in an antheridium, each of which metamorphose into a spirally coiled, multiflagellate antherozoid.

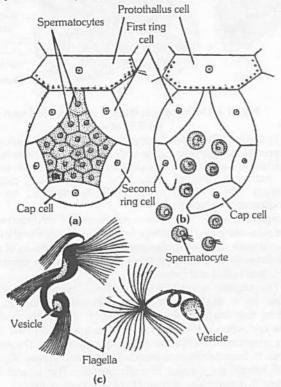

Fig: 1.6-21 Dryopteris (a) L.S. antheridium (b) dehisced antheridium (c) Multiflagellate spermatozoids

Archegonium: It is a flask-shaped structure having venter and neck. Neck is projected out of the prothallus and is curved posteriorly.

Venter is having basal large egg cell and upper small venter canal cell. The neck is having single neck canal cell but is binucleate. Venter is not having any covering or jacket but neck is surrounded by jacket of 4 vertical rows of cells.

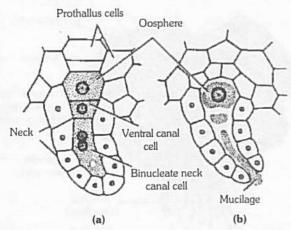

Fig: 1.6-22 Dryopteris (a) Mature archegonium (b) Before fertilization

Fertilization and development of sporophyte: Fertilization takes place in the presence of water. The antherozoids are attracted towards archegonium due to the presence of malic acid in the mucilage oozing out from archegonia.

A single antherozoid is able to fuse with egg to form zygote (2n), which is beginning of sporophytic generation.

Zygote divides first by vertical division, followed by another vertical division and quadrate stage is formed. Then octant stage is formed by transverse division.

The foot and root develop from four hypobasal cells and cotyledons as well as stem develop from epibasal cells and thus sporophytic plant is formed. At maturity foot is hemispherical mass of gametophyte from which it absorbs food.

Generally a single sporophytic plant develops from single gametophyte or prothallus. The fern sporophyte is initially dependent upon gametophyte but later on becomes independent.

The life cycle is diplohaplontic with **heteromorphic** alternation of generation.

Gymnosperm

(Gk. Gymnos = naked; sperma = seed)

The term gymnosperm was introduced by Theophrastus. Gymnosperm (Gk. Gymnos = naked; sperma = seed) are the plants with exposed or naked seeds or ovules. These plants represent the most ancient group of seed plants. Gymnosperms are called fruitless phanerogames or flowering plants without ovary. Robert Brown (1827) separated them from angiosperms and placed under a distinct group due to presence of unprotected ovules in them. The gymnosperms originated much earlier then angiosperms. However, most of the members of this group have now become extinct and only few living forms are known today.

Distribution

Plants of gymnosperms occur throughout the world. The group is presently represented by only 900 living species. Of these, about 500 species belong to 'Conifers' or cone bearing plants. Several species of conifer occur in north-west America and eastern and central China. In India several members are found in Himalayas, *Podocarpus* and *Cupressus* in the central and *Larix*, *Tsuga*, *Cephalotaxus* in the eastern.

Habit

Living gymnosperms are mostly perennials, xerophytic, evergreen, arboreal and woody plants. They grow as woody trees, bushy shrubs or rarely as climbers (e.g., Gnetales). None of them are herbs or annuals.

External features

- (1) The plant body is sporophyte and differentiated into root, stem and leaves.
- (2) The plant possess well developed tap root system. In some cases the roots are symbiotically associated with algae (e.g., Coralloid roots of Cycas) or with fungi (e.g., Mycorrhizal roots of Pinus).

- (3) The stem is erect, aerial, solid, woody and branched (unbranched in Cycadales) but almost tuberous in Zamia.
 - (4) The leaves may be microphyllous or megaphyllous.
- (5) In gymnosperm xylem is generally made up of tracheids but vessels have been observed in Gnetum, Ephedra and Welwitschia.
- (6) The primitive haplochelic type of stomata are found in Cycas, Pinus, Ginkgo, Ephedra etc.
 - (7) Development of oospore is meroblastic.

Gymnospermous wood

Monoxylic wood: The wood formed may be in one ring due to persistent cambium. Such a wood is called as monoxylic e.g., Pinus.

Cambial activity is short lived, cortex and pith are broad, parenchymatous rays are broad, wood is soft and commercially useless. e.g., Cycas.

Pycnoxylic wood: The wood is formed in more than one ring due to ephimeral nature of cambium. Such a wood is called as polyxylic.

Cambial activity is long lived, cortex and pith are reduced, parenchymatous rays are few, wood is hard and compact, wood is commercially most important and used as good quality timber. e.g., Pinus.

Reproduction

Gymnosperms are heterosporous, i.e., produce two different kinds of spores – the male microspores and the female megaspores. The spores are borne inside the sporangia. The two types of sporangia are borne on special leaf-like structures, called sporophylls. The microsporangia (pollen sacs) are borne on microsporophylls (= stamens) and the megasporangia (ovules) are borne on megasporophylls (= carpels).

The sporophylls are usually aggregated in the form of compact structures called cones or strobili. The cones are generally unisexual, i.e., the male cones are microsporangiate (pollen cones) and the female cones are megasporangiate (seed cones). The male cones are short lived whereas the female cones are long lived. The female cones remain attached on the plants for several years till the maturity or ripening of the seeds.

Pollination

The microsporangium (Pollen sac) produces numerous light pollen grains. Pollination is anemophilous (wind pollination). The ovules are orthotropous and remain exposed on the megasporophyll. Each ovule is surrounded by integuments. It encloses the nucellus and a female gametophyte formed from the haploid megaspore. The female gametophyte contains archegonia. The pollen grains are captured by the pollination drop secreted by the micropyle of the ovule. When it dries, the grains are sucked in the pollen chamber. The pollen grains now germinate. A pollen tube is formed due to elongation of the tube cell. In Cycas and Ginkgo the pollen tube is haustorial in nature. The lower end of the tube bursts and releases the male gametes which fuse with the egg to form the zygote.

Fertilization

Fertilization occurs by siphonogamy, i.e., the male gametes are carried to the archegonia through pollen tube (except in Cycas where pollen tube functions as haustorium and fertilization occurs by zoodiogamy). Fertilization thus takes place in the absence of external water.

Embryogeny

The zygote undergoes free-nuclear divisions in *Cycas* followed by wall formation. There are no free-nuclear divisions in *Sequoia* and *Gnetum*. The embryo is soon differentiated into an upper haustorial, middle suspensor and lower embryonal regions. In *Pinus*, on the other hand, the zygote gets differentiated into four tiers of four cells each, designated as open tier, rosette tier, suspensor tier and embryonal tier. Cleavage polyembryony is seen in *Pinus*. The embryonal part shows differentiation of radicle, hypocotyl, cotyledons and plumule.

Seed

As a result of fertilization the ovule develops into a seed. The integument forms the seed coat. The middle stony layer of the integument forms the **testa** whereas the inner fleshy layer gives rise to tegmen. The nucellus persists as a cap like **perisperm**. In *Taxus* a fleshy **aril** is also present at the base as a cup like structure. The seeds of gymnosperms comprise tissue of three generations namely **parent sporophytic** (integument and nucellus), **gametophytic** (endosperm) and **second sporophytic** (embryo).

Living fossils

When a group of plants is represented by a single genus or species while rest of the other representatives of the group have become extinct and fossilized the long surviving individual is called a living fossil e.g., Ginkgo biloba. However, Cycas is also regarded as a living fossil because most of the cycad species are confined to tropical and subtropical regions and the group is becoming endangered. Therefore, cycads have been referred as reptiles of plant kingdom or panda of vegetable kingdom.

Economic importance

- (1) **Ornamentals:** Some of the gymnosperms are grown in the gardens in different parts of the world e.g., Cycas revoluta, Ginkgo biloba, Araucaria cookii, A. bidwilli, Biota orientalis, Cupressus sp., Juniperus sp., Thuja sp., Taxus baccata, Cryptomeria japonica etc.
- (2) **Wood**: Several plants of this group yield useful timber. The wood of *Cedrus deodara* is used for making railway sleepers. It is also used as a structural timber and making bridges. The wood of *Callitris verrucosa*, *Pinus roxburghii*, *P. wallichiana*, *P. pinaster*, *P. lambertiana* etc. is used for making furniture. *Juniperus virginiana* wood is used for making pencils. The gymnosperm *Agathis australis* is perhaps the largest timber producing tree of the world. Soft wood of many gymnosperms is used for making toys.
- (3) Resins: Several conifers yield resin which is obtained by tapping. By distilling the oleoresin is obtained from pines.

The resins are of three types namely hard resins, oleoresins and gum-resins. Several hard resins are obtained from living and fossil conifers which are as under:

Copals: Kauri copal is obtained from Agathis australis and manila copal from Agathis alba.

Amber : It is obtained from the fossil conifer *Pinites* succinifera.

Canada balsam: It is obtained from Abies balsamea.

Spruce gum: It is obtained from Picea rubens.

Bordeaux turpentine: It is obtained from *Pinus pinaster*. **Venetian turpentine**: It is obtained from *Larix decidua*.

- (4) **Essential oils**: They are obtained from several plants. These oils are used mainly in perfumery, soap industry etc. The important oil yielding plants are *Tsuga canadensis*, *Picea glauca*, *Abies siberica* and *Cedrus deodara*.
- (5) **Paper industry**: The wood of several gymnosperms, particularly those of conifers is used in paper industry e.g., Abies pindrow, Picea smithiana, Cryptomeria japonica, Pinus roxburghii, Tsuga canadensis etc.
- (6) **Edible**: The seeds of *Pinus gerardiana* (chilgoza) and *P. roxburghii* are edible. Sago is obtained from *Cycas revoluta* and *Cycas circinalis*. The seeds of *Cycas* sp. are used in the preparation of many edible products.
- (7) **Medicinal use**: Species of *Ephedra* yield an alkaloid called ephedrine. It is used in the preparation of medicines for the treatment of cough, asthma and bronchitis.

Some representative gymnosperms

Pinus

Habitat

It is commonly known as pine with about 90 species among which six species are found in India. (N. East and N. West Himalayas) occurring in wild state. These are Pinus gerardiana (Chilgoza pine), P. Wallichiana (Blue pine or Kail), P.roxburghii (Chir pine), P.merkusii (Teenasserim pine), P.insularis (Khasi pine), and P.armandi (Armand's pine). In addition to these, 4 sps. of exotic pines, i.e., P.montana, P.laricia and P.sylvestris (Scotch pine) and P.strobus (white pine) have been introduced in India. P.excelsa are found at maximum height i.e., grow upto 3500 m above sea level.

Structure

External structure: Pinus is an evergreen, perennial plant of xerophytic nature. Mostly the species are tall and straight. The whorled branching gives a typical conical or excurrent appearance to the plant (due to apical dominance). The plant body is sporophyte and the plants are monoecious. The plant body is differentiated into roots, stem and leaves.

Root: A prominent tap root is present which does not penetrate deep into the soil. Lateral roots which develops later, grow extensively and help in anchoring the plant in the soil. Root hairs are scanty. Ectotrophic mycorrhiza *i.e.*, symbiotic association of some fungal hyphae with the ultimate branches of roots, is of common occurrence.

Stem: The stem is erect, thick, cylindrical and branched. The branching is **monopodial** type. The main stem is covered by scaly bark. Branches are developed from the buds present in the axil of scale leaves and appear to be in whorls. These branches develop every year and help in calculating the age of the plant.

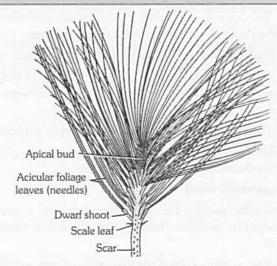

Fig: 1.6-23 A long shoot with dwarf shoots (spurs) of Pinus roxburghii

Branches are of two types:

- (1) Long shoots or Branches of unlimited growth: These have apical buds, grow indefinitely in whorls each year from the buds in the axil of scale leaves. These shoots spread out horizontally and bear scale leaves on them.
- (2) Dwarf shoots or Branches of limited growth: These branches lack apical buds and grow for a definite or short period. They arise in the axil of scale leaves on long shoots. The scale leaves on dwarf shoots are called the cataphylla possess a distinct midrib.

Leaves : The leaves are of two types i.e., **dimorphic** – scale leaves and foliage leaves.

Scale leaves: The scale leaves are small membranous and brown. They are present on both types of branches (i.e., long and dwarf shoots). Scale leaves are non-photosynthetic. These protect the young buds.

Foliage leaves: The foliage leaves are green, needle like and are born at the tips of the dwarf shoots only. Their size and number is different in different species. The dwarf shoot with needles is called a **spur**. On the basis of number of needles, spur is of different types as:

Monofoliar (with one needle), e.g., P. monophylla.

Bifoliar (with two needles), e.g., P. merkusii and P. sylvestris.

Trifoliar (with three needles), e.g. P. gerardiana and P. roxburghii.

Pentafoliar (with five needles), e.g., P. wallichiana, P. excelsa.

Internal structure

(1) **Root**: The young root of *Pinus* is identical with the dicot root. A T.S. of root reveals the following structures.

Epiblema: It is the outermost layer of compactly arranged cells. It gives out many thin and unicellular root hair.

Cortex : It is composed of many layeres of thin walled parenchymatous cells.

Endodermis: A single layer of suberized cells.

Pericycle: Endodermis is followed by multilayered pericycle.

Vascular tissues: Radial vascular bundles are present.

Xylem : Exarch condition with bifurcated (Y-shaped) protoxylem. Resin canal is present between two arms. Xylem is devoid of vessels.

Phloem: Alternating with the xylem groups are present phloem patches. Companion cells are absent.

Pith: Pith is generally absent. If present, it is very small and made-up of parenchymatous cells.

Secondary growth: In young roots, cambium is absent but at maturity below the phloem patches, arches of cambium are formed. It cuts off secondary xylem on the inner side and secondary phloem on the outer side.

The cells of the outermost layer of pericycle form cork cambium (phellogen), which cuts off phellem (cork) on the outer side and phelloderm (secondary cortex) on the inner side. Finally epiblema ruptures and the cork layer is exposed.

(2) Stem: T.S. of a young shoot shows following tissue.

Epidermis: It is the outermost layer made up of small compactly arranged cells (heavily cuticularised).

Hypodermis: Below epidermis 4–5 layers of sclerenchymatous cells constituting hypodermis.

Cortex : Inner to the hypodermis is a wide zone of cortex, some cells are filled with tannin.

Endodermis: It is the innermost layer of the cortex, madeup of single layer of cells.

Vascular cylinder (Stele): It is of eustelic type having a ring of 5–8 closely arranged vascular bundles. Vascular bundles are conjoint, collateral and open.

Xylem: It is endarch, consists of only tracheidal cells, vessels are absent. Therefore wood is known as non-porous.

Protoxylem consists of annular and spiral tracheids. Metaxylem tracheids have uniseriate bordered pits on their radial walls. These are also having bars of sanio.

Phloem: It is situated on the outer side of vascular bundle and is made-up of phloem parenchyma and sieve cells. Companion cells are lacking.

Cambium: In between the xylem and phloem of each vascular bundle, there is a strip of intrafascicular cambium.

Medullary ray: In between the vascular bundles is a zone of parenchymatous cells connecting the pith and the cortex.

Pith: In the centre of the stem is a zone of thin-walled parenchymatous cells known as pith. Some of the pith cells are filled with resinous substances.

Secondary growth: Secondary growth is similar to that of dicot stem. Wood is pycnoxylic and monoxylic. Vascular rays are linear (uniseriate) but fusiform (multiseriate) area of passage of resin ducts. These cambium cells cut cells on the inner side forming secondary xylem and on outer side secondary phloem.

The ring of primary cambium remains active only for a year. The activity of the cambium stops in the winter season and again resumes in the following spring. The secondary xylem thus formed clearly shows a number of annual rings. Each annual ring consists of a zone of spring wood and autumn wood.

Autumn wood: It is formed during autumn season and the cells of this wood are smaller, squarish and thick.

Spring wood : It is formed during spring season. The cells of this wood are thinner, large and polygonal. The wood is termed as pycnoxylic (compact and hard).

(3) **Leaf (Needle):** The outline of foliage leaf varies according to the number of needles in the spur, i.e., in monofoliar spur of *P. monophylla*, it is circular, in bifoliar spur of *P. sylvestris*, it is semicircular and is triangular in trifolial spur of *P. roxburghii*. Internal structure of the needle is same in all species of *Pinus*. Needle shows xerophytic characters.

Epidermis : It has a single-layered, thick-walled epidermis, covered with thick cuticle and is interrupted by sunken stomata throughout the surface (amphistomatic).

Stomata: Each stoma has two guard cells and two subsidiary cells. It opens outside into a cavity called vestibule and inside into a substomatal cavity.

Hypodermis: Below the epidermis is present a few layered thick sclerenchymatous hypodermis. It helps in mechanical support.

Mesophyll: There is no differentiation into palisade and spongy parenchyma. The cells of this region are thin-walled, parenchymatous, polygonal, compactly arranged, having chloroplasts and starch grains. Peg-like infoldings arise from the inner surface.

Vascular cylinder: It is surrounded by single-layered endodermis having barrel-shaped cells with casparian strips.

Pericycle: Just below the endodermis is multilayered pericycle having a T-shaped mass of sclerenchymatous cells between two vascular bundles. Transfusion tissue occurs on the side. Each bundle is collateral, open and endarch.

The needle of *P.monophylla* has a **single** vascular bundle whereas in *P.roxburghil*, the number is **two**.

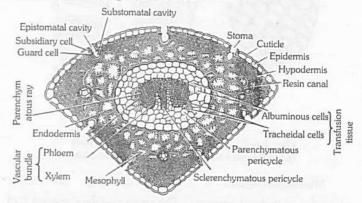

Fig: 1.6-24 T.S. neddle of Pinus roxburghii

Reproduction

Pinus reproduces only by means of spores. Unlike Cycas, here the micro and megasporophylls form compact male and female cone or strobilus respectively.

Pinus plant is sporophyte (2x), heterosporous (producing two type of spores – microspore and megaspore), monoecious (male and female cones are borne on same plant) and autoecious (male and female cones are borne on different branches).

(1) Male cone or Staminate strobilus: The male cones are borne in a cluster on a branch of unlimited growth behind the apical bud, in the axil of a scale leaf. A male cone is, thus, equivalent to a dwarf shoot.

In a cluster, there may be 15–140 male cones. The male strobilus is an ovoid structure measuring 2 to 4 cm. in length and 0.5 to 0.7 cm. in diameter. A cone consists of a central axis bearing 60–135 microsporophylls in spiral manner. It is, therefore, comparable to male flower of angiosperms.

Microsporophyll: The microsporophylls or 'stamens' are spirally arranged in a compact manner on the cone axis. The microsporophyll is a brown coloured triangular structure consisting of a short stalk or 'filament' and a leaf like flattened structure called 'anther'.

Each sporophyll is provided with two microsporangia on its abaxial surface. The terminal sterile portion of the sporophyll is turned upward to protect the upper sporangia. It is called apophysis. Some of the lower microsporophylls are sterile having no sporangia associated with them.

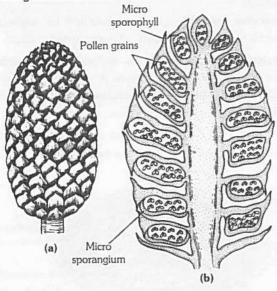

Fig: 1.6-25 (a) A young male cone of *Pinus* (b) Male cone in radial longitudinal section

Microsporangium: The microsporangia are sessile elongated, cylindrical, structures. The sporangial development is of eusporangiate type. Each sporangium consists of a 2–3 layered wall. The inner most wall layer is called tapetum, which encloses a mass of sporogenous tissue. The sporogenous cells divide and redivide and finally behave as microspore mother cells or pollen mother cells (PMC). The PMC undergo meiosis to form tetrahedral tetrads of microspores. The tapetum is a nutritive layer which degenerates at maturity of the anther.

(2) **Female cone (ovulate strobilus)**: The female cone is an elongated, ovoid structure comprising a central cone axis on which the ovuliferous scales and bracts are spirally arranged in acropetal order. Usually the cone is 15 – 20 cm. long but in *P. lambertiana* they are 60 cm. long. The female cones take three years time to develop and mature.

The cones are produced in clusters of 1 to 4 from places where normally dwarf or spur shoots have developed. They arise in a group of 1-4 cones on a long shoot in the axil of a scale leaf in place of a dwarf shoot. In the first year, the female cone is reddish-green measuring about $1-2\ cm$ in length having compactly arranged sporophylls. The second year cone is much larger, again with compact sporophylls. In the third year, the cone axis elongated and hence the sporophylls separate from each other.

Megasporophyll: Each megasporophyll is differentiated into two parts – Lower part is bract scale and upper part is ovuliferous scale.

Bract scales: These are small, dry, membranous structures attached with the cone axis directly. These are also known as carpellary or cover scales.

Ovuliferous scale: This is a woody, brownish structure borne on the dorsal side of the bract scale. Each ovuliferous scale is triangular with narrow basal part and upper broader part in the form of disc, known as apophysis. The apophysis appears to be rhomboidal and possesses a small point known as **umbo**.

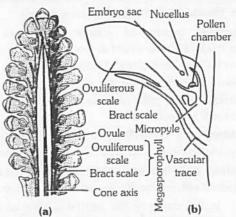

Fig: 1.6-26 Pinus (a) Longitudinal section of female cone (b) A megasporophyll

Megasporangium: Each ovule is an oval and anatropous structure consisting of a central mass of parenchymatous tissue, the nucellus, surrounded by a two lipped protective covering the integument which is united with nucellus except at the micropylar end where it prolongs to form a short tube beyond the nucellus. A small space is left in the upper region of nucellus below the integument, which is known as pollen chamber. Integument is differentiated into 3 layers although differentiation is not so distinct as in Cycas.

Outer fleshy layer: Made up of thin walled cells which disappears at maturity.

Middle stony layer: Very conspicious.

Inner fleshy layer: Inner fleshy layer is well developed.

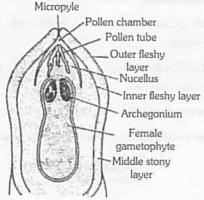

Fig: 1.6-27 Pinus: L.S. of ovule showing archegonia and pollen tubes

At the apex of the nucellus, a hypodermal cell gets enlarged and differentiated, it is called archesporial cell. The archesporial cell divides periclinally into an upper tapetal cell which forms **tapetum**, the nourishing layer, and the lower megaspore mother cell. This megaspore mother cell (sporogenous cell) divides reductionally to form a linear tetrad of haploid megaspores. Out of the four megaspores, three lying towards the micropyle degenerate. The chalazal one matures into a **functional megaspore**.

The gametophyte: The sporogenesis results in the formation of micro and megaspores representing the first gametophyte cells. They undergo gametogenesis so as to form the male and female gametophytes respectively.

Male gametophyte: The unicelled microspore undergoes three divisions of mircogametogenesis, so as to form a four-celled pollen grain or microgametophyte or male gametophyte.

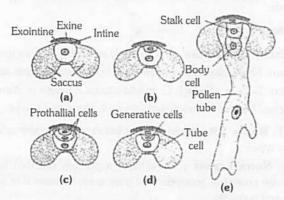

Fig: 1.6-28 Pinus: (a)-(e) Various stages of microgametogenesis

There are two prothallial cells, a generative cell and a tube cell. The pollen grains, at maturity are protected by three wall layers. The outermost wall layer, called exine or cappa is cutinised. the second wall layer is called exointine or capulla. It forms two

balloon like outgrowths, on either side, called wings or saccus. The third wall layer is thin and called intine or tenuitas. At maturity the microsporangia dehisce by a longitudinal slit and the pollen grains are dispersed at 4 – celled stage. Since, a large number of grains are set free from a cluster of male cones in the form of pale-yellow cloud the phenomenon is often described as **shower of sulphur** or **shower of golden dust**.

Female gametophyte: The functional megaspore enlarges. A vacuole develops in the centre and then its nucleus divides freely to form about 2000 nuclei. Initially, multinucleate tube like cells are formed called alveoli. Later, wall formation starts from periphery and proceeds towards the centre. As a result, cellular female gametophyte or female prothallus or megagametophyte or endosperm is formed. The cells of the nucellus surrounding the female gametophyte now get modified and form a nutritive layer called endosperm jacket or spongy layer. The 'endosperm' of Pinus is a haploid gametophytic tissue formed before fertilization.

Archegonium : Near the micropylar end, one to five archegonia are differentiated in the prothallus. Each archegonium at maturity consists of eight neck cells arranged in two tiers of four cells each and a venter having a small ventral canal cell and a large egg. The ventral canal cell disorganizes before fertilization. **Neck canal cells are absent**.

Pollination: The pollination in *Pinus* is anemophilous. The wings of pollen grains are helpful in pollination. Just before pollination the female cone axis elongates separating megasporophyll from each other. This fascilitates pollen grains to reach ovules. There is a long interval of about a year between pollination and fertilization.

Post pollination changes in the male gametophyte: The exine ruptures and the intine protrudes out to form the pollen tube that grows through the nucellar tissue. Simultaneously, the generative cell divides to form a stalk cell and body cell. The body cell then divides to form two male gametes, which are non-flagellate.

Fertilization: The mode of fertilization was discovered by Goroschankin (1883). After reaching the neck of the archegonium, the tip of the pollen tube ruptures releasing the two male gametes. The ventral canal cell degenerates and the neck cell split apart. Out of the two, one male gamete fuses with the egg to form the zygote. The second male gamete along with the stalk and body nuclei disintegrate. This type of fertilization is called siphonogamous fertilization.

Embryogeny: The proembryonal development in *Pinus* was studied by Buchholz (1918). The zygotic nucleus moves toward the base and then divides to form four nuclei. These nuclei organise into four quadrately arranged (diagonally opposite) cells with open upper end. The four cells divide simultaneously thrice to form four tiers of four cells each. These tiers are designated from top downwards as open tier, rosette tier, suspensor tier and apical tier. Since only a part of the oospore is involved in the formation of the embryo, the development is said to be meroblastic.

The cells of suspensor tier elongate pushing the embryonal cells into the 'endosperm'. The four suspensor cells due to considerable elongation may become coiled. These cells may divide transversely to form secondary suspensor or **embryonal** tubes.

Another type of polyembryony found in *Pinus* is simple polyembryony *i.e.*, when more than one embroys are developed as a result of fertilization of different archegonia. Thus in *Pinus* although both types of polyembryony are found but at maturity seed contains only one embryo as food is not sufficient for survival of many embryos. The embryo soon gets differentiated into radicle, plumule, hypocotyl and cotyledons. The number of cotyledons is always more than two (Schizocotyly).

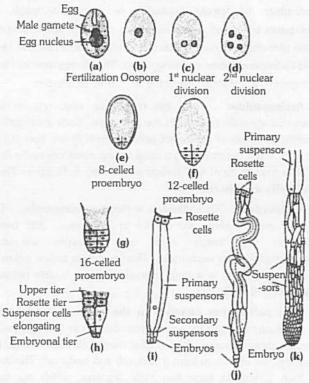

Fig: 1.6-29 Pinus: Embryogeny

Seed formation: Seed of *Pinus* is winged. The wing (saccus) develops from the upper surface of ovuliferous scale. Seed has thin with hard outer coat, which is peeled off, a stony coat, papery coat, cap like perisperm and food laden endosperm which encloses a central embryo. Embryo possesses 9–14 cotyledons (*P.roxburghii*). A seed represents three generations – parent sporophyte (testa, tegmen and perisperm, if present), new sporophyte (embryo) and female gametophyte or endosperm.

Seed germination: The seeds may remain dormant for several years. The germination of seed occurs when the environmental conditions are favourable. The radicle protrudes out through the micropyle and enters the soil forming the primary root. The plumule comes out and along with cotyledons it is pushed in air due to elongation of hypocotyl. The germination is, therefore, epigeal. The plumule forms a few juvenile leaves or prophylls.

The juvenile leaves are spirally arranged on the branch of unlimited growth. Long shoots arise in their axis. Later on, they dry up as scales. The rate of growth of *Pinus* is quite slow.

Economic importance

- (1) Seeds of some species are edible e.g., P. gerardiana (chilgoza), P. edulis.
- (2) Fossilized resin (amber) is obtained from P. succinifera and is of great commercial value.
 - (3) Some species of Pinus are cheap source of cellulose.
 - (4) Some species are used for manufacture of paper.

Habitat

Cycas is an evergreen palm-like plant. It is the only genus of family Cycadaceae represented in India. Cycas has approximately 20 species found in Australia, New Zealand, Japan, China, India, Burma (Myanmar) and Pacific Islands.

In India, four *Cycas* species are common in Odisha, Bengal, Assam, Tamilnadu, Karnataka and Andaman.

- (1) Cycas revoluta: It is a native of China and Japan and is locally called Tesso. In our country, it is called 'Sagopalm'. Due to its primitive characters, it is also called living fossil. It is upto 10 ft tall.
- (2) Cycas circinalis: Plants are about 12 to 15 ft tall and distributed upto 3500 ft. In Hindi, it is called as Janglimadan mast-ka-phul.
- (3) Cycas rumphii: Plants are about 12 ft tall. It is also cultivated in Indian gardens. In Tamil, it is called Kama, Paiyindu.
- (4) Cycas beddomei: It is found in Trimula-hills of Andhra Pradesh.

Structure

External structure: It looks very much like a palm tree or a tree fern, hence also called palm fern. Fully grown plants attain a height of 2-5 m although C. media attains a height of 20m. The main plant body is differentiated into root, stems and leaves.

- (1) **Roots**: Roots arise from lower part of stem and are of two types:
- (i) Normal roots: These form a primary tap root system. These are positively geotropic and their main function is to absorb water and nutrients.
- (ii) **Coralloid roots:** From the lateral branches of the normal roots are formed dichotomously branched, apogeotropic, bluish green coralloid roots. *Anabaena cycadacearum*, *Nostoc* and bacteria are found in their cortex. It is an example of symbiosis. It helps in fixation and absorption of nitrogen. As these roots possess lenticels, they also help in respiration.

- (2) **Stem :** Stem is thick, cylindrical, columnar, small, aerial and unbranched. It is covered with persistent leaf bases and scale leaves, which are found in alternate whorls. There is a crown of foliage leaves at the apex of the plant.
 - (3) Leaves: Cycas has two types of leaves (dimorphism).
- (i) **Scale leaves**: These are reduced form of foliage leaves without lamella and are arranged in a compact spiral and alternate manner around the apex and bears no reproductive structures. These are protective in nature. A single scale leaf is a brown, dry, woody, triangular structure, covered with brown hairs or ramenta.
- (ii) **Foliage leaves**: These are brown scales and green unpinnately compound present on the apex of the plant forming a crown. These leaves are upto 3 metres in *C. circinalis*. Leaves are leathery and thick, some leaflets at the base of the rachis are reduced to spines. These are mainly photosynthetic in nature. Leaves in *Cycas* show xerophytic characters.

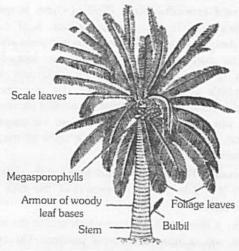

Fig: 1.6-30 External morphology of Cycas

Internal structure

(1) Root

Normal root : The structures of normal root resembles dicotyledonous root. T.S. of normal root reveals the following structures.

Epiblema : This is the outermost layer with unicelled root hairs.

Cortex : Just below the epiblema is multilayered parenchymatous cortex. Some tannin cells are present in the cortex.

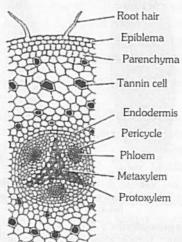

Fig: 1.6-31 T.S. normal root of Cycas

Endodermis: Below the cortex is present endodermis which is made up of barrel-shaped cells and below it is a layer of pericycle.

Vascular tissues: It consists of xylem and phloem which are radially arranged, i.e., on different radii.

Pith: It is generally absent.

Secondary growth: It is like dicotyledonous plants.

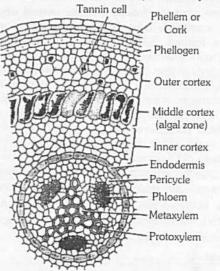

Fig: 1.6-32 T.S. coralloid root of Cycas

Coralloid root : Structure of stele is similar to normal roots but cortex is divided into three zones :

Outer cortex: Having several layers of parenchymatous cells.

Middle cortex (Algal zone): Filled with blue green algae, Anabaena and Nostoc.

Inner cortex : Having several layers of parenchymatous cells. Roots are diarch, triarch and sometimes polyarch.

(2) Stem: It resembles a dicotyledonous stem having the following tissues:

Epidermis: It is the outermost incomplete layer ruptured due to persistent leaf bases. It is made up of compactly arranged thick-walled cells.

Cortex: Cortex is large, thin-walled, parenchymatous, having a number of mucilage canals. Starch grains are found in the cortex.

Endodermis and pericycle: These layers are not very clear.

Stele: Vascular cylinder is very small having numerous small closely arranged vascular bundles, which are conjoint, collateral and open. Xylem is endarch and consists of tracheids, which have spiral thickening in protoxylem and scalariform thickenings in metaxylem. Phloem is devoid of companion cells. Albuminous cells are found in phloem.

Leaf traces: There are several leaf traces present in the cortex. Four vascular bundles enter the base of leaf, two of these are direct and other two arise from the stele of opposite side and after making semicircle, they enter the leaf. These indirect leaf traces are known as girdling leaf traces or leaf girdles.

Pith: It is large, parenchymatous and is having a number of mucilage canals. Starch grains are also found in pith.

Secondary growth: The secondary growth in initiated by the formation of a cambium ring due to the development of interfascicular cambium strips and their subsequent joining with the intrafascicular cambium. This ring cuts secondary xylem on the inner side and secondary phloem on the outer side in addition to secondary medullary rays on both sides. This cambium ring now ceases to function another cambium now arises from pericycle or inner layers of cortex.

The new cambium functions in the normal way like the old one. Thus, concentric rings of secondary xylem and secondary phloem are formed. Such a wood is called as polyxylic i.e., comprising more than one xylem cylinders. Due to the presence of alternating rings of thin walled tissue (phloem) the wood of xylem remains loose and hence it is described as manoxylic. The growth in the extrastelar region takes place by the formation of a phellogen (cork cambium) which cuts off phellem (cork) on the outer side and phelloderm (secondary cortex) on the inner side. The three layers jointly constitute the periderm. The secondary growth pattern of *Cycas* resembles some dicots showing abnormal secondary growth. Secondary wood is devoid of vessels.

The secondary xylem is made up of tracheids showing multiseriate bordered pits. Bars of sanio have been observed by Sifton, 1915 in the tracheids of *C. revoluta*. The secondary phloem comprises sieve cells and fibers.

(3) Leaf

(i) **Rachis**: The cross section of the rachis is almost circular with two depressions on upper lateral sides where the leaflets are attached.

Epidermis: The outermost layer is epidermis with thick cuticle having stomata.

Hypodermis : Epidermis is followed by a well developed hypodermis, differentiated into outer chlorenchymatous and inner sclerenchymatous regions.

Ground tissue : Below the hypodermis is well developed parenchymatous ground tissue with mucilage canals. The vascular bundles are arranged forming an inverted omega (Ω). Each vascular bundle is surrounded by a sclerenchymatous sheath and is conjoint, collateral and open. In most parts of the rachis, xylem is mesarch, i.e., centripetal xylem towards periphery and two patches of centrifugal xylem one on each side of protoxylem of centripetal xylem. Outside the centrifugal xylem is cambium and then phloem towards periphery.

(ii) **Leaflet**: Each leafleat is sessile has one midrib and no lateral veins and in *C. revoluta* the margin is curved inwardly. In young condition young leaves show circinate ptyxis like fern leaves.

Epidermis : Epidermis is single layered with thick cuticle. The upper epidermis is complete whereas the lower epidermis is interrupted by several stomata present only in the region of blade (hypostomatic). Upper and lower epidermis are covered by layer of thick cuticle.

Hypodermis: Just below the upper epidermis, there are several layers of sclerenchymatous hypodermis while above the lower epidermis it is present only in the midrib portion.

Mesophyll: Mesophyll is differentiated into palisade parenchyma on upper side and spongy parenchyma on lower side. Palisade tissue is made up of vertically elongated cells without intercellular spaces. Both tissues contain chloroplasts.

Vascular bundle : In the midrib there is a large vascular bundle. The vascular bundle is collateral and closed. The xylem is mesarch, i.e., diploxylic condition with centripetal and centrifugal xylem.

Transfusion tissue : On each side of the midrib in between the palisade and spongy tissues is present transfusion tissue made up of horizontally arranged tracheids which supply water and mineral to mesophyll tissue upto margins.

Reproduction

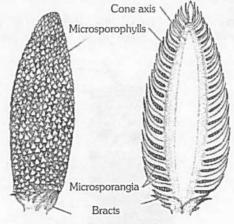

Cycas plants are dioecious and reproduce by following methods:

- (1) **Vegetative propagation**: It occurs by means of bulbils (resting adventitious buds) which are produced on the stem in the axil of scale leaves. They break up from the parent plant and germinate to give rise to new plant.
- (2n) and dioecious. The sexual reproduction is of oogamous type, i.e., takes place by the fusion of distinct male and female gametes. The male and female gametes are formed by the germination of micro and megaspores which are born on microsporophylls and megasporophylls. The microsporophylls are grouped together to form a compact conical structure called male cone, whereas the megasporophylls are not aggregated to form a cone, they are produced at the apex of the stem in succession with the leaves.

Male cone: The male cones are borne every year singly at the apex of the male plant. The growth of the male plant is, therefore, checked.

Later on, a lateral bud develops which pushes the male cone to one side and occupies a terminal position. The process is repeated during the formation of subsequent male cones. As such, the growth pattern of male plant is sympodial.

The male cone is a shortly stalked, oval or elliptical structure measuring about $40-60\ cm$ in length. It may sometimes attain a length of 75 cm. in C. circinalis. Each cone consists of a central axis bearing numerous microsporophylls arranged in spiral manner.

(a) (b)
Fig: 1.6-33 Cycas: (a) External view of male cone
(b) L.S. of male cone

Microsporophylls: They are wedge - shaped structures with a slightly broad base. They are soft and fleshy in the younger stages. At maturity, they are hard and woody. They

measure about $3-4\ cm$. in length and $1.2-2.3\ cm$. in width. They bear sori of sporangia on the abaxial (lower) surface. The terminal sterile portion of the sporophyll is called **apophysis**. In the apophyseal region the sporophyll gradually tapers and points upward.

Microsporangium : The microsporangia are borne in sori on the abaxial surface of the sporophyll. Each sorus contains 2-6 microsporangia. The number of microsporangia may be upto 700 in *C.circinalis*, 1000 in *C. revoluta* and 1150 in *C.media*. In between the sporangia are present uni or bicelled epidermal hair. The microsporangia are short-stalked, oval or elliptlical structures. The development of the sporangium is of eusporangiate type. Each sporangium consists of a 5-6 layered wall. The outer most wall layer is called as exothecium whereas the innermost layer is the tapetum.

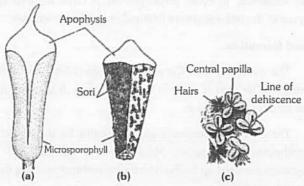

Fig: 1.6-34 Cycas: (a) Dorsal view of microsporophyll
(b) Ventral view of microsporophyll
(c) Microsporangia in sori (undehisced)

The tapetum encloses the sporogenous tissue. The sporogenous cells divide and re-divide to form the microspore mother cells or pollen mother cells (PMC). The PMC undergo meiosis to form tetrahedral tetrads of spores. The cells of exothecium develop a thickening along their radial and inner tangential walls. The cells of tapetum and inner wall layers degenerate at maturity to provide nutrition to the developing pollen grains. The wall of a mature sporangium, thus comprises exothecium only.

Megasporophyll: The megasporophylls are spirally borne in acropetal order on the female plant. Since they are loosely arranged, there is no female cone formation. Each megasporophyll is regarded as a **modified foliage leaf** and is about 5-10 inches long. In the female plant therefore, the apical meristem remains unaffected. Hence, the growth pattern in the female plant is monopodial.

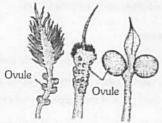

Fig: 1.6-35 Megasporophylls of different species of Cycas

The megasporophylls are flat, dorsiventral structures distinguishable into a proximal stalk or rachis part and a distal lamina. The margin of lamina is serrate or dentate in *C. circinalis*,

C. beddomei and C. rumphii. In the upper part of the rachis are present 1-6 pairs of ovules, laterally. This number is variable in different species e.g., 1-6 pairs in C. revoluta, C. circinalis and only one pair in C. normanbyana.

Megasporangium (Ovule): The ovules of Cycas are largest in nature, can be seen by naked eyes. In C. circinalis, the ovules are largest in size, i.e., about 6 cm in length and 4 cm in diameter.

The ovules are orthotropous and unitegmic. The main body of the ovule is nucellus, covered by a single thick integument except at the top where a small opening is left called micropyle.

The integument is distinguishable into three layers, an outer fleshy layer (sarcotesta), middle stony layer (sclerotesta) and inner fleshy layer (sarcotesta). The outer and inner fleshy layers are vascularised as also the nucellus by separate bundles. The apex of the nucellus develops a beak-like process, the nucellar beak, which projects into the micropyle.

Somewhere in the deep layers of nucellus a megaspore mother cell in differentiated. It has a prominent nucleus and dense cytoplasm. It undergoes meiosis to form a linear tetrad of megaspores. Of these, three micropylar megaspores degenerate and the lowest functions. The functional megaspore has a thick papillate outer wall called exospore and a thin, fibrillar inner wall, the endospore.

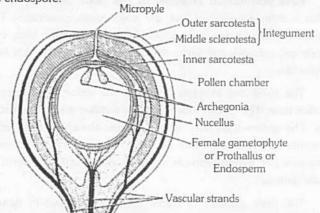

Fig: 1.6-36 L.S. megasporangium (ovule) of Cycas

The gametophyte: As a result of sporogenesis, the micro and megaspores are formed. They are the first gametophytic cells. The microspores give rise to the male gametophyte whereas the megaspores form the female gametophyte. The gametophytes reproduce sexually.

Male gametophyte: The unicelled microspore undergoes two divisions of microgametogenesis and as a result three cells are formed. These three cells are serially designated as tube cell, generative cell and prothallial cell. At this stage the pollen grain is double layered. The outer wall exine is much thicker than intine. The microsporangium dehisces by a longitudinal slit and pollen grains are dispersed at **3-celled stage**.

Female gametophyte: The nucleus of the functional megaspore divides freely to form a free-nuclear gametophyte. A vacuole appears in the centre. Wall formation now begins from periphery and gradually proceeds towards the centre. As a result,

cellular female prothallus or megagametophyte or endosperm is formed. The 'endosperm' in *Cycas* is a haploid gametophytic tissue formed before fertilization. This is nutritive in function. Simultaneously, a tiny space develops on the upperside of the ovule between nuclellus and the female gametophyte due to degeneration of certain nucellar cells. This is called as archegonial chamber.

Archegonium : The archegonia are formed from the gametophytic cells lining the archegonial chamber. The number of archegonia formed in a gametophyte is variable e.g., 2-8 in C. revoluta, 3-6 in C. rumphii and 3-8 in C. circinalis. An archegonium consists of a two celled neck but there is no neck canal cell. There is no venter either. The egg and the ventral canal nucleus remain surrounded by the cells of prothallus. Cycas produces largest egg in the plant kingdom measuring $0.5\ mm$. in diameter.

Pollination: The pollination is anemophilous. The pollen grains of *Cycas* are light in weight and easily blown away by wind at 3-celled stage (prothallial cell, generative cell, tube cell). At the time of pollination, a large pollination drop comes out of micropylar end of ovule by disorganisation of nucellar beak. The pollen grains are entangled on this drop and as it dries, the pollens are drawn into the pollination chamber.

Post pollination changes in the male gametophyte: After a definite period of rest, the pollen grain germinates. The generative cell divides into a lower stalk cell and upper body cell. Body cell enlarges and forms several blepharoplasts, which later forms cilia.

The tube cell elongates, pierces the exine and forms a pollen tube. The pollen tube is slightly swollen and branched at tip. The pollen tube acts as haustorium absorbing food from nucellus. Body cell divides into two daughter cells and each daughter cell metamorphosis into one antherozoid or sperm or male gamete.

The male gametes of Cycas are largest (300μ) in nature, visible to naked eye and are oval in form, broad (top-shaped) and naked at posterior end and spirally coiled in the anterior half with thousands of small cilia. The sperms pass into pollen tube and reach the tip of the tube.

Fertilization

After reaching the archegonial chamber, the tip of the pollen tube ruptures releasing the two male gametes. Besides, the tube also discharges a fluid having high concentration. When an antherozoid touches the neck cells, it is sucked in violently. By the time the ventral canal nucleus has already degenerated. As a result of syngamy, the zygote is formed.

The fertilization in *Cycas* is, therefore, siphonogamous (by pollen tube) accompanied by zoidogamy (by flagellate gametes). Thus the fertilization brings to an end of the gametophytic generation and the zygote is the initial stage of sporophytic generation.

Embryogeny

The zygote, which is the first sporophytic cell, undergoes free-nuclear divisions. A vacuole develops in the centre pushing the nuclei to the peripheral position. In the upper region there are only a few nuclei but the lower region contains numerous nuclei. This is followed by wall formation that begins from periphery and proceeds to centre (centripetal). The cellular proembryo consists of –

Upper: Haustorial region, **Middle:** Suspensor region and **Lower:** Embryonal region.

Embryo consists of radicle, plumule, 2 cotyledons, haustorium and suspensor. In cycas polyembryony is often seen as egg of almost all the archegonia are fertilized and produce embryo.

Seed formation

The mature seed of *Cycas* is an orange-red or reddish-brown structure. The seed is covered by a thick testa. It is sweet in taste and emits pleasant odour.

These two characteristics are responsible for their zoochorus, (ornithochorous) dispersal. Major parts of nucellus and inner sarcotesta are used up by the developing embryo reducing them to thin, papery layers.

The embryo is distinguishable into a haustorial tip, a long suspensor, radicle, hypocotyl, plumule and two cotyledons.

Seed germination

There is hypogeal germination of *Cycas* seed. In germination, the radicle forms a tap root. The cotyledons remain in the endosperm under the surface of soil. The plumule grows up and forms some scale leaves and later foliage leaves. *Cycas* seed represents 3 generations:

Old sporophytic generation (represented by seed coat and nucellus), Female gametophytic generation (represented by endosperm), and Future sporophytic generation (represented by embryo).

Life history of *Cycas* is diplohaplontic. It shows heteromorphic or heterologous type of alternation of generations.

Economic importance

- (1) A starch called sago is obtained from the pith of *Cycas*, that is why *Cycas* is called **sago palm**. In Japan starch extracted from stem of *C. revoluta* is used for preparing saboodana.
 - (2) Seed of some Cycads are used as fodder for animals.
 - (3) Leaves are used for making mats and baskets.
 - (4) Cycas is an ornamental plants.
 - (5) Boiled young leaves are eaten as vegetables.

(6) Extract of young Cycas leaves are used in the treatment of many skin diseases.

The decoction of seeds is used as purgative. Tincture prepared from its seeds is used by Indians in headache, nausea, bad throat, etc.

Angiosperms

(Gk. Angeion = covered; sperma = seed)

Introduction

The angiosperms, or flowering plants, constitute the most dominant and ubiquitous vascular plants of present day flora which changed the green and yellow melancholy of the earth's vegetation by the colourful brightness and fragrance of their flower. The term angiosperm means 'enclosed seed' because the ovules or potential seeds are enclosed within a hollow ovary. In this respect they are considered most highly evolved and advanced as compared with the naked seeded gymnosperms.

Characteristic features

- (1) Angiospermous plants grow in almost every kind of habitats. In the deserts, these plants grow, flower, shed seeds and complete their life cycle in a few weeks of rainy season. Some flowering plants like Zostera, occur in shallow seas. A small orchid even lives underground. It survives as a saprophyte on decaying organic matter because of the mycorrhizal association which helps to obtain nourishment. In rain forests, some plants grow on the branches of other plants but do not obtain water or food from them. They are called epiphytes (e.g., Vanda).
- (2) The angiospermous leaves show reticulate or parallel venation forming areoles. The libriform fibres are present in the xylem and the companion cells are present in the phloem. The true vessels are present in the xylem of angiosperms.
- (3) The angiosperms produce flowers which normally consist of 4 whorls of appendages the two outer accessory and reproductive structure such as sepals and petals and the two inner essential parts stamens and carpels.
- (4) The stamens (microsporophylls) are bilaterally symmetrical. Each stamen consists of a filament and an anther.
- (5) The anthers produce tectate pollen grains with exine differentiated into rod-like columellae covered by a tectum.
- (6) In angiosperms, the insects and animals also act as pollinating agents. For this purpose the flowers possess bright and showy petals, edible pollen and nectar.
- (7) The carpels (= megasporophylls) are rolled and partly sterile so that they enclose the ovules within a hollow ovary that is connected with the stigma and style.
- (8) The female gametophyte is highly reduced and consists of single egg cell, two synergids, three antipodals and two polar nuclei. The archegonia are absent.

- (9) The most characteristic feature of angiosperms is double fertilization.
- (i) The male gamete fuses with the egg producing diploid zygote that develops into embryo or new sporophyte.
- (ii) Another male gamete fuses with the polar nuclei (triple fusion) resulting in the formation of triploid endosperm.
- (10) After fertilization, the ovules ripens into seeds and ovary ripens into fruits.

Size

- (1) **The smallest** angiosperm is *Wolffia*. The plant body of *Wolffia* consists of tiny flat oval green stem (phylloclade) having a few small roots. The plants are about 1 mm in diameter and found free floating in aquatic habitats like ponds, etc.
- (2) **The tallest** angiosperm is *Eucalyptus*. Their trees may attain a height upto 100 *meters* or more.
- (3) **Banyan** (*Ficus bengalensis*) tree covers a large area. It's slanting aerial branches spread in all directions. The tree spreads with the help of prop or pillar roots.

Longevity

Based on the duration of life, the plants are divided into following 4 categories :

- (1) **Ephemerals**: This category includes the plants which live only for a few weeks because of a very short growing season. Such plants are found near deserts or in very cold countries. For example, *Arabidopsis* species have a life span of 20–28 days.
- (2) **Annuals :** The plants of this category live and complete their life-cycle in a single favourable season. During this period, they grow in size, produce flowers, shed their seeds, undergo senescence and die. They pass the unfavourable period in the form of seeds. Many crop plants (e.g., wheat, rice, maize, etc.) are annuals. The smallest angiosperm Wolffia is an aquatic annual.
- (3) **Biennials**: The plants of this category complete their lifecycle in two favourable seasons (i.e., in two years). They grow vegetatively in the first season and produce flowers and set seeds in the next. Often they produce some storage organs, as in the sugar beet, where food is stored in their swollen roots.
- (4) **Perennials**: Plants of this category live for more than two years. Generally they live for many years and bear the flowers and fruits during specific seasons. Some perennials continue their vegetative growth for several years and produce fruits and seeds only once in their life time, *e.g.*, *Agave*, Bamboos, etc. They are called monocarpic. Others produce flowers and fruits every year after attaining a definite stage of maturity, *e.g.*, Mango, Lemon, Apple, etc. Such plants are called polycarpic.

Habit

Depending upon the habit of plants, the angiosperms belong to following categories :

- (1) **Herb**: These are small, soft, non-woody plants without persistent parts aboveground. The height of plants usually reaches upto 1 m. The plants may be annual (*Brassica*), biennial (Sugar beet) or perennial (*Canna*). The perennial herbs usually possess underground rhizomes which form the new aerial shoots every year. The plants of banana are perennial herbs.
- (2) **Shrubs**: These are woody plants of relatively low height (1-4 m). They typically branch at or near the base and do not have a main trunk, e.g., Rose. They are mostly perennial.
- (3) **Trees:** These are perennial woody plants with one main trunk. The trunk may or may not be branched. These are of the following types:
- (i) Caudex: The stem is unbranched and usually bears a crown of leaves at the apex. e.g., Date-palm.
- (ii) Excurrent: The lower part of stem is thicker which gradually tapers above. Branches arise from the main stem in acropetal succession and plant appears conical e.g., Pinus.
- (iii) **Deliquescent**: The apical bud of the main stem dies after some time and branches and sub-branches spread in different directions. e.g., *Tamarindus*, *Ficus*.
- (4) **Culms**: In these plants, nodes and internodes are extremely clear. Internodes of such plants are usually hollow. These plants are grasses but cannot be considered as herb or shrub or tree. e.g., Bambusa (Bans).

The plants of Angiosperms divided into two major groups as – Dicotyledons and Monocotyledons.

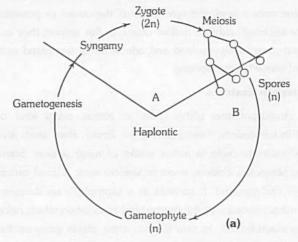

- (1) **Dicotyledons**: They show following distinguished characteristics.
 - (i) Tap roots found in the members of this group.
- (ii) The leaves in members of these class exihibit reticulate (net like) venation.
- (iii) The flowers are tetramerous or pentamerous having four or five members in the various floral whorls, respectively.
- (iv) The vascular bundles arranged in a ring, numbering 2-6, open and with cambium.
- (v) The seeds of dicotyledons are with two cotyledons as the name indicate.
- (2) **Monocotyledons**: They show following distinguished characteristics:
 - (i) Adventitious roots found in the members of this group.
 - (ii) The leaves are simple with parallel venation.
- (iii) The flowers are trimerous having three members in each floral whorl.
- (iv) The vascular bundles scattered in the ground tissue, many in number, closed and without cambium.
- (v) The seeds of monocotyledons are with one cotyledons as the name indicate. e.g., Cereals, bamboos, sugarcane, palms, banana, lillies and orchids.

Plant Life Cycles and Alternation of Generations

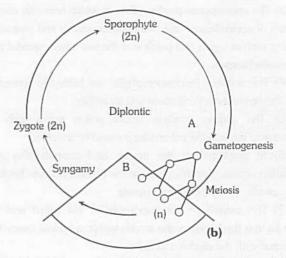

In plants, both haploid(n) and diploid(2n) cells can divide by mitosis. The haploid plant body produces gametes by mitosis (cell division). This plant body represents a gametophyte. After fertilisation the zygote also divides by mitosis to produce a diploid sporophytic plant body. Haploid spores are produced by this plant body by meiosis. These in turn, divide by mitosis to form a haploid plant body once again. Thus during the life cycle of any sexually reproducing plant, there is an alternation of generations between gamete producing haploid gametophyte and spore producing diploid sporophyte.

The different patterns of life cycle in different plants are as follows:

(i) Haplontic life cycle is exhibited by many algae like Spirogyra, some Chlamydomonas species and Volvox. Sporophytic generation is represented only by the one-celled zygote. There are no free living sporophytes. Meiosis in the zygote results in the formation of haploid spores. The haploid spores divide mitotically and form the gametophyte. The dominant, photosynthetic phase in such plants is the free living gametophyte. This kind of life cycle is termed as **haplontic**.

(ii) On the other extreme, is the type wherein the diploid sporophyte is the dominant, photosynthetic independent phase of the plant. The gametophytic phase is represented by the single to few-celled haploid gametophyte. This kind of life cycle is termed as diplontic. All seed-bearing plants i.e., gymnosperms and angiosperms, follow this pattern.

(iii) Bryophytes and pteridophytes, interestingly, exhibit an intermediate condition (Haplo-diplontic) both phases are multicellular. However, they differ in their dominant phases.

A dominant, independent, photosynthetic, thalloid or erect phases is represented by a haploid gametophyte and it alternates with the short-lived multicelluler sporophyte totally or partially dependent on the gametophyte for its anchorage and nutrition. All bryophytes represent this pattern.

The diploid sporophyte is represented by a dominant, independent, photosynthetic, vascular plant body. It alternates with multicellular, saprophytic/ autotrophic, independent but short-lived haploid gametophyte. Such a pattern is known as haplo-diplontic life cycle. All pteridophytes exhibit this pattern

Interestingly, while most algal genera are haplontic some of them such as *Ectocarpus*. *Polysiphonia*, kelps are haplo-diplontic. *Fucus*, an alga is diplontic.

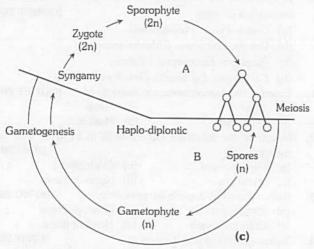

Fig: 1.6-37 Life cycle patterns: (a) Haplontic (b) Diplontic (c) Haplo-diplontic

Tips & Tricks

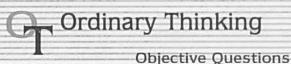

- Father of Indian phycology: "M.O.P. lyengar."
- Thallophytes: The term was coined by Endlicher (1863) for placing algae, fungi and bacteria in it. Plant body of thallophytes is called thallus. It does not show differentiation of stem, leaves and roots. An embryo stage is absent. They are most primitive members of plant kingdom.
- Algae: The term was coined by Linnaeus (1754) for hepaticae and others but was used for its present meaning by A.L. de Jussieu (1789).
- Multicellular algae are revolutionary older than land pants.
- The first algal antibiotics chlorellin was extracted from chlorella.
- Cymbella used as a bacterial filter.
- Bryophytes: The term coined by Robert Braun (1864). Bryophytes are nonvascular plants with multicellular sexorgans.

- Bryology: The science dealing with bryophytes. S.R. Kashyap is father of Indian Bryology.
- Sporogonium: Sporophyte of Bryophytes which is parasitic over gametophytic plant body and its mainly meant for producing meiospores.
- Erect gametophyte of bryophyte is called gametophore.
- A capsule of Marchantia forms about 3,000,000 spores.
- Tallest bryophytes is Dawsonia.
- Tracheophytes: Sinnott (1935) coined the term to include vascular plants. (Pteridophytes and seed plants).
- Elaters: Elongated structures which help in spore dispersal.
- Cormophytes: Plants with distinction of stem, leaves and roots.
- Rudimentary seed habit occurs in Selaginella.
- Acrostichum aureum is a halophyte.
- Marsilea occurs as terrestrial, amphibious as well as aquatic plant.
- Salvinia is an aquatic pteridophyte weed.
- Equisetum is commonly known as Horse tails or Scouring rushes. A few species of Equisetum contain gold.
- Lycopodium is commonly known as club moss.
- Chondrus (Irish moss) is used in the preparation of various pharmaceuticals including laxatives and cosmetics.
- Vessels are major water conducting cell in angiosperm.
- The primitive haplochelic type of stomata are found in Cycas, Pinus, Ginkgo, Ephedra etc.
- \angle Ophioglossum (Adder's tongue fern) has maximum number of chromosomes (2n = 1262) in plant kingdom.
- The vascular supply given for a leaf from the main stele is called leaf trace.

- In gymnosperm endosperm is haploid and develops before fertilization.
- The only gymnosperms showing limited growth is Welwitschia (45 cm tall).
- Embryosac of gymnosperm is haploid.
- In gymnosperm the arrangement of megaspore tetrad is linear.
- Sulphur shower is due to pollen of pinus/cedrus.

- Bamboo or Agave are monocarpic perennial plants.
- Vessels are major water conducting cell in angiosperm.
- Double fertilization is a unique character of angiosperm.
- Anthophytes: Plants with flower/ flowering plants.
- Marine angiosperm : Zostera, Thalassia.
- National tree: Ficus bengalensis (Banyan).
- Takakia is a bryophyte without rhizoids. It bears mucilage hairs for water conduction.
- Cereus giganteus is largest cactus of 52 feet height.
- F.E. Fritsch (1935) divided algae into eleven classes mainly on the basis of pigmentation, reserve food and flagellation thallus structure, modes of reproduction and life cycles.
- Therophytes plants are those which survive in winter as a seed and complete their life cycle between the spring and autumn.
- In ferns, leaves are photosynthetic as well as reproductive in function.
- Sperms of Cycas and Ginkgo are motile and multiciliated.
- Salvinia is an aquatic weed and called sorrow of Kashmir.

Algae (General)

- 1. Who is regarded as the "Father of Indian Phycology"
 - [BHU 1999] (b) Prof. J.N. Mishra
 - (a) Prof. M.O.P. Iyenger (c) Prof. R.R. Mishra
- (d) Prof. R.N. Singh
- 2. Phycology is the study of [AMU (Med.) 1998, 2005; KCET 2002; Odisha JEE 2005; RPMT 2006]
 - (a) Algae
- (b) Fungi
- (c) Bacteria
- (d) All the above
- 3 Who is popularly known as the "Father of Phycology"
 - (a) Fritsch
- (b) Papenfus
- (c) Smith
- (d) Morris

66. Batrachospermum is found in

[MHCET 2001]

- (a) Marine water
- (b) Fresh water
- (c) Tree
- (d) Arctic zone
- 67. In oogamy, fertilization involves

[CBSE PMT 2004]

- (a) A large non-motile female gamete and a small nonmotile male gamete
- (b) A large motile female gamete and a small non-motile male gamete
- (c) A small non-motile female gamete and a large motile male gamete
- (d) A large non-motile female gamete and a small motile male gamete
- 68. Agar agar is obtained from

[BVP 2001, 02; AFMC 2004; CPMT 2004]

- (a) Green algae
- (b) Red algae
- (c) Brown algae
- (d) Blue green algae
- 69. Agranal chloroplast are found in

[DPMT 2004]

- (a) Bryophytes
- (b) Gymnosperms
- (c) Green algae
- (d) Angiosperms
- **70.** Algae attached to stone is called
- [Odisha JEE 2004]

- (a) Epilithic
- (b) Epifolic
- (c) Coenolithic
- (d) None of these
- 71. Monoecious plant of Chara shows occurrence of

[NEET 2013]

- (a) Upper oogonium and lower antheridium on the same plant
- (b) Antheridiophore and archegoniophore on the same plant
- (c) Stamen and carpel on the same plant
- (d) Upper antheridium and lower oogonium on the same plant
- **72.** Select the wrong statement

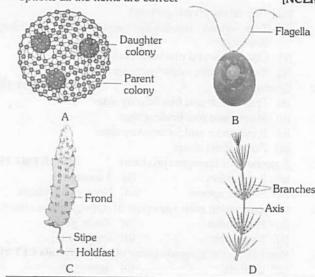

[NCERT; NEET 2013]

- (a) Chlamydomonas exhibits both isogamy and anisogamy and Fucus shows oogamy
- (b) Isogametes are similar in structure, function and behaviour
- (c) Anisogametes differ either in structure, function or behaviour
- (d) In Oomycetes female gamete is smaller and motile, while male gamete is larger and non-motile
- 73. Which of the following is not correctly matched for the organism and its cell wall degrading enzyme [NEET 2013]
 - (a) Fungi Chitinase
- (b) Bacteria Lysozyme
- (c) Plant cells Cellulase
- (d) Algae Methylase
- 74. Syngamy can occur outside the body of the organism in

[NEET (Karnataka) 2013]

- (a) Mosses
- (b) Algae
- (c) Ferns
- (d) Fungi

75. Observe the diagram A, B, C, D. In which one of the four options all the items are correct [NCERT]

	A	В	C	D
(a)	Chlamydo- monas	Chara	Laminaria	Volvox
(b)	Laminaria	Volvox	Chlamydo- monas	Chara
(c)	Chara	Laminaria	Volvox	Chlamydo- monas
(d)	Volvox	Chlamydo- monas	Laminaria	Chara

76. Which one of the following is wrong about Chara

[CBSE PMT 2014]

- (a) Upper antheridium and lower oogonium
- (b) Globule is male reproductive structure
- (c) Upper oogonium and lower round antheridium
- (d) Globule and nucule present on the same plant
- 77. Male gametes are flagellated in [AIPMT (Cancelled) 2015]
 - (a) Anabaena
- (b) Ectocarpus
- (c) Spirogyra
- (d) Polysiphonia
- 78. Which one of the following statements is wrong

[NEET (Phase-II) 2016]

- (a) Laminaria and Sargassum are used as food
- (b) Algae increase the level of dissolved oxygen in the immediate environment
- (c) Algin is obtained from red algae, and corrageenan from brown algae
- (d) Agar-agar is obtained from Gelidium and Gracilaria
- 79. An example of colonial alga is

(b) Volvox

- (a) Chlorella (c) Ulothrix
- (d) Spirogyra

Spirogyra and Ulothrix

- Two adjacent filaments of Spirogyra affinis having 10 cells each are participating in reproduction. How many new Spirogyra plants are produced during sexual reproduction [EAMCET 2009]
 - (a) 5

(b) 10

(c) 20

- (d) 40
- Spirogyra increases its body length by the division of [AFMC 2001]
 - (a) The apical cell
 - (b) The basal cell
 - (c) Every cell of the body
 - (d) Accumulation of food in his body

UNIVER	150 Plant Kingdom		
3.	Sexual reproduction in Spirogyra involves fusion of	17.	In Spirogyra, ladder like structure is formed in
	[MP PMT 1994; BVP 2003]		(a) Lateral conjugation (b) Fragmentation
	(a) Two similar motile gametes	10	(c) Palmella stage (d) Scalariform conjugation
	(b) Two similar non-motile gametes but physiological	18.	In Spirogyra sometimes the gametes behave directly as
	dissimilar		zygospores without fusion. Such reproductive bodies are called [AIIMS 1992]
	(c) One motile and one non-motile gametes		called [AIIMS 1992] (a) Azygospores (b) Hypnospores
1	(d) Two dissimilar motile gametes Spirogyra is a [CPMT 1996]		(c) Zygospores (d) Aplanospores
4.	(a) Fresh water and free floating alga	19.	The cell wall of Spirogyra is made up of [MP PMT 1996]
	(b) Marine and free floating alga	13.	(a) Cellulose (b) Pectin
	(c) Fresh water and locomotory alga		(c) Lignin (d) Chitin
	(d) None of the above	20.	Zoospores are absent in [Odisha JEE 2012]
5.	Zygospore of Spirogyra produces [CBSE PMT 1993]	20.	(a) Vaucheria (b) Spirogyra
J.	(a) 2 zoospores (b) 4 zoospores		(c) Cladophora (d) Chlamydomonas
	(c) 2–4 zoospores (d) None of the above	21.	
6.	On germination each zygospore of Spirogyra gives rise to		(a) The filaments showing scalariform conjugation are
0.	(a) Four plants (b) Three plants		homothallic
	(c) Two plants (d) One plant		(b) The filaments showing lateral conjugation are
7.	Pond silk' is the common name of [Kerala CET 2003]		homothallic
	(a) Ulothrix (b) Spirogyra		(c) The filaments showing lateral conjugation are
	(c) Vaucheria (d) Oedogonium		heterothallic
8.	In Ulothrix, sexual reproduction is by		(d) Asexual reproduction occurs by zoospores
	[Bihar PMT 1994; CBSE PMT 1997]	22.	Which one of the following is an example of chlorophyllous
	(a) Isogamy (b) Anisogamy		thallophyte [KCET 2011]
	(c) Oogamy (d) Conjugation		(a) Volvariella (b) Spirogyra
9.	In Spirogyra lateral conjugation takes place in the cells of		(c) Nephrolepis (d) Gnetum
	[Odisha JEE 2010]	23.	Which is correct statement for <i>Ulothrix</i> [CBSE PMT 1998]
	(a) Same filament	20.	(a) Filamentous alga with flagellated reproductive stages
	(b) Two filaments of same species		(b) Filamentous alga with nonflagellated reproductive stages
	(c) Two filaments of different species		(c) Membranous alga producing zoospores
	(d) Both (a) and (b)		(d) Nonmotile colonial alga lacking reproductive stages
10.		24.	A cell of <i>Ulothrix</i> has chloroplasts [RPMT 1995, 96]
	many haploid nuclei take part [Bihar MDAT 1995;	~	(a) 1 (b) 2
	CPMT 2001; AIIMS 2001]		(c) 3 (d) 4
	(a) One (b) Two	25.	Pigments present in <i>Ulothrix</i> are [RPMT 2002]
	(c) Three (d) All four		(a) Chl. a, Chl b and phycocyanin
11.	Sexual reproduction in which cells of two different Spirogyra filaments conjugate is known as [KCET 1998; CPMT 1999]		(b) Chl. a, Chl c, phycocyanin and fucoxanthin
	(a) Lateral conjugation (b) Scalariform conjugation		(c) Chl. a, Chl b, carotenes and xanthophylls
	(c) Parthenocarpy (d) Azygospory		(d) Chl. a and fucoxanthin
12.	The product of conjugation of <i>Spirogyra</i> is called	00	
12.	[CBSE PMT 2000; CPMT 2000]	26.	
	(a) Zoospore (b) Akinete		(a) Ulothrix (b) Spirogyra
	(c) Chlamydospore (d) Zygospore	07	(c) Saprolegnia (d) Chlamydomonas
13.		27.	Cells of Ulothrix are
	(a) Pyrenoid (b) Branched filament		(a) Round (b) Spherical
14.	(c) Discoid chloroplast (d) Rhizoidal branches	00	(c) Cylindrical (d) Rectangular
14.	The sexual reproduction in <i>Spirogyra</i> is (a) Oogamous (b) Anisogamous	28.	
	(c) Cleistogamous (d) None of the above		(a) Uninucleate gametangia (b) Multicellular gametes
15.	Sexual reproduction in Spirogyra can be described as	00	(c) Anisogamete (d) Sexual reproduction
	[MP PMT 1995, 98, 2001; BHU 2002]	29.	
	(a) Morphological anisogamy and physiological isogamy		CPMT 1995; MHCET 2001; MP PMT 2002; AIIMS 2004]
	(b) Morphological as well as physiological isogamy		(a) Zoospore formation (b) Gamete formation
	(c) Morphological as well as physiological anisogamy		(c) Zygote germination (d) Zoospore germination
5275	(d) Morphological isogamy and physiological anisogamy	30.	The chloroplast in Spirogyra is
16.	When three Spirogyra filaments are participating in		[Kashmir MEE 1995; BVP 2003]
	conjugation, the possibilities are that		(a) Spiral band shaped and wavy margin
	(a) The middle one may be female and outer ones are male		(b) Cup shaped and smooth margin
	(b) The middle one may be male and outer ones are female		
	(c) Both (a) and (b)		(c) Star shaped and wavy margin
	(d) None of the above		(d) Girdle shaped and smooth margin

			(a) Swimming antherozoids	
	(c) Holdfast (d) Zoogonidium Number of flagella present in the gametes of <i>Ulothrix</i> is		(b) An independent gametophyte	
	(a) Four (b) Three		(c) Archegonia	
	(c) One (d) Two		(d) Lack of vaccinate tions	

Observe the diagrams (A - D) given below and select the right option in which all the four items A - D are correctly [NCERT; CBSE PMT (Mains) 2011] identified

	A	В	C	D
(a)	Antheridia	Archegonia	Gemma cup	Sphagnum
(b)	Archegonia	Antheridia	Gemma cup	Sphagnum
(c)	Archegoni o-phore	Gemma cup	Gametophyte	Sphagnum
(d)	Gemma cup	Archegonio- phore	Sporophyte	Sphagnum

Elaters are present in sporogonium of

[CMC Vellore 1993; AIIMS 2002]

- (a) Riccia
- (b) Marchantia
- (c) Selaginella
- (d) Sphagnum
- Gametophytic generation is dominant in 15.

[NCERT; RPMT 1995; CPMT 1998;

Pb. PMT 2000; KCET 2001, 11; Odisha JEE 2005]

- (a) Pteridophyta (Pteris)
- (b) Bryophyta (Riccia)
- (c) Angiosperms (Rose)
- (d) Gymnosperms (Pinus)
- 16. First land inhabiting plants are

[CBSE PMT 1993; MP PMT 2004]

- (a) Angiosperms
- (b) Gymnosperms
- (c) Bryophytes
- (d) Pteridophytes
- One of the following is of considerable economic [CBSE PMT 1993] importance
 - (a) Riccia
- (b) Funaria
- (c) Marchantia
- (d) Sphagnum
- 18. Bryophytes can be separated from algae, because they
 - [CBSE PMT 1997, 99]
 - (a) Are thalloid forms
 - (b) Have no conducting tissue
 - (c) Possess archegonia
 - (d) Contain chloroplast

Compared with the gametophytes of the bryophytes the 19. gametophytes of vascular plants tend to be

[CBSE PMT (Pre.) 2011]

- (a) Smaller and to have smaller sex organs
- (b) Smaller but to have larger sex organs
- (c) Larger but to have smaller sex organs
- (d) Larger and to have larger sex organs
- Bryophytes resemble algae in the following aspects 20.

[KCET 2009]

- (a) Filamentous body, presence of vascular tissues and autotrophic nutrition
- Differentiation of plant body into root, stem and leaves and autotrophic nutrition
- (c) Thallus like plant body, presence of root and autotrophic nutrition
- (d) Thallus-like plant body, lack of vascular tissues and autotrophic nutrition
- [CBSE PMT (Pre.) 2011] 21. Archegoniophore is present in
 - (a) Funaria
- (b) Marchantia
- (c) Chara
- (d) Adiantum
- The evidence for aquatic origin of bryophytes is

[CPMT 1995, 2000; KCET 2000]

- (a) Ciliated sperms
- (b) Green colour
- (c) Protonema thread
- (d) Some are still aquatic
- Saprophytic bryophyte is
- [MP PMT 2003]
- (a) Buxbaumia aphylla
- (b) Ricciocarpus natans
- (c) Riccia fluitans
- (d) Radula sp
- Sporophyte dependent upon gametophyte is found in
 - [BHU 1995]

- (a) Algae
- (b) Fungi
- (c) Bryophytes
- (d) Pteridophytes
- Which place in India is called "The Golden Mine of [Kerala CET 2003] Liverworts"
 - (a) Eastern Himalayas
- (b) Western Himalayas
- (c) Western Ghats
- (d) Eastern Ghats
- Bryophytes comprise
- [CBSE PMT 1999; MP PMT 2013]
 - (a) Sporophyte is of longer duration
 - (b) Dominant phase of sporophyte which is parasitic
 - (c) Dominant phase of gametophyte which produces spores
 - (d) Small sporophyte phase and generally parasitic on gametophyte
- Which of the following is true about bryophytes 27.

[CBSE PMT 1999; BHU 2004]

- (a) They possess archegonia (b) They contain chloroplast
- (c) They are thalloid
- (d) All of these
- Dichotomous branching is found in 28.
 - [CBSE PMT 1999]
 - (a) Fern (c) Liverworts
- (b) Funaria (d) Polytrichum
- Bryophytes are dependent on water because

[CBSE PMT 1998; BHU 2012]

- (a) Archegonium has to remain filled with water for fertilization
- (b) Water is essential for fertilization for their homosporous nature
- (c) Water is essential for their vegetative propagation
- (d) The sperms can easily reach upto egg in the archegonium

	etrahedral	9.	Consider the following four staten	nents whether they are
	obilateral		correct or wrong	
Which of the following is a character wood	[MP PMT 2010, 12]		(A) The sporophyte in liverworts is in mosses	more elaborate than tha
	ing porous		(B) Salvinia is heterosporous	
7//1	on-porous		(C) The life-cycle in all seed-bearing	The state of the s
Which of the following is not the feat[B]	ure of gymnosperms BHU 2005; CPMT 2009]		(D) In Pinus male and female cone trees	
(a) Parallel venation			The two wrong statements together a	
(b) Perennial plants			27	CBSE PMT (Mains) 2011
(c) Distinct branches (long and shor	t branches)		(a) Statements (B) and (C) (b) S	tatements (A) and (B)
(d) Xylem with vessels			(c) Statements (A) and (D) (d) S	tatements (A) and (D)
27. In gymnosperms how many male ga	ametes are produced by	10.	The male cone of Pinus is modified	
each pollen grain	[HP PMT 2005]		(a) Long shoot (b) N	leedle leaves
(a) 4 (b) 3			(c) Dwarf shoot (d) N	lone of the above
(c) 2 (d) 1		11.	Which of the following structures in I	
28. A typical gymnospermous plant has	0 1	500000		R 1993; MP PMT 2002
cells. What will be number of chromo	o chromosomes in leaf			
gametophyte			(a) Megaspore, integument, root	
(a) 16 (b) 8			(a) Megaspore, integument, root(b) Endosperm, megaspore, pollen	grain
(c) 4 (d) 24	osomes in the cells of its			grain

■			Plant Kingdom 161 UNIVERSAL BOOK DEPOT 1960
12.	Pine wood consists of almost entirely	25.	Pinus produces [CMC Vellore 1994; CPMT 1995]
	(a) Tracheids		(a) No seeds (b) Flowers
	(b) Vessels		(c) No vascular tissues (d) Naked seeds in cones
	(c) Equal number of tracheids and vessels	26.	In Pinus, the spur (dwarf shoot) has [MP PMT 1993]
	(d) More vessels and less tracheids		(a) One needle (b) Two needles
13.	Winged seeds are found in [CMC Vellore 1993;		(c) Three needles (d) All correct
	CPMT 1995; BVP 2002; MP PMT 2004, 12]	27.	The secondary wood of Pinus is characterised by
	(a) Cycas (b) Pinus		[MP PMT 1993]
	(c) Papaver species (d) None of the above		(a) Presence of resin cells (b) Presence of resin ducts
14.	In Pinus seeds there are		(c) Absence of resin ducts (d) Presence of vessels
	(a) Two cotyledons (b) One cotyledon	28.	and the following differentiatives represents the
	(c) Fleshy cotyledons (d) Many cotyledons		gametophytic phase in <i>Pinus</i> [MP PMT 1994] (a) <i>Pinus</i> plant (b) Zygote
15.	Male prothallus (gametophyte) in Pinus is having		
	(a) 1 prothallial cell (b) 2 prothallial cells	29.	
	(c) 4 prothallial cells (d) A mass of cells	23.	
16.	Which of the following tissue is present in the leaves of Pinus		(a) Male gametophyte (b) Female gametophyte
10.	and serve to conduct water and food [CBSE PMT 1998;	20	(c) Sporophyte (d) None of the above
		30.	The gametophyte is not an independent, free-living
	CPMT 1999, 2001; AFMC 2002; Manipal 2005]		generation in
	(a) Xylem (b) Phloem		[CBSE PMT (Pre.) 2011; AIPMT (Cancelled) 2015] (a) Pinus (b) Polytrichum
3000	(c) Transfusion tissue (d) Conducting tissue		(c) Adiantum (d) Marchantia
17.	In the embryo of Pinus rosette cells lie	31.	
	(a) Above suspensor cells	011	The wing in <i>Pinus</i> seed originates from [MP PMT 1993] (a) Integument
	(b) Between suspensor and embryonal cells		(b) Adaxial surface of ovuliferous scale
	(c) Between primary and secondary suspensor cells		(c) Bract scale
	(d) Between embryonal and apical cells		(d) Cone axis
18.	Resin and turpentine are obtained from [NCERT]	32.	Seed of Pinus shows three generations as
	(a) Cycas (b) Pinus		[J & K CET 2002]
	(c) Abies (d) Cedrus		(a) Parent sporophyte, gametophyte and future sporophyte
19.	The winged pollen grain of Pinus sp. are produced in		(b) Parent gametophyte, sporophyte and future
	[MP PMT 1997, 2004; BVP 2002]		gametophyte
	(a) Pollen chamber (b) Anther		(c) Parent sporophyte, sporophyte, future gametophyte
	(c) Tapetum (d) Microsporangium	00	(d) None of these
20.	Of the following, the false character with respect to Pinus is	33.	In Pinus male gametes are produced in the pollen tube by
	(a) Bract and ovuliferous scales		the division of which of the following cells (a) Body cell (b) Stalk cell
	(b) Embryo with two cotyledons		(c) Tube cell (d) Prothallial cell
	(c) Resin canals in needles	34.	
	(d) Tracheids with bordered pits		The seed of <i>Pinus</i> sp. is [MP PMT 1997] (a) Uneconomic and nonendospermic
21.	Cataphylls are		(b) Abaxial and rounded
	(a) Leaves of Selaginella (b) Scaly leaves of Pinus		(c) Adaxial and endospermic
	(c) Needles of Pinus (d) Foliar leaves of Pinus		(d) Hypogeal and monocotyledonous
22.	Male gametophyte (mature pollen grain) of <i>Pinus</i> is found to be	35.	In Pinus male and female reproductive structures occur
	(a) 10 celled (b) 6 celled		[MP PMT 1996]
	(c) 4 celled (d) 2 celled		(a) On different branches of the same plant
23.	The wood of pinus is [MP PMT 2000, 12; AMU (Med.) 2006]		(b) On different plants
	(a) Pycnoxylic and monoxylic		(c) On same branch
	(b) Pycnoxylic and heteroxylous		(d) None of these
	(c) Manoxylic and homoxylous	36.	The pollination in Pinus is [AFMC 1995]
	(d) Manoxylic and heteroxylous		(a) Entomophilous (b) Anemophilous
24.	Which statement is correct with reference to Pinus	SEAW.	(c) Hydrophilous (d) Malscophilous
	(a) It is of much economic value	37.	In Pinus only lower part of oospore is concerned with the
	(b) It is cosmopolitan in distribution		development of embryo, such development is
	(c) If grows in deserts and exhibits xerophytic character		[CBSE PMT 1993]
	(d) If form deciduous trees in temperate region		(a) Meroblastic (b) Periblastic
			(c) Mesoblastic (d) None of these

DOOK	162 Plant Kingdom					
38.	Female cone of Pinus is considered equivalent to [MP PMT 2009]	10.	(a) Persistent cambium			
	(a) Dwarf shoot (b) Long shoot		(b) Short lived cambium			
	(c) Needles (d) Scale leaves		(c) Number of cambia produced in succession			
39.	Siphonogamous fertilization takes place in		(d) Isolated strips of cambium			
	(a) Bryophytes (b) Selaginella	11.	Which one of the following is a living fossil			
	(c) Fern (d) Pinus		[CBSE PMT 2004]			
40.	Pinus shows [CBSE PMT 2001; BHU 2006]		(a) Saccharomyces (b) Spirogyra			
	(a) Simple polyembryony		(c) Cycas (d) Moss			
	(b) Cleavage polyembryony	12.	Top-shaped multiciliate male gametes, and the mature seed			
	(c) Both simple and cleavage polyembryony		which bears only one embryo with two cotyledons, are characteristic features of [CBSE PMT 2005]			
	(d) None of the above		(a) Polypetalous angiosperms			
41.	A microsporophyll in Pinus has		(b) Gamopetalous angiosperms			
	[Pune CET 1998; Kerala PMT 2004]		(c) Conifers			
	(a) One microsporangium on the adaxial side		(d) Cycads			
	(b) One microsporangium on the abaxial side	10				
	(c) Two microsporangia on the abaxial side	13.	Negatively geotropic roots are found in [Odisha JEE 2005] (a) Colocasia (b) Cycas			
	(d) Two microsporangia on the adaxial side		n to be an experience (next a control to the first of the			
	(e) Four microsporangia on the lower side	1.4				
	Cycas	14.	Spermatozoid of Cycas is [APMEE 1995; JIPMER 2000]			
10000	PRODUCTION OF THE PROPERTY OF					
1.	Diploxylic or polyxylic vascular bundles are found in		(a) Biflagellate (b) Nonflagellate			
	(a) Pinus (b) Dryopteris		(c) Uniflagellate (d) Multiciliated			
-	(c) Cycas (d) Funaria	15.	Which is not a characteristic feature of Cycas			
2.	In which plant largest sperms (antherozoids) are found		(a) Naked ovules (b) Circinate vernation			
	[CBSE PMT 1998; CPMT 1998; MHCET 2000; BHU 2012]	16.	(c) Vessels (d) Girdling leaf traces Cycas has the largest			
	(a) Cycas (b) Pinus	10.	(a) Ovule (b) Egg			
	(c) Mango (d) Sunflower		(c) Sperm (d) All of these			
3.	Fern character in Cycas is [AFMC 2001]	17.	Cycas is			
	(a) Coralloid roots (b) Tap root system		(a) Hermaphrodite (b) Dioecious			
	(c) Circinate venation (d) Reticulate venation		(c) Monoecious (d) None of these			
4.	Coralloid roots of Cycas are useful in	18.	Cycas revoluta is [Pb. PMT 1997; Chd. CET 1999;			
	[MHCET 2004; BHU 2005]		CPMT 2002, 10; RPMT 2005]			
	(a) N_2 -fixation (b) Absorption of water		(a) Date Palm (b) Sea Palm			
	(c) Transpiration (d) Fixation	10	(c) Royal Palm (d) Sago Palm			
5.	Cycas circinalis is a source of [BVP 2004; CPMT 2005]	19.	Wood of Cycas is [APMEE 1996; Wardha 2002; DPMT 2004]			
	(a) Resin (b) Timber		(a) Monoxylic and manoxylic			
	(c) Essential oil (d) Starch (Sago)		(b) Manoxylic and polyxylic			
6.	The stem of female Cycas plant is a [MHCET 2002]		(c) Diploxylic			
	(a) Monopodium (b) Sympodium		(d) Monoxylic			
	(c) Rhizomatous (d) Dichotomous	20.	Cycas contains			
7.	Sterile part of Cycas microsporophyll is [MHCET 2004]	20.	(a) Mucilage ducts (b) Laticiferous vessels			
	(a) Apophysis (b) Sporophore		(c) Resin ducts (d) Oil ducts			
	(c) Middle part (d) Lower part	21.	In Cycas, pollination is by [DPMT 1999]			
8.	Polyembryony seen in Cycas is	- 551	(a) Wind (b) Insect			
	(a) Potential true polyembryony		(c) Water (d) Both (a) and (b)			
	(b) Potential true polyembryony and cleavage polyembryony	22.	In Cycas, the ovules are attached to megasporophyll			
	(c) Adventive polyembryony		(a) Laterally (b) Dorsally			
	(d) All of these		(c) Ventrally (d) Apically			
9.	Cycas leaflets are [MHCET 2004]	23.				
	(a) Sessile, straight, oval		(a) Circinate vernation in leaves			
	(b) Sessile, straight, linear-lanceolate		(b) Vessels			
	(c) Sessile, straight, spiny		(c) Motile sperms			
	(d) Sessile, smooth, twisted		(d) Ovules			

Plant Kingdom 163 UNIVERSAL

10.3			ROOK DEPOT 1960
24.	Cycas is living fossil as it has [BHU 1992] (a) Ciliated sperms	37.	,
	(b) Structure like that of Tree Fern		[AFMC 2001; Odisha JEE 2012
	(c) Restricted occurrence in certain areas		(a) Circinate ptyxis (b) Sori in microsporophyll
	(d) Been found in fossil state also		
25.			(c) Uniflagellated male gamete
23.	In Cycas, the endosperm is	20	(d) Both (a) and (b)
	(a) Sporophytic structure (b) Gametophytic structure	38.	
00	(c) New structure (d) Formed after fertilization		(a) Seeds (b) Motile Sperms
26.	Male gametes of cycads are [CPMT 1992]		(a) and opening
	(a) Rounded and nonciliate	39.	(c) Cambium (d) Vessels Ptyxis in Cycas is
	(b) Sickle – shaped biflagellate	37.	
	(c) Boat – shaped nonciliate		(a) Simple (b) Circular (c) Circinate (d) None of these
	(d) Large, top-like, spirally twisted with cilia	40.	Early embryogeny in <i>Cycas</i> is characterized by
27.	Coralloid roots of Cycas possess a symbiotic alga	10.	(a) Absence of suspensor cell
	[CPMT 1993; Bihar PMT 1996; BHU 1998; Pb. PMT 1999]		(b) Presence of expanded free nuclear division
	(a) Aulosira (b) Spirogyra		(c) Reduced free nuclear division
	(c) Ulothrix (d) Anabaena		(d) Many cotyledons
28.	Select one of the following pairs of important features	41.	
	distinguishing Gnetum from Cycas and Pinus and showing	41.	Identify the pair that exhibit circinate vernation [KCET 2010 (a) Psilotum and Riccia
	affinities with angiosperms [CBSE PMT 2008]		
	(a) Perianth and two integuments		(b) Equisetum and Selaginella
	(b) Embryo development and apical meristem		(c) Nephrolepis and Cycas
	(c) Absence of resin duct and leaf venation	40	(d) Riccia and Nephrolepis
	(d) Presence of vessel elements and absence of archegonia	42.	Which of the following taxa shows zooidogamous oogamy
29.	In Cycas Pollination takes place in		(I) Spirogyra (II) Funaria
	[CPMT 1990, 93; BHU 2005, 12; Odisha JEE 2010]		(III) Pteris (IV) Cycas
	(a) 3-celled stage (b) 4-celled stage		The correct answer is [EAMCET 2009
	(c) 2-celled stage (d) 1-celled stage		(a) I, II, III (b) I, III, IV
30.	Sago of Cycas is given to patients with stomach disorders	49	(c) I, II, IV (d) II, III, IV
	because it is [AIIMS 1997]	43.	Algal zone is characteristic of [CPMT 1994]
	(a) Cheap		(a) Normal root of Cycas (b) Root of Pinus
	(b) Easily digestible with less starch		(c) Coralloid roots of Cycas (d) Stem of Cycas
	(c) Tastier	particular.	Angiosperm
	(d) With high nutritive value	1.	Seed are found in [MP PMT 2005; AMU (Med.) 2006]
31.	Which is incorrect about Cycas [CBSE PMT 1998]		(a) Angiosperm (b) Bryophyta
	(a) Its xylem has vessels		(c) Pteridophyta (d) Algae
	(b) It has circinate venation	2.	Which of the following contain xylem vessel [AFMC 1996;
		-	J & K CET 2002; Haryana PMT 2005; MP PMT 2005]
	(c) It does not have well organised female flower		
20	(d) Its roots possess some blue–green algae		
32.	Vegetative reproduction in Cycas occurs by [RPMT 1998]	3.	
	(a) Scale leaves (b) Sporophylls	3.	Vessels and Companion cells are characteristics of
Land I	(c) Bulbils (d) Fragmentation		[BCECE 2005; MP PMT 2005, 07]
33.	Megasporophyll of Cycas is homologous to [AIIMS 2002]		(a) Angiosperm (b) Gymnosperm
	(a) Carpel (b) Stamen		(c) Pteridophyta (d) Fern
	(c) Petal (d) Sepal	4.	The stele found in monocot is [DPMT 2004]
34.	Cycas has two cotyledons but it is not included under		(a) Haplostele (b) Atactostele
	angiosperms because it has [CBSE PMT 2001]		(c) Dictyostele (d) Actinostele
	(a) Circinate ptyxis (b) Compound leaves	5.	Tap roots are commonly found in
	(c) Monocot like stem (d) Naked seeds		(a) Gymnosperms (b) Angiosperms
35.	Diploxylic condition occurs in Cycas in [APMEE 2002]	210	(c) Dicots (d) Monocots
	(a) Root (b) Stem	6.	Which of the following is/are grouped under phanerogams
	(c) Coralloid root (d) Leaflet		[BHU 2004]
36.	Microsporangia of Cycas occur over microsporophyll		(a) Angiosperms (b) Gymnosperms
	[AIIMS 1996; RPMT 2000]	95 0	(c) Pteridophytes (d) Both (a) and (b)
	(a) Adaxially (b) Abaxially	7.	Which is not a monocot [BHU 2005]
			(a) Rose (b) Orchids
	(c) Laterally (d) Marginally		(c) Palms (d) Banana

BOOK	DEPOT 1960		
8.	Which of the following is a saprophytic angiosperm	5.	Plants of this group are diploid and well adapted to extreme
	[MHCET 2001]	85 0 8	conditions. They grow bearing sporophylls in compact
	(a) Cuscuta (b) Neottia		structures called cones. The group in reference is [NCERT
9.	(c) Agaricus (d) Mango		(a) Monocots (b) Dicots
9.	An angiosperm is different from a gymnosperm in the absense of		(c) Pteridophytes (d) Gymnosperms
	(a) Vascular tissue (b) Ovary	6.	If the diploid number of a flowering plant is 36. What would
	(c) Seed (d) Naked ovule	o.	be the chromosome number in its endosperm
10.	Which of the following is considered as more evolved		[NCERT
	(a) Dicot plant (b) Monocot plant		(a) 36 (b) 18
	(c) Data are incomplete (d) Both (a) and (b)		(c) 54 (d) 72
11.	In which of the following secondary growth takes place	7.	Protonema is [NCERT
	[MP PMT 2001] (a) Riccia (b) Funaria		(a) Haploid and is found in mosses
	(c) Selaginella (d) None of these		(b) Diploid and is found in liverworts
12.	An angiosperm differs from a gymnosperm by possessing		(c) Diploid and is found in pteridophytes
	[MHCET 2002]		(d) Haploid and is found in pteridophytes
	(a) Ovule (b) Xylem vessels	8.	The giant Redwood tree (Sequoia sempervirens) is a/an
	(c) Xylem tracheids (d) Seed	٥.	[NCERT
13.	Largest flower Rafflesia is [RPMT 1995; CPMT 1998]		(a) Angiosperm (b) Free fern
	(a) Total stem parasite (b) Total root parasite		(c) Pteridophyte (d) Gymnosperm
14.	(c) Partial stem parasite (d) Partial root parasite Which of the following is the tallest tree of the world		(c) Floridophiyio (d) Cymhlospeini
1.4.	[HP PMT 2005; AMU (Med.) 2006]	-	Critical Thinking
	(a) Eucalyptus regnans (b) Sequoia sempervirens		Critical Thinking
	(c) Pinus logifolia (d) Pinus roxburgii	-	
15.	Male gametophyte with least number of cells is present in	100000000000000000000000000000000000000	Objective Questions
	[CBSE PMT 2014]	1.	Which one of the following is commonly called a
	(a) Lilium (b) Pinus (c) Pteris (d) Funaria		"Maidenhair fern" [Kerala PMT 2006
16.	In majority of angiosperms [NEET (Phase-II) 2016]		(a) Pteridium (b) Adiantum
10.	(a) A small central cell is present in the embryo sac		(c) Dryopteris (d) Pteris
	(b) Egg has a filiform apparatus	2.	Pinus seed is originated in [MP PMT 2003]
	(c) There are numerous antipodal cells		(a) Capsule (b) Microsporophyll
	(d) Reduction division occurs in the megaspore mother	20	(c) Microsporangia (d) Megasporophyll
	cells	3.	In which one of the following male and female
-			gametophytes do not have free living independent existence [CBSE PMT 2008]
	NCERT		(a) Polytrichum (b) Cedrus
			(c) Pteris (d) Funaria
	Exemplar Questions	4.	Consider the following statements with respect to
			gymnosperms and angiosperms
1.	Fusion of two gametes which are dissimilar in size is termed		A. Double fertilization is an event unique to gymnosperms
	as [NCERT] (a) Oogamy (b) Isogamy		B. Angiosperms range in size from microscopic, Wolfia to
	(c) Anisogamy (d) Zoogamy		tall trees of Sequoia
2.	Holdfast, stipe and frond constitutes the plant body in case		C. In gymnosperms the seeds are not covered
	of [NCERT]		D. In gymnosperms the male and female gametophytes
	(a) Rhodophyceae (b) Chlorophyceae (c) Phaeophyceae (d) All of the above		have an independent free living existence
3.	A plant shows thallus level of organization. It shows rhizoids		Of the above statements [Kerala PMT 2012]
Tell 9	and is haploid. It needs water to complete its life cycle		(a) A and B alone are correct
	because the male gametes are motile. Identify the group to		(b) C alone is correct
	which it belongs to [NCERT]		
	(a) Pteridophytes (b) Gymnosperms (c) Monocots (d) Bryophytes		(c) B and C alone are correct
4.	A Prothallus is [NCERT]		(d) C and D alone are correct
	(a) A structure in pteridophytes formed before the thallus	2201	(e) D alone is correct
	develops	5.	Two type of cells hyaline and green or with various shades
	(b) A sporophytic free living structure formed in		are characteristic of bryophytes in
	pteridophytes (c) A gametophyte free living structure formed in		(a) Funaria hygrometrica
	pteridophytes		(b) Polytrichum commune
	(d) A primitive structure formed after fertilization in		(c) Sphagnum pappiolossum
	pteridophytes		(d) Porella pelatyphylla

UNIVERSAL

- When the sperms of Funaria and Pteris are put together near the archegonia of Pteris, only the sperms of Pteris readily enter the archegonia and reach the egg. The reason being that [CBSE PMT 1994]
 - (a) Sperms of Funaria are killed when mixed with sperms
 - (b) Archegonia of Pteris secrete a substance with repels sperms of Funaria
 - (c) Archegonia of Pteris secrete a chemical substance which attracts sperms of Pteris chemotactically
 - (d) Sperms of Funaria are less motile

Match the following with correct combination 7.

	Column - I		Column - II
A.	Anthoceros	1.	Walking fern
B.	Adiantum	2.	Alga
C.	Sargassum	3.	Inferae
D.	Asterales	4.	Gametophyte
	The second second	5.	Hornwort
	STATE OF STA	6.	Liverwort

[Kerala PMT 2007]

- (a) A-6, B-5, C-1, D-3 (b) A-5, B-4, C-3, D-2
- (c) A-5, B-1, C-2, D-4 (d) A-3, B-2, C-1, D-5
- (e) A-1, B-4, C-3, D-5
- 8. Read the following five statements (A-E) and answer as asked next to them
 - (A) In Equisetum the female gametophyte is retained on the parent sporophyte
 - (B) In Ginkgo male gametophyte is not independent
 - (C) The sporophyte in Riccia is more developed than that in Polytrichum
 - (D) Sexual reproduction in Volvox is isogamous
 - (E) The spores of slime moulds lack cell walls

How many of the above statements are correct

[CBSE PMT (Mains) 2012]

- (a) Two
- (b) Three
- (c) Four
- (d) One
- The ferns in which the entire sporangium develops from a single superficial cell of the sporophyll are known as
 - (a) Leptosporangiate
- (b) Eusporangiate
- (c) Unisporangiate
- (d) Mesosporangiate
- 10. If the haploid number of chromosomes in Pinus is 12, the number in its endosperm cells will be

[BHU 1994; CPMT 1999; KCET 1999; MP PMT 2002]

- (a) 12
- (b) 24
- (c) 36

- (d) 6
- "Monkey's puzzle" is a common name for 11.
 - (a) Araucaria embricata
- (b) Cycas revolute
- (c) Pinus longifolia
- (d) Gnetum genon
- 12. The 13-celled male gametophyte of Selaginella shows

[CPMT 1999; BHU 2001,03; AIIMS 2001]

- (a) 8 cells of the antheridium + 5 prothallial cells
- (b) 9 cells of the antheridium + 4 prothallial cells
- (c) 10 cells of the antheridium + 3 prothallial cells
- (d) 8 jacket cell + 4 androgonial + 1 prothallial cells

- Which of the following alga shows heterotrichous habit
 - (a) Oedogonium
- (b) Chlamydomonas
- (c) Ulothrix
- (d) Stigeoclonium
- The number of antherozoids produced from an antheridium of Selaginella is
 - (a) 64

- (b) 256 and above
- (c) 25 to 50
- (d) 128 to 256
- Read the following five statements (A to E) and select the 15. option with all correct statements
 - (A) Mosses and Lichens are the first organisms to colonise a bare rock.
 - (B) Selaginella is a homosporous pteridophyte.
 - (C) Coralloid roots in Cycas have VAM.
 - (D) Main plant body in bryophytes is gametophytic, whereas in pteridophytes it is sporophytic.
 - (E) In Gymnosperms, male and female gametophytes are present within sporangia located on sporophyte.

[AIPMT (Cancelled) 2015]

- (a) (B), (C) and (D)
- (b) (A), (D) and (E)
- (c) (B), (C) and (E)
- (d) (A), (C) and (D)
- 16. The male cone of Pinus is formed of

[CPMT 2000; KCET 2000]

Or

- In Pinus, male cone bears a large number of [BHU 2006]
- (a) Anthers
- (b) Megasporophylls
- (c) Ligules (d) Microsporophylls
- 17. Of the following group which secrete and deposit calcium carbonate and appear like corals [Kerala CET 2003]
 - (a) Red algae
- (b) Brown algae
- (c) Blue green algae
- (d) All of these
- 18. The gametophytic generation in pteridophytes is commonly called [KCET 1999; AIIMS 1999]
 - (a) Thallus
- (b) Plant body
- (c) Prothallus
- (d) Protonema
- 19. Which one of the following pairs is wrongly matched [CBSE PMT (Mains) 2012]
 - (a) Ginkgo Archegonia
- (b) Salvinia Prothallus
- (c) Viroids RNA
- (d) Mustard Synergids
- A protective cap or hook like covering on the developing capsule in a moss or liverwort is known as (a) Spine
- (b) Calyptra
- (c) Lodicule
- (d) Calyptrogen
- 21. Number of cotyledons in Zea, Cycas and Pinus respectively [BHU 2000]
 - (a) 1,1, many
- (b) 1,2,1
- (c) 1.1.1
- (d) 1,2,many
- Which one of the following is common to multicellular fungi, filamentous algae and protonema of mosses

[CBSE PMT (Pre.) 2012]

- (a) Diplontic life cycle
- (b) Members of kingdom plantae
- (c) Mode of Nutrition
- (d) Multiplication by fragmentation
- A. Heterospory
 - B. Seed formation
 - C. Fertilization process

What is appropriate for gymnosperms

[RPMT 1997]

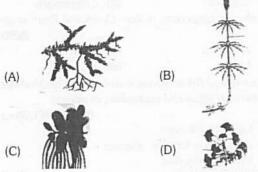

- (a) AB true C false
- (b) BC true A false
- (c) ABC all true
- (d) ABC all false

- Flagellated male gametes are present in all the three of [CBSE PMT 2007] which one of the following sets
 - (a) Anthoceros, Funaria and Spirogyra
 - (b) Zygnema, Saprolegnia and Hydrilla
 - (c) Fucus, Marsilea and Calotropis
 - (d) Riccia, Dryopteris and Cycas
- In Pinus, the approximate time for fertilization after 25. pollination is [Pune CET 1998]
 - (a) Only a few hours
- (b) Only a few days
- Only a few weeks
- (d) About one year
- Heteromorphic alternation of generations occurs is 26.
 - **[EAMCET 1995]**
 - (a) Funaria, Spirogyra, Selaginella
 - (b) Funaria, Selaginella, Cycas
 - (c) Spirogyra, Rhizopus, Selaginella
 - (d) Rhizopus, Funaria, Spirogyra
- 27. Make correct pair
 - Cyanophyceae
- Green colour
- B. Chlorophyceae
- Blue green colour b.
- Phaeophyceae C
- Red colour C.
- Rhodophyceae
- Brown colour d. [RPMT 1997]
- (a) Aa, Bb, Cc, Dd
- (b) Ab, Bc, Cd, Da
- (c) Ab, Ba, Cd, Dc
- (d) Ad, Bd, Ca, Db
- [CPMT 1993, 99; The endosperm of gymnosperm is 28. CBSE PMT 1999; RPMT 2006; Odisha JEE 2012]
 - (a) Triploid
- (b) Haploid
- (c) Diploid
- (d) Polyploid
- In which of the following, multiciliated/multiflagelated 29. [CPMT 1999; BHU 2003] antherozoids are present
 - (a) Riccia and Funaria
- (b) Pteris and Cycas
- (c) Riccia and Cycas
- (d) Marchantia and Riccia
- When the gametophyte is not formed by spores but by any 30. other part of sporophyte, it is known as [AIIMS 1998]
 - (a) Multispory
- (b) Polyspory
- (c) Apospory
- (d) Germination
- A mature ligule, having a prominent basal portion, is called 31. [AIIMS 1998; CPMT 2000; CBSE PMT 2002]

The basal portion of ligule of Selaginella is hemispherical and is called

- (a) Trichocyst
- (b) Heterocyst
- (c) Rhizophore
- (d) Glossopodium
- Examine the figures A, B, C and D. In which one of the four options all the items A, B, C and D are correct

Ontions

[CBSE PMT(Mains) 2010]

	A	В	С	D
(a)	Chara	Marchantia	Fucus	Pinus
(b)	Equisetum	Ginkgo	Selaginella	Lycopodium
(c)	Selaginella	Equisetum	Salvinia	Ginkgo
(d)	Funaria	Adiantum	Salvinia	Riccia

Match the columns

	Colum	ın-l		Column-II	
A.	Hornw	ort	1.	Lycopodium	
B.	Liverwort Stonewort		2.	Ricciocarpus	
C.			3.	Anthoceros	
D.	Club moss		4.	Chara	
					[AIIMS 2010]
	Α	В	C	D	
(a)	2	3	4	1	

(b) (c) 3 2 4 (d) 3 2 4 1

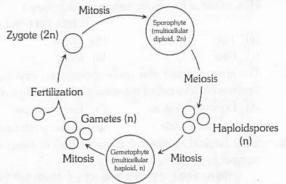

Which one of the following is a correct statement

[CBSE PMT (Pre.) 2012]

- (a) Pteridophyte gametophyte has a protonemal and leafy stage
- (b) In gymnosperms female gametophyte is free-living
- Antheridiophores and archegoniophores are present in pteridophytes
- (d) Origin of seed habit can be traced in pteridophytes
- Read the following statements (A E) and answer the 35. question which follows them
 - (A) In liverworts, mosses and ferns gametophytes are free living
 - (B) Gymnosperms and some ferns are heterosporous
 - (C) Sexual reproduction in Fucus, Volvox and Allbugo is
 - (D) The sporophyte in liverworts is more elaborate than that in mosses
 - (E) Both, Pinus and Marchantia are dioecious
 - How many of the above statements are correct [NEET 2013]
 - (a) Four Two

(c)

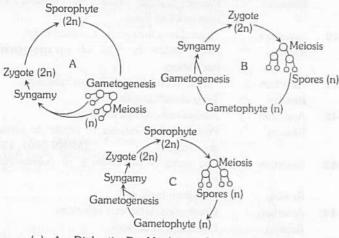

- (b) One (d) Three
- What is common in all the three Funaria, Dryopteris and 36. [NEET (Karnataka) 2013] Ginkgo
 - (a) Presence of archegonia (b) Well developed vascular tissues (c) Independent gametophyte (d) Independent sporophyte
- The given figure is showing life cycle of a plant if this belongs to life cycle of bryophytes, pteridophytes and gymnosperms, what will be respective A and B in their life [NCERT]

	A	В
(a)	Bryophytes : Pteridophytes : Gymnosperms :	Strobili, capsule cones, sporangia flowers, cones
(b)	Bryophytes : Pteridophytes : Gymnosperms :	Protonema, gametophores strobili, sporangia flowers, cones
(c)	Bryophytes : Pteridophytes : Gymnosperms :	Capsule, protonema (gametophores) sporangia, cones, sporophyll fertile fronds, megasporangia and microsporangia
(d)	Bryophytes : Pteridophytes : Gymnosperms :	Sporangium, capsule strobili, sporangia flowers, cones

38. Which of the following options are correctly represents the type of life cycle patterns given below [NCERT]

- (a) A Diplontic, B Haplontic, C Haplodiplontic
- (b) A Haplontic, B Diplontic, C Haplodiplontic
- (c) A Haplodiplontic, B Haplontic, C Diplontic
- (d) A Diplontic, B Haplodiplontic, C Haplontic
- 39. Select the correct statement [NEET (Phase-I) 2016]

 (a) Gymnosperms are both homosporous and heterosporous
 - (b) Salvinia, Ginkgo and Pinus all are gymnosperms
 - (c) Sequoia is one of the tallest trees
 - (d) The leaves of gymnosperms are not well adapted to extremes of climate
- In bryophytes and pteridophytes, transport of male gametes requires [NEET (Phase-I) 2016]
 - (a) Wind
- (b) Insects
- (c) Birds
- (d) Water
- 41. Select the mismatch
- [NEET 2017] Dioecious
- (a) Pinus –
 (b) Cycas –
- Dioecuous
- (c) Salvinia (d) Equisetum
- Heterosporous Homosporous
- 42. Life cycle of Ectocarpus and Fucus respectively are

[NEET 2017]

- (a) Haplontic, Diplontic
- (b) Diplontic, Haplodiplontic
- (c) Haplodiplontic, Diplontic (d) Haplodiplontic, Haplontic

R Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- 1. Assertion : Biennial plants flower in two year.

 Reason : The biennial plants live for two years.

- Assertion : Bryophytes and tracheophytes have an embryo stage in their life cycle.
 - Reason : Embryophyta are terrestrial plants.
- Assertion : Stamens are comparable to microsporophylls.
 Reason : Ovules are comparable to megasporophylls.
- Assertion : Algae and fungi are grouped in thallophyta.
 Reason : Algae and fungi show no differentiation in
 - thallus.
- Assertion : Each group of algae has a characteristic colour.
 - Reason : Each group of algae show predominance of one pigment.
- **6.** Assertion : Only red algae are able to flourish at the great depth of sea.
- Reason : Red algae has the pigments r-phycoerythrin and r-phycocyanin.
- Assertion : Spermatangium of red algae bears trichogyne.
 - Reason : Trichogyne helps in reproduction.

 Assertion : Spirogyra is slippery in touch.
- Reason : Spirogyra consists a gelatinous sheath.
- Assertion : Isogamy is a primitive type of sexual reproduction.
- Reason : The gametes are of different sizes.

 10. Assertion : Angiosperms lack flagellate male gametes.
- Reason : Sperms are not dependent on water for fertilization.
- 11. Assertion : Fertilized ovule forms seed. Reason : Ripened ovary forms fruit.
- **12.** Assertion : Pyrenoids are utilised during starvation. Reason : Pyrenoids are proteinaceous bodies.
- 13. Assertion : In green algae, the eye-spot is present in the cell.
 - Reason : Eye-spot is meant for respiration.
- **14.** Assertion : Chlorella could be utilised to keep the air pure in space vehicles.
- Reason : The space travelers feed on *Chlorella* soup.

 15. Assertion : Flower is aggregation of sporophylls.
- Reason : Sporophylls are modified in angiosperms.

 16. Assertion : Chlorella could serve as a potential source
 - of food and energy.

 Reason: When dried, chlorella has 15% protein, 45% fat, 10% carbohydrate, 20% fibre,
 - and 10% minerals and vitamins.

[AIIMS 2009]

- 17. Assertion : Spirogyra shows haplontic life cycle.Reason : Zygotic meiosis occurs in Spirogyra.
- 18. Assertion : Red algae contribute in producing coral reef.

 Reason : Some red algae secrete and deposit
 - calcium carbonate our their walls.
 - [AIIMS 2004]
- 19. Assertion : The sex organs in the bryophytes are jacketed.
- Reason : Bryophytes are land plants.

 20. Assertion : All bryophytes are land duelle.
 - Assertion : All bryophytes are land dwellers.

 Reason : Water is necessary to complete their life
 - cycle.

UNIVERSAL BOOK DEPOT 1960

168 Plant Kingdom

21.	Assertion	:	The bryophytes exist in two phases – gametophyte and sporophyte.	39.	Assertion	:	The mesophyll of <i>Pinus</i> shows no distinction as mesophyll and palisade.
	Reason	:	The sporophyte is nutritionally independent.		Reason	:	Parenchymatous cells are present in mesophyll of Pinus.
2.	Assertion	:	Unlike thallophytes, bryophytes show	40.	Assertion		Pinus shows formation of annual rings.
	Reason	:	formation of embryo. The embryo gives rise to gametophyte		Reason	:	Pinus grows in area of environmental fluctuation.
			plant of bryophytes.	41.	Assertion	:	Mosses are used as pollution indicators.
3.	Assertion		Bryophytes possess archegonium as a female sex organ.		Reason	:	They absorb metals.
	Reason		Algae also possess the archegonium.	42.	Assertion	:	Mosses are evolved from algae.
4.	Assertion		The embryo of bryophyte is independent.		Reason	:	Protonema of mosses is similar to some
.**.	Reason		The zygote of thallophyte is dependent.				green algae. [AIIMS 2001, 13
5.	Assertion	:	Liverworts fail to spread to a new locality through fragmentation.	43.	Assertion	:	The sorus of <i>pteridium</i> is of coenosorus type.
	Reason		Gemmae are helpful in propagating		Reason	:	Pteridium lacks sori.
			liverworts in different locality.	44.	Assertion	:	Coenosorus lacks true indusium.
26.	Assertion	:	Pinus displays the alternation of		Reason	:	Indusium covers sori.
			generations.	45.	Assertion	:	Ramenta are scales which cover young
	Reason		The gametophyte is dependent upon the		mile all		rhizome and leaves of Dryopteris.
27.	Assertion		sporophyte phase. Pinus embryo has two cotyledons.		Reason	:	Pteridium lacks rementa.
61.	Reason	1	Pinus shows polyembryony.	46.	Assertion	•	The scale leaves on the long shoots are
28.	Assertion		The female cones take much time to		D		called cataphylls. Cataphylls lack mid rib.
	11000111011		mature.	47.	Reason Assertion		Both bryophytes and pteridophytes contain
	Reason	:	The seeds are shed when the cone is 22 months old.	47.			well-developed antheridia.
29.	Assertion	:	The female cones are same in number as male cones.		Reason	:	Biflagellate sperms are formed by their antheridia.
	Reason	:	Male and female cones appears alternately on the same branch of the Pinus.	48.	Assertion	•	Water is not required for fertilization process in ferns.
30.	Assertion Reason	:	Sperms of <i>Riccia</i> are biflagellate. Sperms show swimming nature.		Reason	:	Malic acid of archegonial neck attract antherozoids.
31.	Assertion	:	The sporogonium of <i>Riccia</i> is the simplest among the liverworts.	49.	Assertion	:	Sporophytes of pteridophyta are dominar individual.
	Reason		Sporophyte consists of capsule only.		Reason	:	They do not show the formation of true
32.	Assertion		The young stem of Funaria is				root.
J			photosynthetic. It contain hydroids.	50.	Assertion	:	In gymnosperms, plants show well developed vessels and fibres.
33.	Reason Assertion		Pinus is monoecious.		Reason	:	Companion cells are absent in gymnosperm
J	Reason	;	Each sporophyll bears only one microsporangia.	51.	Assertion	i	In leptosporangiate development, sporangiare formed from a group of initials.
34.	Assertion	:	Funaria multiplied vegetatively by means of bulbils.		Reason	:	Eusporangiate development of sporangi starts from single initial.
	Reason	:	Bulbils and tubers are two different	52.	Assertion	:	Adiantum caudatum is called walking fern.
			structures.		Reason	:	It can reproduce by its leaf tips.
35.	Assertion	:	Gemmae formation in Funaria occurs in	53.	Assertion	:	Gymnosperms seeds are naked.
	Reason		favourable condition. The gemmae form on the stem and leaves.		Reason	:	They lack ovary wall.
36.	Assertion		Funaria is monoecious.	54.	Assertion	:	Pinus has a pyramidal appearance.
	Reason		Cross fertilization occurs in Funaria.		Reason	:	The older parts of long shoot have scars of
37.	Assertion		Antheridia of Funaria are sunk in pit.				fallen dwarf shoots.
٠,,	Reason		Its antheridial cluster is surrounded by	55.		:	The female cone of Cycas is not true cone.
	neason	•	perigonial leaves.		Reason	:	Its formation checks the growth of the stem
38.	Assertion	:	The peristome is a fringe of teeth-like	56.		:	All living species of Cycas are dioecious.
JO.	USSELIIOII	1000	projections found at the mouth of the		Reason	•	Cycas contains male and female cones of the same plant.
	Reason	:	capsule. It may be of two types nematodontous and	57.	Assertion	:	The male of Cycas change in size when th microspores became mature.
	4.		orthodontus.		Reason	:	The microspores are dispersed by wind.

Answers and Solutions

Algae (General)

- (a) M.O.P lyenger of Madras is regarded as the father of Indian phycology. He discovered Fritschiella, a heterotrichous terrestrial alga.
- (a) The study of algae is called algalogy or phycology (Gr. phykos = algae) and its expert as phycologist / algalogist.
- 3. (a) F.E. Fritsch (1935) divided algae into following eleven classes in his book "Structure and Reproduction of the Algae", mainly on the basis of pigmentation, reserve food and flagellation, thallus structure, modes of reproduction and life cycles and he is known as father of algae.
- 7. (d) Agar-agar is a jelly like substance. It is a nonnitrogenous carbohydrate consisting of two polysaccharides namely agarose and agaropectin. It is obtained from several red algae. e.g., Gracillaria, Gelidium, Gigartinia. It was discovered by Lady Hesse and used by Robert Koch to solidify culture medium.
- 15. (a) Different type of colour in Algae are due to different pigmentations and it provides a strong base to classify the Algae.
- (c) Cephaleuros virescens is a member of class chlorophyceae and cause disease red rust of tea leaf (Thea sinensis).

- 22. (b) Spirulina viridisma: It is a convoluted cyanophycian alga, which has 60% protein contents.
- **24.** (d) All are eukaryotes except Anabaena. The later is prokaryotes where true nucleus is absent.
- 28. (c) Many algae important constituent of human food in future because the algae can grow easily and obtained protein, lipid carbohydrates and vitamins. e.g., Chlorella, Ulva.
- 32. (b) Pyrenoids are the rounded bodies found in the chloroplast of green algae and are the centres of conversion of glucose to starch and also collection of starch.
- (c) Because algae and fungi are the members of thallophyta.
- **34.** (a) Chlorella vulgaris: This is the source of protein. This is rounded unicellular algae related to class chlorophyceae.
- 36. (c) Hypnospores are thick walled non-motile spores formed to tide over unfavourable condition. They germinate on the arrival of favourable condition ns. e.g., Chlamydomonas, Ulothrix.
- 38. (b) In dry conditions, zoospores get surrounded by mucilaginous sheath. This is known as Palmella stage. Under favourable conditions each zoospore gives rise to a new plant e.g., Chlamydomonas.
- **41.** (b) In Rhodophyceae reserve food products are polysaccharides *i.e.*, Floridean starch (which stains red with iodine solution) and also soluble sugar called floridoside.
- 43. (a) The larger (giant) parenchymatous forms of brown algae called kelps or sea weed or trees of seas or forest of sea. Sea weed may be marine.
- **44.** (c) Chlorella could be used to provide O_2 during space flight trips. The alga can reuse CO_2 during the process of photosynthesis and release O_2 for the use by Astronauts.
- (d) Alginic acid is a non sulphated phycocolloid extracted from middle lamella/cell walls of Laminaria, Lessonia, Fucus etc.
- 46. (a) Algae differ from bryophyta because in algae sex organs are usually non-jacketed and in bryophyta sex organs are jacketed with sterile jacket.
- 47. (a) Parasitic algae like Cephaleuros virescens (green alga) causes red rust of tea leaves and C.coffea attacks coffee leaves. It is red due to haematochrome.
- 51. (a) Laminaria kelp is the source of iodine.
- **52.** (d) Carragenin is obtained from chondrus. It is member of Rhodophyceae.
- **54.** (a) Stomata are originated with the origin of bryophytes (Amphibian group). Algae are primitive 'than bryophytes.
- **55.** (c) Chlorophyll a and b pigments are found in chlorophyceae.
- **57.** (d) Fusion of gametes results in the formation of zygote, which by secreting a thick wall acts as perennating spore (zygospore) and helps in perennation, dispersal and multiplication.

- 59. (d) These are pteridophytes.
- 61. (a) In algae reserve food material is mainly starch.
- 64. (c) A large amount of iodine is extracted from kelps (brown sea weeds) like Laminaria, Ecklonia etc.).
- 65. (b) Volvox hollow ball like colony with a fixed number of cells is called coenobium.
- 67. (d) Oogamy is most advanced type of reproduction in which male gamete is motile smaller and non food storing called antherozoid while female gamete is food storing, nonmotile larger called oogonium.
- 69. (c) Grana is absent in green algae.
- 76. (a) Nucule/oogonium/upper sex organ Globule/antheridium/lower sex organ.
- 77. (b) Anabaena Non flagellated male gamete
 Spirogyra Aplanogamy
 Polysiphonia Non motile spermatia
 Ectocarpus Pear shaped motile male gametes
- **78.** (c) Algin is obtained from brown algae and carrageenin from red algae

Spirogyra and Ulothrix

- (c) Spirogyra increases its body length because every cell of the filament is capable of growth division and self maintainance (every cell has nucleus).
- (b) Sexual reproduction in Spirogyra involves the fusion of two morphologically identical but physiologically dissimilar nonciliated gametes.
- 4. (a) Spirogyra is a free floating, filamentous, green, freshwater alga which is popularly called pond silk, hair of princess because its filaments are slimy to touch and shine in water.
- 5. (d) Zygospore under goes meiosis to form a new filament.
- (d) Because single zygospore produce four spores but three are diminished and remaining one develop into a new plant.
- 7. (b) Spirogyra gives silky feeling on touching.
- 10. (a) Zygospore undergoes zygotic meiosis and forms 4 haploid nuclei of these three degenerate. So one haploid nuclei take part and one new filament is formed.
- 11. (b) In scalariform conjugation, two filament come to lie parallel and appressed. Their opposite cells develop conjugation tube. The conjugation tube between the two filaments look like a ladder.
- (b) Sexual reproduction of Spirogyra is physiological anisogamous.
- 15. (d) Sexual reproduction in Spirogyra can be described as fusion of two morphologically identical, but physiologically dissimilar gametes.
- 16. (c) Rarely three filaments may take part in scalariform conjugation. Here the central filament shows relative sexuality and behave as male to one and female to other so that zygospore are formed in either central or lateral filaments.
- 18. (a) On failure in fusion of two gametes, both the gametes develop into azygospores. Under unfavorable condition, the filament of S.varians placed in sugar solution develop parthenospore or azygospore.

- 19. (a) Each cell of Spirogyra is surrounded by two layered cell wall. Its inner layer is made up of cellulose and outer layer is made up of pectose but quantity of cellulosic substances is high in comparison to pectose.
- 21. (b) The filament showing lateral conjugation are homothallic because both male and female gametes are found in same filament.
- (a) Filamentous alga with flagellated reproductive stage represented by gametes.
- 24. (a) Each cell contains a single chloroplast in Ulothrix.
- 25. (c) Ulothrix is green algae.
- (c) Ulothrix is unbranched filament, consisting of numerous cylindrical cells joined end to end.
- 28. (a) Mucor have multinucleate gametangia.
- 29. (c) Favourable conditions each zygote germinates to produce 4–16 meiospores (zoospores or aplanospores). The first division of diploid zygotic nucleus is meiosis. The meio-zoospores or meioaplanospores germinate to produce new filaments.
- 31. (b) Spirogyra shows isogamy with non-flagellated gametes.
- **32.** (b) Chloroplast contains few pyrenoids (1–3) for starch storage.
- **33.** (c) Iyenger (1958) reported direct lateral conjugation in *Spirogyra jogensis*.
- **34.** (a) *Ulothrix* is unbranched filament and attached to stone and submerged bodies (fixed floating).
- 35. (a) A spore of Spirogyra sp. after resting period (zygospore) is haploid because meiosis occurs in zygospore.
- **36.** (b) Plant body of *Spirogyra* is haploid but after gametic fusion, diploid zygospore is formed, thus zygotic meiosis takes place.
- 38. (a) Life cycle in Spirogyra is haplontic as dominant phase in life cycle is haploid (n) and diploid phase is represented by only zygospore and it undergoes meiosis.
- (d) Chloroplast in *Ulothrix* is girdle or ring shaped (*U.zonata*) or collar shaped.
- 40. (a) Ulothrix produces isogametes i.e., gametes are biflagellate and similar (size, shape) but different in nature.
- **41.** (d) Basal cell is nongreen but has nucleus and cytoplasm. Its presence show beginning of division of labour.
- 43. (d) The gametes are motile and biflagellate.

Bryophytes (General)

- (d) Newzealand genera of moss Dawsonia which measures 60 cms in height.
- **5.** (d) Venter is present in archegonia just above the egg.
- 7. (b) The vascular tissue (i.e., xylem and phloem) are completely absent water and nutrients enter the cell by diffusion. Sporangium produces spores by meiosis. The zygote develops to form an embryo which produces the sporophyte.
- (c) They are called pollution indicators. They prevent soil erosion by running water.
- (a) Species of sphagnum, a moss provides peat that have long been used as fuel.

- (d) Because club moss is pteridophyte while Reindeer moss and Irish moss are lichens.
- 12. (d) In Bryophytes vascular tissue (i.e., xylem and phloem) are completely absent. Water and nutrients enter in cell by diffusion when in pteridophytes vascular tissue consists of xylem (without true vessels) and phloem (without companion cells).
- 14. (b) The sporogonium of Marchantia is differentiated into foot, seta and capsule. Capsule contains elaters (2n). Elaters are diploid, spindle shaped hygroscopic elongated structures with 2 spiral bands.
- 15. (b) The main plant of Bryophyte is gametophyte.
- (c) Bryophyta are the most simple and primitive group of embryophyta. It includes app. 840 genera and 23,500 species.
- 17. (d) Sphagnum is used as fuel. Sphagnum has the capacity to retain water for long periods and as such is used to cover the plant roots during transportation. It is also used in seed beds because of its high water retention capacity.
- 18. (c) The female sex organ is archegonia. It is flask shaped structure distinguishable into a long neck and a globular swollen venter.
- (a) Gametophytes are reduced and few celled in all vascular plants.
- (b) Stalk bearing archegonial cluster at tip in Marchantia thallus.
- 22. (a) In bryophytes, water is essential for fertilization because antherozoids are flagellated or cilliary structure which represent the aquatic origin of bryophytes.
- **23.** (a) Saprophytic bryophytes are *Buxbaumia aphylla*. Which are nongreen growing on rotten wood.
- 24. (c) In bryophytes, gametophyte is dominant phase and sporophyte is developed on this phase which is partially depends for food on gametophyte.
- **25.** (b) Bryophyta grow in moist and shady places. More humid conditions are found in Western Himalayas.
- **26.** (d) In Bryophytes, sporophyte is never independent but it is parasitic over gametophytic plant either partially for water and mineral supply or wholly for organic food.
- 27. (d) Male sex organ is globular called antheridium and female sex organ is called archegonium which is flask shaped. These are look like green in colour because they contain chloroplast. True roots, stem and leaves absent in Bryophytes.
- **30.** (c) The main plant of bryophyta is gametophyte. Gametophytic stage is independent.
- 31. (b) Term Bryophyta was coined by Robert Braun in 1864 but he included algae, fungi, lichens and mosses under it.
- 33. (c) Female sex organ is called archegonium which is flask shaped with a tubular neck and a swollen venter.
- **34.** (d) Thallus of *Anthoceros* shows symbiotic association with a nitrogen fixing blue green alga. *i.e.*, *Nostoc*.
- 35. (c) Below neck canal cells, there is a venter canal cell and an egg cell (oosphere) in the venter. Egg cell behaves as nonmotile female gamete.

- 37. (a) The number of chromosomes of the second generation will be same because no reduction division take place.
- 40. (c) The chloroplast of Anthoceros contains a unique feature 'pyrenoid' made up of 25–30 discoid or spindle shaped bodies.
- **43.** (a) The archegonial venter forms a protective covering around the embryo called calyptra.

Funaria and Riccia

- (c) Stomata are primitive because guard cells are not found. Only stomatal pores are found.
- (c) Protonema: It is green, septate, filamentous algae like which is borne after the germination of moss haploid spores.
- (c) The sporophytic is parasitic over gametophyte. Thus there is heteromorphic or heterologous alternation of generations in Riccia. So life cycle in Riccia is diplohaplontic.
- (b) Funaria is attached to substratum by rhizoids are branched, multicellular, arise from base of axis and have oblique septa to increase.
- 7. (a) When the capsule approaches maturity the sporogenous cells cease to divide, separate from one another and they are known as spore mother cells. Each spore mother cell undergoes two successive divisions, first of which is meiotic and forms four spores with haploid number of the chromosomes.
- **8.** (b) Protonema is formed after germination of moss capsule spores.
- (c) Life cycle of Funaria is not completed without water because antherozoids swim across the film of water and antherozoid fuse with the single egg to produce zygote (2n).
- 10. (b) Autotrophic nutrition is a common feature to gametophytes and sporophytes of mosses and fern because chlorophyll containing cells found in both which are assimilatory in function.
- (b) Capsule wall is a diploid part of sporophyte, if protonema is develops from its cells, it must be diploid.
- 13. (c) Foot, seta and central sterile portion of theca is called columella found in Funaria. Elaters are absent in Funaria, Sphagnum, Polytrichum, Riccia, etc. They are the characteristic features of Marchantia, Pellia, Porella, etc.
- (a) Dispersal of spores take place due to hygroscopic nature of peristomial teeth.
- 15. (c) Annulus assists in dehiscence of capsule.
- 16. (d) The neck is several cells high and is made up of six vertical rows of cells. It contains six or more elongated uninucleate neck canal cells.
- 17. (b) Monoecious means both male and female sex organs are borne on the same plant body and autoecious means green photosynthetic.
- (a) In Funaria fully developed sporophyte (sporangium) is made of three regions, i.e., Basal foot, seta and capsule.
- 20. (b) The axis has a central conducting strand of slightly thick walled parenchymatous elongated dead cells called hadrom.

- 22. (b) Leafy gametophyte develop from buds produced on protonema and is made up of axis with spirally arranged leaves, leafy gametophyte bears male and female sex organs.
- **23.** (c) Apophysis is basal sterile portion of capsule in continuation with seta. In capsule of *Funaria* stomata present only in apophysis.
- **24.** (b) Peristome teeth: Total 32 in two rows 16+16, outer 16 are thick bigger in size while inner 16 are smaller and thin. Teeth help in dispersal of spore filled in sporangium of capsule of *Funaria*.
- 25. (c) In funaria sex organs develop at tip stem antheridia develop on male branch and archegonia on female branch.
- **26.** (b) The antherozoids in *Funaria* are anteriorly biflagellated coiled structures.
- (d) On the lower portion of leafy gametophore, there are present branched, multicellular rhizoids with oblique septa.
- 29. (c) In Funaria central sterile portion of theca is called columella.
- (c) Female sex organs (archegonia) are borne at the tip of female branch which is larger than male shoot.
- (d) In capsule of funaria stomata are present only in apophysis.
- 32. (a) An archegonium of Riccia has neck encloses 4–6 neck canal cells. Venter wall is single layered and encloses one venter canal cell and one egg cell (oosphere).
- (c) The lower surface of Riccia bears two type of unicellular rhizoids, smooth walled and tuberculate and help in fixation.
- **36.** (a) Gametophyte stage of *funaria* is haploid because the main plant body is gametophyte.
- **38.** (b) Sex organs are multicellular, jacketed and embedded in thallus on dorsal side.
- **40.** (c) In *Riccia* antherozoids may enter into the archegonium and fuse with single egg to form zygote (2n), which is ending of gametophyte phase.
- **41.** (b) Spore is the first cell of gametophytic generation In *Funaria* the spore germinates to form protonema.
- **43.** (c) The main plant body of *Riccia* is gametophytic (n), which is thallose, i.e., having no true roots, stem and leaves.
- **44.** (d) Meiosis takes place in spore mother cells which results four haploid spores are formed.
- 45. (b) The peristome is distinguishable into two whorls of radially arranged peristomial teeth.
- 46. (a) Protonema is the branched filamentous portion which is produced by germination of spores.

Pteridophytes (General)

 (b) Pteriodophytes are also known as "Vascular cryptogams'. The term 'Cryptogams' is made of 2 Greek word, i.e., Kryptose, hidden + gamous, wedded, i.e., these are the plants which reproduce by means of spores and do not produce seeds.

- (c) Birbal sahani was a famous Indian palaeobotanist. He established famous Birbal Sahani institute of paleobotany in Lucknow (UP) and described Williamsonia sewardiana.
- 5. (d) Due to protandrus (maturation of antheridia before Archegonia) condition archegonia of same thallus do not accept the antherozoids of same thallus. Therefore self fertilization is not possible in Pteridophytes or vascular cryptogames.
- 8. (b) The club mosses (division Lycophyta) are now limited to representatives a few centimeters in height. Their leaves are small and scale like, resembling the leaf like structures of mosses, club mosses of the genus Lycopodium, commonly known as ground pine, form a beautiful ground cover in some temperate coniferous and deciduous forests.
- (a) Gametophyte of fern is exosporic, flat, green, autotrophic, cordate (Heart shaped), multicellular, short lived, small reduced, dorsiventral, free living independent, nonvascular gametophyte called prothallus.
- 10. (c) Require water for fertilization as their sperms are motile.
- (d) Botanical snake: The leaves of "Ophioglossum" pteridophyte is like hood of black snake cobra.
- (b) Heterosporous pteridophytes (e.g., Isoetes, Selaginella, Marsilea etc.) produce unisexual (dioecious) gametophytes. The development of gametophyte is endosporic (grow within spore wall).
- 17. (c) Pteriodphytes are first vascular land (tracheophytes) to have independent, sporophyte diploid plant body with true root, stem and leaves.
- **18.** (b) Sorus (sori = pleural) : It is a group of sporangia attached on placenta in ferns.
- 19. (c) In xylem, vessels are absent and in phloem, companion cells are absent. Selaginella and Equisetum are exception where vessels are present.
- 23. (a) Apospory was first observed by Druery (1884) in Athyrium filix-femina. Apospory is the formation of complete embryo sac from the sporophytic cell without meiosis so that the gametophyte remains diploid.
- 24. (a) Seed habit are fulfilled by few pteridophytes like Selaginella rupestris, S.monospora, Marsilea and Isoetes.
- 25. (a) Ginkgo is a Gymnosperm.
- 26. (c) They along with cycadofilicales are chief coal formers. The age of great coal forming forest belong to this period (carboniferous period). India coal belongs to permian period.
- (a) Apogamous cells are part of gametophyte, thus they are haploid.
- **28.** (b) The central pith is surrounded by xylem, phloem, pericycle and endodermis. The phloem occurs only out side the xylem *e.g.*, *Osmunda*.

Pteridium, Pteris, Dryopteris

- (d) In Pteridium, male and female sex organs are develop on one gametophyte.
- 2. (d) Ferns exhibits diplohaplontic life cycle and heteromorphic alternation of ganerations. The phase gametophytic are sporophytic and morphologically, functionally and cytologically distinct and occur in alternate manner due to meiosis and fortilization
- 3. (c) Antheridium producing about 32 antherozoids. Each antherozoid is large uninucleate coiled and multiflagellate.
- (a) Eusporangiate type of sporangium develops from a group of superficial initials. They divide periclinally in to outer and inner.
- (a) A dictyostele consisting of two or more concentric rings of meristeles. e.g., Pteridium aquilinum.
- (c) In Dryopteris, true indusium is present because this arises from placenta (placental tissue) from which sporangia arise.
- **8.** (b) Sori are linear and submarginal in *pteris* and *pteridium* and median abaxial (lower) in *Dryopteris*.
- (b) Inside the sporangium, there are 16 spore mother cells which on meiosis (reduction division) produce 64 spores.
- 10. (c) In ferns, sopres germinate to form a prothallus.
- (a) They develop a thickening along their radial and inner tangential walls. This layer is called annulus.
- 13. (a) Neck is made up of 4 vertical rows of cells. Slightly curved and encloses on neck canal cell which is binucleated.
- **14.** (c) Younger parts of leaves and rhizome are surrounded by brown hairy structures called scales (ramenta).
- **15.** (c) In *Dryopteris* true inducium (A specially developed structure) is present.
- **21.** (c) Dominant stage of fern is sporophyte which is always a diploid structure.
- **23.** (d) Gametophyte is free living, photoautotrophic thalloid, also called prothallus. Prothallus bears rhizoids, antheridia and archegonia on its under surface.
- 24. (a) Young leaves show circinate ptyxis (venation) (water spring like coiling with the apex in the centre of the coil) to protect tip of frond.
- 25. (a) Fern prothallus bears male and female sex organs both.
- 26. (d) On sporophylls either on dorsal or on ventral side bear sporangium e.g., Pteris, Dryopteris etc. Leaves are megaphylls showy feather like and called fronds.
- **28.** (c) Foot is formed first, which absorbs water, minerals from prothallus.
- 29. (d) Ferns are generally the first colonizers of burnt down forest area. This is due to persistence of their underground rhizomes while the above ground parts get burnt up.

- 30. (b) Antheridial Jacket is single layered and 3-celled.
- 31. (c) The number of spores per sporangium are fixed in every species and 64 is the maximum number of spores in sporangium.
- (d) Ramenta: It is hairy structure which cover juvenile leaves in ferns.
- 36. (a) No pollen tube to carry sperms.
- 37. (a) Dictyostele : A siphonostele perforated by several overlapping leaf gaps. Each separate strand is called meristele. e.g., Dryopteris, Pteridium, Pteris etc.
- **38.** (b) Spores of ferns are always haploid so they represent gametophytic stage.
- **40.** (d) Apogamy: Origin of haploid plant (rare) in pteridophytes *e.g.*, from prothallus cells.
- 42. (a) The plants of pteridophytes are sporophytes. They reproduce asexually by forming spores in sporangia.
- 43. (d) Prothallus is haploid.
- 44. (b) Annulus controls and assists in spore dispersal by losing water. Annulus also helps in the ejection of spores with force like a sling.
- 45. (a) Sporangia develop in groups called sori. Sori develop on the under surface of leaves and leaflets, laterally or marginally.
- 46. (a) Each sporangium has a multicellular stalk and a biconvex capsule.

Selaginella

- (b) Selaginella show many of the several adoptions required to produce a seed. They are collectively called seed habit of Selaginella.
 - (1) Presence of heterospory.
 - Retention of megaspores inside megasporangium in S. apus and S. rupestris.
 - (3) Formation of two types of gametophytes etc.
- (a) The four megaspores derived from a megaspore mother cell may not always be functional. e.g., In. S. rupestris single megaspore is functional.
- (c) The endodermis is interrupted by large intercellular spaces. This is called the trabeculated endodermis (modified endodermal cell). This layer, due to presence of casparian strips is regarded as endodermis.
- (c) Stele has polystelic structure with xylem in the center, phloem on the outside and pericycle covering the latter in Selaginella.
- (a) Ramenta or scales are found is Pteris, Dryopteris (fern).
- (c) Sperms (antherozoids) of Selaginella are 128–256 in number and biflagellated sickle shaped (curved).
- 7. (b) Nucellus is the megasporangium of Pinus.

- (d) Heterosporous condition (Produce of two kind of spores i.e., Megaspore and microspore) found in Selaginella and Homosporous conditions (Produce one kind of spore) found in pteris (fern).
- (d) Williams, Goebel and Bower regard it as an intermediate structure between root and shoot hence an "Organ sui-genesis".
- 11. (b) Trabeculae endodermis: Endodermis having air chambers. The endodermis except in xerophytic species (S. lepidophylla and S. rupestris) is interrupted by large intercellular spaces. This is called the trabeculated endodermis.
- 12. (a) Selaginella is mainly found in damp shaded places. A few species are xerophytic (e.g., S. lepidophylla, S.pilifera, S. bryopteris).
- (c) In Selaginella, sporophytic and gametophytic generation are morphologically as well as genetically differ.
- (a) Roots present in Selaginella and rhizoids present in Funaria.
- 16. (a) In male gametophyte the first division leads to formation of a small prothallial cell and a large antheridial cell.
- 18. (b) A flap like outgrowth is present at the base on adaxial side called ligule. It may be fan-shaped or tongue shaped or lobed. Such leaves are called ligulate.
- 19. (c) The microspores on germination forms the male gametophyte and the megaspore forms the female gametophyte.
- **22.** (b) The main plant body of *selaginella* sp. is sporophyte which is diploid in condition.
- 23. (a) In dry conditions, the plant rolls up in to a compact ball and during the rainy conditions the ball on absorbing moisture becomes green again. Such plants are called resurrection plants.
- **24.** (d) Reduction division or meiosis is called as sporic meiosis and is specific type met within pteridophytes.

Gymnosperms (General)

- (d) Therophytes are those plants that survive in winter as a seed and complete their life cycle between the spring and autumn.
- (c) Archegonia is found in bryophytes, pteridophytes and gymnosperms and antheridia occurs in bryophytes and pteridophytes.
- (d) Gymnosperms are perennial trees and shurbs and woody large trees.
- (b) Anemophily or wind pollination occurs in gymnosperms.
- **15.** (a) Canada Balsam is used as a mounting for microscopic studies. The source is *Abies balsamea*.

- (c) The foliage leaves do not have lateral veins. Instead, transfusion tissue (hydrostereom) occurs internally for lateral transport.
- (d) (a) Cycadophyta → Fossil Williamsonia.
 (b) Coniferophyta → Fossil cordites.
- **20.** (d) Main plant body sporophyte of gymnosperm and angiosperm are made up of root, stem and leaves.
- (b) Ginkgo biloba, a gymnosperm, is at present confined to the eastern part of China and Japan.
- (a) Gnetum, Ephedra (Jointed fir) and Welwitschia. This is the only order in gymnosperms, where vessels are present in xylem.

Pinus

- (c) In Pinus annual ring consists of a zone of spring wood and autumn wood.
- (d) Pollination in Pinus takes place when two prothallial cell, one generative cell and one tube cell are formed.
- (d) Because pollen tube is present and dispersal of pollen grains by wind. So male gametes are not ciliate.
- 7. (c) Chilgoza is seed of Pinus.
- (c) Male cones arise in place of dwarf shoots on long shoots and thus are equivalent to dwarf shoots.
- 11. (b) Because endosperm is haploid (n) and formed before fertilization and megaspore mother cell divides reductionally to form a linear tetrad of haploid megaspores and microspore (= pollengrain) is the first stage of the gametophyte (n).
- 12. (a) Tracheidal cell present in xylem, vessels are absent.
- 13. (b) In Pinus, as the seed matures a thin layer of ovuliferous scale fuses with testa of the seed in the form of a wing, this help in the dispersal of seeds.
- (d) In Pinus seed there are many cotyledons (3–18 cotyledons).
- (b) Male prothallus (gametophyte) in Pinus is having two prothallial cells and one tube cell.
- 16. (c) Vascular strand is unbranched and covered by pericycle. It has generally two conjoint and collateral vascular bundles separated by T-shaped sclerenchyma.
- 17. (a) In the embryo of Pinus rosette tier (4 cells) above the suspensor tier and mediates between the suspensor tier and nutritive tier.
- (b) Resin is collected from the stem/wood of Pinus. It is distelled to produce turpentine and rosin.
- (d) Winged pollen grains produced in microsporangium which represents the male gametophyte of Pinus.
- 20. (b) In Pinus embryo with 3 to 18 cotyledons.
- 21. (b) Brown membranous scale leaves (cataphylls) present on both long and dwarf shoots and serve to conserve water around the branches.
- **22.** (c) Male gametophyte of *Pinus* is 4 celled (two prothallial cells, one generative cell and one tube cell).
- 23. (a) The wood of Pinus is pycnoxylic (more than one ring due to epimeral nature of cambium) and monoxylic (formed by the activity of single cambium).

- 25. (d) Because Pinus is gymnosperm plant.
- **26.** (d) Dwarf shoot: In case of Pinus, actually in dwarf shoot the number of *Pinus* needles varies from one to six.
- 27. (b) Resin (Terpentine oil): In Pinus roots, stem and needle, resin ducts are found having odorous oil known as resin. This resin is anticoagulant and do not allow to freeze water even upto 30°C temperature in Pinus plants.
- 28. (c) The sporogenesis results in the formation of micro and megaspores representing the first gametophyte cells. They undergo gametogenesis so as to form the male and female gametophytes respectively.
- (b) The 'endosperm' of Pinus is a haploid gametophytic tissue formed before fertilization.
- **30.** (a) In gymnosperms and angiosperms gametophytes are dependent on sporophyte.
- 31. (b) As the seed matures, a thin layer of ovuliferous scale is fused with testa of seed in the form of wings.
- 32. (a) The seed of Pinus:
 - (1) Parent 2n, sporophyte represented by wing, testa, tegmen and perisperm (nucellus).
 - (2) Female gametophyte (n) represented by enclosperm.
 - (3) Future sporophyte (2n) represented by embryo (Plumule, radicle, suspensor and cotyledons).
- **33.** (a) Body cell divides into two daughter cells just before fertilization. These two cells are known as sperms.
- 34. (c) Seed of Pinus is endospermic, perispermic diploid (2n). The wing of seed is thin, membranous diploid (2x) and develops jointly from the basal upper surface (adaxial) of ovuliferous scale and outer layer of integument of the ovule.
- 35. (a) Monoecious
- **36.** (b) In *Pinus* the pollination is anemophilous, (wind) i.e., pollen grains are carried to the ovule through wind.
- **38.** (b) Female cone are morphologically equivalent to long shoot because female cone is 1.8 to 3 cm in 1st and 2nd year and 45 cm in length and 10 cm wide in third year.
- **39.** (d) Siphonogamous fertilization: The fertilization in which a long pollen tube carry two male sperms near to egg cell is called as siphonogamous fertilization. This is only found in gymnosperms and angiosperms.
- **40.** (c) Four embryos are formed from a single fertilized egg in cleavage polyembryony simple polyembryony *i.e.*, When more than one embryos are developed as a result of fertilization of different archegonia.
- **41.** (c) The microsporophylls of *Pinus* has 2 microsporangia on its abaxial surface.

Cycas

- (c) Diploxylic vascular bundles : In cycas leaflet, in central V.B. two xylem and one phloem is found.
- 2. (a) The sperms of cycas are largest (300μ) in nature and visible to naked eye.
- (c) Fern character in cycas is circinate venation in which younger leaf is coiled like a spring from apex downwards.

- (a) Anabaena, Nostoc and bacteria are found in coralloid roots hence it helps in fixation absorption of nitrogen.
- (d) A starch called sago is obtained from the pith of cycas, that so cycas is called sago palm.
- (a) In the female plant, the apical meristem remains unaffected. Hence, the growth pattern is monopodial.
- (a) The terminal sterile portion of the sporophyll is called apophysis.
- (a) In one young seed only one embryo remains at maturity and others perish are called potential true polyembryony.
- (c) Secondary growth is carried by successive rings of cambia (as many as 22 rings of vascular tissues are observed).
- (c) Living fossil is that organism whose relatives have become extinct (Fossilised) and has a restricted distribution, therefore, threatened to become extinct.
- 14. (d) The sperm of Cycas is remarkably large in the entire plant kingdom. It is top shaped with 4-5 spiral coils of cilia at anterior half.
- 15. (c) Vessels is a characteristic feature of angiosperms.
- 16. (d) Size of largest ovule 6 cm (length) 4 cm (dia), size of largest sperm 300μ, size of largest egg 0.5 mm in diameter.
- (b) Cycas is dioecious in which male and female sex organs are present in a single plant.
- 18. (d) Sago palm rich in starch.
- 19. (b) Monoxylic and Polyxylic: The wood is loose, soft, nonporous commercially useless, parenchymatous tissue more, vascular tissue less pith and cortex broad, medullary rays wide e.g., cycas wood.
- 20. (a) Stem pith of cycas having a number of mucilage canals.
- 21. (a) The pollination is an emophilous. The pollen grains of cycas are light in weight and easily blown away be wind.
- 22. (a) The megasporophylls is distinguishable in to a rachis part and a distal lamina in the upper part of the rachis are present to pairs of ovules, laterally.
- **25.** (b) The 'endospoerm' in *cycas* is a haploid gametophytic tissue formed before fertilization.
- 26. (d) The male gametes of cycas are largest (300μ) in nature, broad and naked at posterian end and spirally coiled in the anterior half with thousands of small cilia.
- **27.** (d) Anabaena with coralloid roots is an example of symbiosis. It helps in N_2 fixation.
- **29.** (a) The pollen grains at this 3 celled stage fall directly on the pollination drop secreted by ovule as there is no stigma to receive pollen grains.
- **30.** (b) Because sago is easily digestible with less starch (31%).

- 31. (a) Vessels are absent in gymnosperms.
- (c) Bulbils (cresting adventitious buds), which are produced on the stem in the axil of scale leaves.
- (a) Gynoecium is megasporophyll. Megasporophyll has stigma, style and ovary.
- **34.** (d) In Cycas seeds are naked because it is not covered by ovary.
- (d) Leaflet of cycas is diploxylic means 2 types of xylem centripetal (exarch) and centrifugal (endarch).
- 36. (b) Microsporophyll bear sori of sporangia on the abaxial surface because the terminal portion is sterile.
- 38. (b) Motile sperms are found in both Cycas and Adiantum, Seeds, cambium are quite common in gymnosperms absent in pteridophytes.
- (c) In young condition, young leaves show circinate ptyxis like fern leaves and are covered by ramenta.
- **40.** (b) The zygote, which is the first sporophytic cell, undergoes free nuclear divisions.

Angiosperms

- (b) In monocots vascular bundles are conjoint collateral, closed scattered are called Atactostele.
- (c) In dicots tap roots and in monocots adventitious roots is present.
- **6.** (d) Phanerogams means seed bearing plants. Gymnosperms and angiosperms both possess seeds.
- (d) In Angiosperm seeds are enclosed within a hollow ovary.
- 10. (b) Dicots are considered primitive over monocots.
- (d) Secondary growth takes place in angiosperms because cambium are present (except monocots).
- (b) The tip of the root of Rafflesia makes haustorial contact with the root of host and absorbs food from the host.
- **15.** (a) Male gametophyte is highly reduced in angiosperm and is known as pollen grain. It is 2 or 3-celled.
- **16.** (d) Megaspore Mother Cell (MMC) undergoes meiosis to form megaspore.

Critical Thinking Questions

- (b) Adiantum Maiden Hair fern (because of shining, smooth and blackish hair like petioles).
- 2. (d) Seeds are formed after fertilization and consequent enlargement of the ovule. Two ovule or megasporangium are present on the adaxial side of ouvliferous scale. The ovuliferous scale and bracts constitute the megasporophyll.
- **6.** (c) Because archegonia of *Pteris* secrete a chemical malic acid which attracts only sperms of *Pteris* chemotactically.
- (d) Equisetum Pteridophytes-Free living gametophyte Prothallus.

Riccia – It is liverwort in which simplest sporophyte consists of capsule only while polytrichum is moss in which sporophyte consists of foot seta and capsule.

Volvox - oogamy is present.

Slime moulds - Spores bear cell wall.

- 9. (a) Such a sporangium arises from a single superficial initial. It divides periclinally into outer and inner components. While the inner cell forms the stalk, the outer gives rise to sporangium proper. In Marattia alata, the sporangia in a sorus may fuse to form a synanjoi.
- (a) Because endosperms of Pinus are always haploid and is formed before fertilization in ovules.
- **12.** (d) The Microspores divides to form a 13 celled non-green, male gametophyte (one vegetative/prothallial cell + 8 jacket cell + 4 primary androgonial cells).
- (d) Stigeoclonium shows heterotrichous habit which differentiated into prostrate and erect system.
- 15. (b) A Mosses and lichen are pioneers on rocks
 B Selaginells is heterosporous
 C Coralloid roots of cycas has cyanobacteria –
 Anabena cycadae
 D and E are correct.
- 16. (d) The male cones are borne in a cluster on a branch of unlimited growth behind the apical bud, in the axil of a scale leaf. A cone consists of a central axis bearing 60-135 microsporophylls in spiral manner. It is therefore, comparable female flower of angiosperm.
- 17. (a) Some red algae deposit calcium carbonate on their surface. They are called coralline algae e.g., Corallina. They help to develop coral reefs alongwith corals.
- (c) In ferns gametophytic generation is represented by heart shaped prothallus.
- (b) Calyptra is a outermost protective covering of moss and liverwort.
- **21.** (d) Zea is monocot, Cycas have two and Pinus have many cotyledons in their embryo
- (c) Heterospory, seed formation and fertilization are found in gymnosperm.
- **24.** (d) The male gametes of *Riccia* and *Dryopteris* have flagella while male gametes of *Cycas* have cilia.
- (d) The fertilization takes place after about a year of pollination.
- **26.** (b) Sporophytes and gametophytes are morphologically differ in *Funaria*, *Selaginella* and *Cycas*.
- 27. (c) (A) Cyanophyceae The blue-green colour is due to presence of a phycobilin pigment c–phycocyanin (also c–phycoerythrin).
 - (B) Chlorophyceae The green colour is due to presence of a chl. – a, chl. – b, xanthophylls and carotens.
 - (C) Phaeophyceae Brown colour is due to presence of pigment 'fucoxanthin'.
 - (D) Rhodophyceae Colour is red due to presence of a red pigment (r–phycocyanin) in the chromatophores.
- **28.** (b) Endosperm in gymnosperms is formed before fertilization and is always haploid.
- **29.** (b) In *Pteris* antheridum is having (about 32) multiflagellated, coiled (2 3 coils) antherozoids or spermatozoids.
- **30.** (c) Apospory is the formation of gametophyte directly from sporophyte without the meiotic formation of spores.

- **31.** (d) At the base of ligule there is present a sheath of elongated cells called glossopodium (secretory). This ligule is secretory as well as protective. It secrets water/mucilage to keep growing point of stem and young leaves moist. It also protests young leaves.
- 34. (d)
 - (1) Moss of Bryophytes bears protonemal and leafy stage.
 - (2) Gymnosperm female gametophyte is not free living.
 - (3) They are present in Marchantia of Bryophyte.
 - (4) Origin of seed habit started in Selaginella.

Assertion and Reason

- (b) Biennial plants live for two favourable seasons.
 During the first season, the plants grow in size and store food. In the second season, they bear flowers that form fruits.
- 2. (b) Bryophytes and tracheophytes possess an embryo stage. They are collectively called embryophyta. Bryophytes and tracheophytes are terrestrial plants. Bryophytes are nonvascular while tracheophytes possess vascular tissue.
- 3. (b) Stamens are specialized microsporophylls. Each stamen has a narrow stalk or filament and a knob-like broader tip called anther. Anther develops four microsporangia or pollen grains. Carpels are specialized megasporophylls. Each carpel has a swollen base named ovary. The interior of ovary contains one or more placentae for bearing ovules.
- 4. (a) On the basis of
 - (i) Thallus like non-vascular plant body,
 - (ii) Simple, unicellular non-jacketed sex organs and
 - (iii) No embryo development after gametic union, the algae and fungi have long been grouped together in thallophyta. The algae and fungi are the result of parallel development and do not indicate any phylogenetic relationship.
- (a) The colour of the algal thallus which varies in different classes of algae is due to the presence of definite chemical compounds in their cells. These are called the pigments. Each pigment has its own characteristic colour. The particular colour that an alga has is due to the predominance of one pigment in a combination of several others. Each group of algae has its own particular combination of pigments and a characteristic colour which is not found in other algal groups.
- 6. (a) The red algae flourish and occur in abundance at great depths of sea where other plants do not occur in abundance. The sunlight as it penetrates water, portions of spectrum such as red, orange, yellow and green light rays which are of short wavelengths are filtered out. Only the blue and violet rays of great wavelength remain and penetrate to great depths. The green pigment chlorophyll cannot trap these light rays of great wavelength and the green plants are thus unable to carry on photosynthesis at these depth. On the other hand the red pigment r phycoerythrin and a blue pigment γ phycocyanin which are characteristic pigments of all the red algae, can utilize wavelengths of light (blue and violet rays) not absorbed by chlorophyll.

- 7. (e) The carpogonium (female sex organ) in Nemalion, one of the simplest red alga, consists of a swollen basal part containing the female nucleus and an elongated terminal hair-like structure called the trichogyne. During fertilization the spermatium (male gamete) discharges its contents into the latter. The spermatium nucleus migrates downwards to fuse with the egg nucleus in the basal swollen part of the carpogonium. Soon after fertilization the trichogyne shrivels.
- 8. (a) In Spirogyra, the outermost portion of pectose changes into pectin. The latter dissolves in water to form the so called gelatinous sheath which is slimy. It envelopes the entire filament. This makes filament slippery in touch.
- 9. (c) The fusing gametes in the lower forms of algae are alike in size, structure and behaviour. They are indistinguishable as to sex. Such gametes are called the isogametes. Sexual reproduction which involves the fusion of isogametes is termed isogamous. It is a primitive type of sexual reproduction.
- 10. (a) Angiosperms is the highly evolved group of plant kingdom. It is adapted for terrestrial habitats. Swimming habit of sperms is completely lacking in angiosperm. The pollen grains reached to the stigma by an external agency and delivered the male nucleus in the ovule through pollen tube.
- 11. (b) Fertilized ovules ripen into seeds. The seeds are covered by fruits. A fruit is technically a ripened ovary. Gymnosperms contain ovules but they lack ovary, therefore, seeds are formed but fruits are not formed. Angiosperms contain both ovule and ovary and therefore, are seed bearing fruit forming plants.
- 12. (b) The chloroplasts of green algae contain one or more distinct, rounded, proteinaceous bodies called the pyrenoids. Pyrenoids diminish in size and ultimately disappear if the plant is under conditions of starvation. They reappear when the conditions become favourable.
- 13. (c) In green algae the eye spot is usually associated with the chloroplast. Eye-spot is considered as a photoreceptive organ.
- 14. (b) Chlorella could be utilised to keep the air in space vehicles pure and supply food in space stations and prolonged space flight trips. The space travellers could feed on Chlorella soup. It is nourishing but not appetizing food.
- 15. (b) In angiosperm, sporophylls are organised into flowers. Both microsporophylls and megasporophylls are specialised. A microsporophyll or stamen consists of a filament and an anther. A megasporophyll or carpel is rolled and partly sterilised to produce a stigma, style and ovary containing ovules.
- 16. (c) Many believed that *Chlorella* could serve as a potential source of food and energy because its photosynthetic efficiency can theoritically reach 8% comparable with other highly efficient crops nutrients. When dried, it has about 45% protein, 20% fat, 20% carbohydrate, 5% fibre and 10% minerals and vitamins.

- 17. (a) A life cycle characterized by a haploid thallus, and zygotic meiosis is called haplontic life cycle. It is also called as haplobiontic because only a single type of free living individual is involved in the life cycle. Spirogyra shows haplontic life cycle and therefore, it also shows zygotic nucleus.
- 18. (a) In some species of red algae called coralline algae, the cell walls become hardened with calcium carbonate. These algae hence important for the formation of coral reefs. Coral reefs are formed through the accumulation of calcareous exoskeletons of coral animals, calcareous red algae and molluscs. They form the foundation of reefs by secreting a calcium carbonate skeleton and provides protection for the coral polyps. Calcium carbonate is secreted continuously by the coral colony.
- 19. (a) Bryophytes are a group of non-vascular land plants. The sex organs in the bryophytes are multicellular and jacketed. The jacket of sterile cells around the sperms and eggs is an adaptation to a life on land. It protects the sex cells against the drying effects of air.
- 20. (e) Most of the bryophytes are land dwellers which inhabit damp, shaded and humid localities. A few of them live in or float on water. The bryophytes cannot carry on their reproductive activities without sufficient moisture. Presence of water is necessary.
- 21. (c) The bryophytes have evolved a life which comprises two phases-gametophyte and sporophytes. The gametophyte (haploid) is concerned with sexual reproduction and constitutes the most conspicuous, nutritionally independent phase in the life cycle. The sporophyte is dependent partly or wholly on the gametophyte for nutritional purpose.
- 22. (c) Thallophytes, i.e., algae and fungi completely lack the formation of embryo. In bryophytes, the zygote, on germination, does not produce the gametophyte plant. It undergoes segmentation to form an embryo. The embryo (diploid) by further segmentation and differentiation gives rise to sporophyte. The sporophyll obtains its nourishment directly from the parent gaemtophyte to which it is organically attached.
- 23. (c) The female sex organ of the bryophytes is a remarkable structure. It appears for the first time in the liverworts and mosses and continues in the pteridophytes. Archegonium is absent in thallophytes (algae and fungi). Sex organs in them are male gametes and female gametes.
- 24. (d) In bryophytes, the zygote, on germination, does not produce the gametophyte plant. It undergoes segmentation to form an embryo. But the embryo formation and its development to sporogonium and sporophyte are dependent on gametophyte plant as the sporophyte is dependent on the gametophyte for nutrition. They remain attached organically to the gametophytic plant. In algae, the zygote is independent and it does not form the sporophyte.
- 25. (b) Fragmentation leads to increase in the number of plants in a locality but it does not permit spread of the plant to an entirely new locality. Being small and sufficiently buoyant, gemmae are easily carried. When detached, they spread by water and wind currents to new habitats, where each grows into a new individual immediately.

180 Plant Kingdom

- 26. (b) Pinus show alternation of generations. The sporophyte phase is of long duration and is represented by the huge pine tree, which bears the staminate and ovulate cones. Since meiotic divisions occur at the same time of the differentiation of the pollen grains and megaspores.
- 27. (e) In Pinus, the embryo is straight and consists of a short axis bearing a ring of about ten slender, yellow cotyledons at the end, away from the micropylar end. In Pinus, more than one embryo come from a single egg by the splitting of the product of a single fertilization, termed as cleavage polyembrony.
- 28. (b) The ovulate or female cones take three years to mature. The mature cones are hard, woody and very large in size. Many important changes take place in the female cone during the interval of about thirteen months between pollination and the actual act of fertilization.
- 29. (d) Female cones or ovulate cones are fewer in number and arise single or in a small cluster or two to four, each as a bud in the axial of a scale leaf towards the end of the new shoots of unlimited growth (long shoots) which do not bear the male cones.
- 30. (a) Each sperm of Riccia is a minute, slender curved structure. It is furnished with a pair of whiplash flagella at its anterior end. The sperms do not leave the antheridium until enough moisture is present to permit them to swim about. Several of the sperms may swim downward in the liquid in the neck.
- 31. (a) The sporogonium (capsule) of Riccia is the simplest among the liverworts. It lacks both the foot and the seta. There are no elater. Unlike other liverworts the embryo, sporogonium and spore mother cells in Riccia develop no chloroplasts. Thus no photosynthesis occurs there. The sporophyte remains totally dependent upon the gametophytic thallus.
- 32. (b) In young stems of Funaria, the cortical cells contain chloroplasts, hence, they are photosynthetic. The central cylinder forms the core of the stem. It consists of vertically elongated, thin-walled, narrow, compactly arranged cells without protoplasm. These thin walled, elongate, dead cells with nonlignified walls are commonly called the hydroids.
- 33. (c) Pinus is monoecious as it bears both types of cones on the same tree on separate branches. The male cone consists of a number of small spirally arranged microsporophylls. Each microsporophyll bears two microsporangia or pollen sacs as swelling on the lower surface of its horizontal position.
- 34. (c) The formation of small, underground resting, budlike structures called the tubers has also been reported in some mosses. Formerly these underground bud-like structures were called the bulbils. The tubers develop singly on stem, leaves and rhizoids as small, spherical storage organs containing starch. These serve as means of perennation and enable the plant to tide over periods unfavourable for vegetative growth.

- 35. (e) In Funaria, the gemmae develop on the stem and leaves of the gametophore at the onset of condition unfavourable of growth or during injury. These detached gemmae under conditions favourable for vegetative growth directly develop into new leafy gametophores.
- (b) Morphologically Funaria looks dioecious, but it is monoecious.

The antheridia (male sex organ) are formed at the summit of a relatively small, main leafy shoot which develops first. It is in fact the parent plant.

The female branch arises later as a lateral outgrowth from the base of the parent male shoot. When the two kinds of the sex organs are borne in separate clusters on two distinct branches of the same plant the arrangement is called monoecious. *Funaria* is protandrous (male matures first). This ensures cross fertilization.

- 37. (e) In Funaria, the antheridia are not sunk in pits, but project from the surface of the receptacle and are aggregated to form a cluster. The leaves surrounding the antheridial cluster are known as the perigonial leaves. The antheridial cluster with the surrounding perigonial leaves is called the perigonium.
- 38. (b) The peristome teeth are present at the mouth of capsule. The teeth may be solid cellular tissue or composed only of the thickened portions of the cell walls of adjacent cells.

When the teeth of peristome are solid structures composed of bundles of dead cells, it is termed nematodontous peristome are solid structures composed of bundles of dead cells, it is termed nematodontous peristome. It is found in polytrichum, Pogonatum and Tetraphis. If peristome composed of thin, membranous, transversely barred teeth, each tooth is made up of the thickened portions of the cell walls of adjacent cells. Such a peristome is called orthodontous.

- 39. (b) Within the hypodermis of Pinus leaf is the parenchymatous mesophyll. It is compart and shows no differentiation into palisade and spongy tissues. It consists of thin walled cells which contain numerous chloroplasts and abundant starch. The mesophyll thus functions as the chlorophyll bearing tissue which manufactures food for plants.
- 40. (a) Secondary growth takes place in the manner similar to dicotyledonous stem. The secondary word shows well marked growth rings which are formed annually due to environmental fluctuations. Each annual ring possesses a zone of spring and an autumn wood. Spring wood is formed during season under availability of enough water and minerals. It possess large polygonal, thin walled and wide tracheids with large bordered pits. Autumn wood is formed during Autumn season. It possesses smaller, squrish, thick walled and narrow tracheids with small bordered pits. It is evident that the size of tracheids shows a marked variation with regard to amount of nature available in the respective season.

- 41. (a) Rubling and Tyler (1979) showed that air dried mosses can absorb metals. The accumulation of heavy metal cations in mosses enables them to be used as pollution indicators.
- 42. (a) According to some Botanists, Mosses originated from algae. Protonema of mosses is similar to certain algae.
- 43. (c) In the sproangia of Pteridium are not grouped together in small separate sori, but the sorus is continuous along the under margin of the pinnules, often for considerable distances. This type of sorus is known as continuous linear sours (coenosorus).
- 44. (b) Indusium is an epidermal membranous outgrowth covering the sori in some ferns. The coenosorus is surrounded by two well formed indusial lips, between which lies the receptacle. The outer indusial lip is well-developed and is formed by the reflexed margin of the pinnule, which overlaps the coenosorus and its sporangia. This is commonly called the false indusium.
- 45. (b) In Dryopteris, young rhizome and leaves are covered with dry, brown, chaffy scales known as ramenta. In Pteridium, the rhizome and the leaves especially while young, are covered by a felt of simple hairs, and the scales are conspicuously absent.
- 46. (d) The scale leaves are present both on the long and dwarf branches. They fall off as the branches mature. The scale leaves on the dwarf shoots are called the cataphylls and possess a distinct midrib.
- 47. (d) In bryophytes, antheridia are well developed and often possess a stalk. In pteridophytes, antheridia are less developed and generally devoid of a stalk whereas pteridophytes has multiflagellate sperm formed from androcyte cell of antheridium. Bryophytes has biflagellate sperm.
- 48. (e) In fern, fertilization usually takes place if the prothalli are watered from above as they would be by rain in the ordinary course of nature. They possess flagella for swimming movement towards archegonia through water.
 - The discharged matter at the mouth of the opened archegonial neck probably contains some chemical substance, e.g. malic acid, which by positive chemotaxis attracts the free swimming antherozoids, which penetrate the neck and reach the deeply seated ovum.
- 49. (c) In the pteridophytes, the sporophyte gains physiological independence and develops into the dominant, typically photosynthetic phase of the life cycle. It is organized into stem, leaves and roots. For the first time in the sporophyte of the pteridophytes true roots develops. Psilophyta (a pteridophyte division) lack true roots.

- 50. (e) In gymnosperms, xylem lacks true vessels and wood fibres. It consists of tracheids that are arranged in uniform radial rows and xylem parenchyma only. The phloem contains sieve tubes and parenchyma cells. There are no companion cells.
- 51. (d) In eusporangiate type of development, large sporangia develop from a group of initials. In leptosporangiate type of development, small sporangia develop from a single initial, the former builds the entire sporangium, its contents and stalk and the latter takes no part in the process.
- 52. (a) Leaf tips of Adiantum caudatum, develop adventitious buds for vegetative propagation. When leaf tip reaches the ground, it develops into new plant, therefore, it appears that the plant is walking.
- 53. (a) The gymnosperms have their ovules freely exposed before and after fertilization. They are not enclosed by any ovary wall. The seeds formed by them lack seed coat. Hence due to absence of every wall and seed coat their seeds are nacked.
- 54. (b) Long branches of Pinus become gradually shorter towards the apex. Hence the pine tree has a conical or pyramidal appearance. Long branches bear short branches and older portion of long branches show the scars of fallen short branches.
- 55. (c) In Cycas there is no true and compact or properly organised female cone. Megasporophylls are loosely arranged and thus form a loose female strobilus. The growing point of the stem is unaffected by their development and continues its growth through the loose strobilus.
- 56. (c) All living species of Cycas are dioecious as the male and female structures occurs on separate plants. The microsporophylls are aggregated into large compact male strobili or cones. The megasporophylls are loosely arranged. They do not form a true cone.
- 57. (b) When the microspores reach maturity, the male cone elongates considerably and rapidly. The scales separate from one another so that sporangia are exposed. The sporangia lose water and with the loss of water from its cells the exothecium shrinks. The sporangia thus open by a slit on its outer face. The spores fall out. The liberated spores are dispersed by wind.

Plant Kingdom

FT Self Evaluation Test

- In ferns, xylem is 1.
 - (a) Exarch
- (b) Mesarch
- (c) Endarch
- (d) Polyarch
- Tracheophyte includes 2.

[Odisha JEE 2009]

- (a) Pteridophyte, gymnosperm and angiosperm
- (b) Bryophytes and spermatophytes
- (c) Only spermatophytes
- (d) Thalophytes and bryophytes
- Heterospory and seed habit are often exhibited by a plant [CBSE PMT 1997; BVP 2009] possessing
 - (a) Bract
- (b) Spathe
- (c) Petiole
- (d) Ligule
- Match items in Column I with those in Column II

Column I

Column II

- (A) Peritrichous flagellation (J) Ginkgo
- (B) Living fossil
- (K) Macrocystes
- (C) Rhizophore
- (L) Escherichia coli
- (D) Smallest flowering plant (M) Selaginella
- (E) Largest perennial alga (N) Wolffia

Select the correct answer from the following

[CBSE PMT 2005]

- (a) A L; B J; C M; D N; E K
- (b) A K; B J; C L; D M; E N

- A female gametangium of bryophyte differs from that of 5. fungus in possessing
 - (a) Large neck
 - (b) A venter
 - (c) Jacket layer with sterile cells
 - (d) A single egg cell
- Annulus of moss capsule separates [CMC Vellore 1993] 6.

- (a) Operculum and columella(b) Theca and columella
- (c) Theca from operculum (d) Columella from apophysis
- The microspore of Selaginella may be as small as[MP PMT 2011]
 - (a) 5μ
- (b) 15µ
- (d) Sµ
- The major role in the dehiscence of a fern sporangium is [AIIMS 1999] played by its
 - (a) Annulus
- (b) Indusium
- (c) Tapetum
- (d) Sorus

- Leaf gap in the vascular cylinder in ferns is
 - (a) Air space
- (b) Parenchymatous zone
- (c) Collenchymatous zone
- (d) Area exclusively of phloem
- The female sex organ in Riccia and Funaria is

[AIIMS 1992; BHU 1994]

- (a) Archegonium
- (b) Antheridium
- (c) Oospore
- (d) Paraphyses
- The sclerenchyma of the hypodermis in the Pinus needle [AIIMS 1992] helps in
 - (a) Checking transpiration
 - (b) Mechanical support
 - (c) Photosynthesis
 - (d) Increasing the absorptive surface of the cell
- Which one of the following characters in not shown by Selaginella
 - (a) Circinate venation
- (b) Precocious germination
- (c) Microphyllous leaves
- (d) Protostele
- Match the following

A.	Red Algae	1.	Marchantia
B.	Liver wort	2.	Pinus
C.	Walking fern	3.	Polysiphonia
D.	Gymnosperm	4.	Adiantum

- Select the correct statement 14.

[Kerala PMT 2011]

- (a) Absorption of water by seeds and dry wood are examples of facilitated diffusion
- (b) The apoplast is the system of interconnected protoplasts
- (c) Pinus seeds cannot germinate and establish without the presence of mycorrhizae
- (d) The translocation phloem is unidirectional whereas in the xylem it is bidirectional
- In bryophytes an operculum a cap like structure develops 15. [CPMT 1993]
 - (a) Antheridium
- (b) Archegonium
- (c) Both (a) and (b)
- (d) None of these
- Number of flagella in male gametes of fern is [RPMT 1995]
 - (a) Zero
- (b) One
- (c) Two
- (d) Infinite

Plant Kingdom 183

- Well developed archegonium with neck consisting of 4–6 rows of neck cells characterises [CBSE PMT 1995]
 - (a) Gymnosperms and flowering plants
 - (b) Bryophytes and pteridophytes
 - (c) Gymnosperms only
 - (d) Pteridophytes and gymnosperms
- 18. Meiosis (reduction division) in pteridophytes takes place at the time of [MP PMT 2003; AFMC 2004]
 - (a) Spore formation
- (b) Sexual organ formation
- (c) Germination of spores
- (d) Gamete formation
- 19. Which organism lacks archegonium

[MP PMT 2011]

- (a) Funaria
- (b) Pteris
- (c) Cycas
- (d) Spirogyra
- 20. Laminaria (kelp) and Fucus (rock weed) are the examples of [AFMC 2000; CBSE PMT 2001; BVP 2002; AMU (Med.) 2009; Kerala PMT 2012]
 - (a) Green algae
 - (b) Brown algae (Phaeophyceae)
 - (c) Red algae (Rhodophyceae)
 - (d) Golden brown algae
- 21. Rhizoids in Funaria arise from [CPMT 1998; MHCET 2003]
 - (a) Basal region
- (b) Ventral region
- (c) Dorsal region
- (d) None of these
- 22. The walking fern is so named because [CBSE PMT 1998]
 - (a) Its spores are able to walk
 - (b) It is dispersed through the agency of walking animals
 - (c) It propagates vegetatively by its leaf tips
 - (d) It known how to walk by itself

Answers and Solutions

1	b	2	a	3	d	4	a	5	C

21	a	22	С						0.000

- (b) Mesarch: When in xylem, protoxylem and metaxylem are mixed then in ferns xylem becomes mesarch.
- 3. (d) Heterospory meant for the production of two different sizes of spores i.e., microspore and megaspore. It is found in Selaginella. In Selaginella, there is a small membranous ligule found at the basal portion of the leaf.
- (c) A female gametangium of bryophyte differ from fungus multicellular sex organs surround by a single layered jacket of sterile cells.
- 6. (c) Capsule has three parts lower assimilatory apophysis, middle spore containing theca (with central sterile columella) and upper part having an operculum, peristome and annulus.
- (b) The parenchymatous region left behind in the main stele after the departure of the leaf trace is called 'leaf gap'.
- 11. (b) Because sclerenchyma are thick wall cells.
- 12. (a) Circinate vernation is characteristic feature of division filicophyta (e.g., Dryopteris) while Selaginella include in division lycophyta.
- (b) The upper region of capsule is slightly oblique having upper cap-like portion called operculum.
- 16. (d) Male gametes of fern is multiflagellated.
- (a) In pteridophytes, spore mother cell undergo meiosis to form tetrahedral tetrads of spores.
- 20. (b) The large (giant) parenchymatous forms of brown algae are called kelps or sea weed or trees of seas or forest of sea. (e.g., Maccrocystic 30–60m; Nereocystis 20–30m, Laminaria 2–12m). Both contain fucoxanthin, which is brown in colour. Due to which both are grouped under brown algae.
- (a) On the lower portion of the leafy gametophore, there are present branched, multicellular rhizoids with oblique septa.
- 22. (c) Adiantum caudatum walking fern because its leaf tips when come in contact with soil, form new plants as adventitious buds develop at leaf tips. This helps in the spread of fern over a large soil surface and thus derives the name walking fern.

Important terms and Classification of animals

The kingdom animalia or animal kingdom is the kingdom of consumer organisms having ingestive type of nutrition. It is the largest kingdom, with 1.2 million members. It has numerous organisms having different type of form, structure, organisation, complexity and development.

General features of animals

The animals possess several general features which taken together, distinguish them from the members of other kingdom.

- (1) Animals are multicellular eukaryotes and in most cases their body cells form tissues that become arranged as organs and organ systems.
- (2) Animals have heterotrophic mode of nutrition. They get carbon and energy by ingesting other organism or by absorbing nutrients from them. Animals may be herbivores, carnivores, omnivores, parasites, suspension feeders or deposit feeders.
 - (3) Animals require oxygen for aerobic respiration.
- (4) Animals are motile, possess active movement during some stage of their life cycle. Even the sessile sponges have free swimming larval stages.
- (5) The animal body cells of nearly all species have diploid chromosome number.
- (6) Animal cells lack a cell wall; this provides flexibility to their cells, the most striking characteristic of animals.
- (7) Animals are able to make rapid responses to external stimuli as a result of the activity of nerve cells, muscle or contractile tissue or both.
- (8) Animals can reproduce sexually. Although some exhibit remarkable diversity of reproductive behaviour, all are capable of sexual reproduction.
- (9) Animal life cycle includes stages of embryonic development. Mitotic cell divisions (cleavage) transform the animal zygote into a multicellular embryo.

Terms related to classification

- (1) **Anaima**: Animals without red blood e.g., sponges, cnidaria, mollusca, arthropoda, echinodermata, etc.
 - (2) Enaima: Animals with red blood e.g., vertebrates.
- (3) **Vivipara**: Animals which give birth to young ones are included in this subgroup *e.g.*, man, dogs, cows, etc.
- (4) **Ovipara**: Animals which lay eggs are included in this subgroup *e.g.*, frogs, toads, lizards, snakes, birds, etc.
- (5) **Anamniotes**: Vertebrates without embryonic membranes *e.g.*, fishes, amphibians.
- (6) Amniotes: Vertebrates with embryonic membranes (chorion, amnion, allantois, yolk sac) e.g., reptiles, birds, mammals.
- (7) Acraniata or Protochordata: Chordates without cranium (brain box). It includes urochordata and cephalochordata.
- (8) **Chordates**: Animals with notochord dorsal tubular nerve cord, paired pharyngeal gill slits. All urochordates, cephalochordates and vertebrates are called chordates.
- (9) Craniata or Vertebrate: Chordates with cranium. It includes cyclostomes, pisces, amphibians, reptiles, birds and mammals.
- (10) Nonchordates: Animals without notochord (a rod like elastic structure which supports the body). Phylum Porifera to phylum Hemichordata are called nonchordates.
- (11) **Invertebrates :** Animals without vertebral coloumn (backbone). All the nonchordates, urochordates and cephalochordates are collectively called invertebrates.
- (12) Levels / Grades of organization : Four levels of organization are found in multicellular animals.
- (i) Acellular or Molecular or Protoplasmic level: It is present in protozoans.

- (ii) Cellular level: The body consists of many cells which may be similar or show minor division of labour. Distinct tissues are not formed, e.g., sponges.
- (iii) **Tissue level :** The body is multicellular. The cells form poorly defined tissues. The cells occur in two distinct layers or tissues of specialized cells *e.g.*, coelenterates.
- (iv) **Organ-system level**: The body is multicellular. The cells are organised into tissues, tissues into organs and organs into organ systems. Except sponges and coelenterates, all the animals of the kingdom animalia have organ-system level of organization.
 - (13) Animal body plans: It have three types of body plans:
- (i) Cell aggregate plan: The body consists of a cluster or aggregation of cells which have rudimentary differentiation but are not organized into tissues or organs. It is found in sponges.
- (ii) **Blind sac plan:** The body has a single cavity which function as digestive tract and coelom both and have one opening to the outside. The single opening functions as both mouth for ingestion (intake of food) and anus for egestion (undigested waste is passed out) such a digestive tract is called incomplete animals having blind sac body plan show tissue grade body organisation. The cells are specialized, organised into tissues and show division of labour. It is found in coelenterates and flatworms.
- (iii) **Tube-within-a-Tube plan**: The body has two tubes, one formed by the body wall and the second formed within it by the digestive tract. Digestive tract is a continuous tube-like structure that has two opening, a mouth for ingestion and anus for egestion such a digestive tract is called complete. In between two tubes is present coelom in which are present a number of organs. Food is digested and absorbed in the digestive tract. This type of body plan is found in Aschelminthes upto chordates.

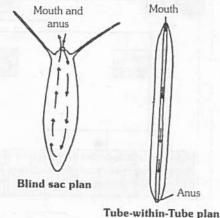

Fig: 1.7-1 Types of body plan

- (14) **Animal symmetry**: Body symmetry is the similarity of parts in different regions and directions of the body. When the body is not divisible into equal halves by any plane it is called asymmetrical or asymmetric as found in *Amoeba* and some sponges. An animal is said to be symmetrical if its body is divisible into equal halves by one or more planes. Four types of symmetry found in animals are —
- (i) **Spherical symmetry**: In this type of symmetry, any plane passing through the centre divides the body into equivalent or mirrored, halves. It is found in animals whose body resembles a sphere. e.g., Protozoans such as *Volvox*, *Heliozoa*, *Radiolaria*.

- (ii) Radial symmetry: In this type of symmetry, a number of similar parts radiate out from a central axis. The body of the individual can be divided into equal halves by any plane passing through the centre from top to bottom. This type of symmetry is found in some sponges (Sycon), coelenterates (e.g., Hydra, jelly fish), echinoderms (e.g., star fish).
- (iii) Biradial symmetry: In this type of symmetry, only two planes passing through the longitudinal axis. The body can be divided into two similar halves by one or two vertical planes only. This type of symmetry is found in sea walnuts (phylum ctenophora) and sea anemones (Anthozoa). The animals which show radial and biradial symmetry have oral and aboral sides. The oral sides is that which has mouth, whereas the aboral side is one which is opposite to oral side.
- (iv) Bilateral symmetry: In this type of symmetry, the body can be divided into two equal halves by a median longitudinal or sagittal plan only. The appearance of bilateral symmetry in animal evolution was a major advancement, because bilateral animals are much better fitted for directional (forward) movement than in radially symmetrical animals. This type of symmetry is found in many invertebrates and all vertebrates.

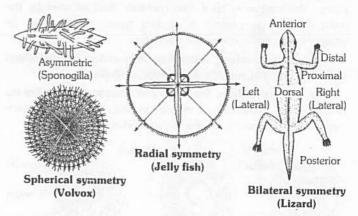

Fig: 1.7-2 Types of symmetry

- (15) **Germ layers**: They are primary layers of cells which differentiate in the animal embryos at the gastrulation stage. The germ layers give rise to all the tissues/organs of the fully formed individual. The embryos of poriferans and coelenterates have two germ layers, the ectoderm and endoderm. These animals are called diploblastic. The embryos of all other animals (from phylum Platyhelminthes to phylum Chordata) have three layers the ectoderm, mesoderm and endoderm. These animals are called triploblastic animals.
- (16) **Segmentation**: Segmentation is a type of body form having a linear sequence of units of segments possessing a similar or modified structure. It occurs in three animal phyla–Annelida, Arthropoda and Chordata.
- (17) **Metameric segmentation** (True metamerism or True segmentation): It is a type of segmentation where external divisions correspond to internal divisions. The body is often divided both externally and internally into a number of segments (metameres) e.g., annelids. Segmentation is mostly external in arthropods and mainly internal in man and other chordates (vertebrae, body muscles, some blood vessels and nerves).

- (18) **Pseudometamerism (False segmentation)**: It is found in tapeworms. In tapeworms, the proglottides (segments of tapeworms) are budded off from the neck, hence this segmentation is called pseudometamerism (pseudosegmentation). It differs from true segmentation of embryonic origin as found in annelids, arthropods and chordates.
- (19) Body cavity or Coelom: A body cavity or coelom is a fluid-filled space between the gut and the outer body wall of an animal. It contains the major internal organs.
- (i) Accelomates: The animals which do not have coelom are called accelomates e.g. sponges, coelenterates, ctenophorans and flat worms.
- (ii) Pseudocoelomates: The animals which have body cavity, called pseudocoel (false coelom) derived from blastocoel of the embryo are called pseudocoelomates. Round worms (Nemathelminthes) are psuedocoelomates.
- (iii) Eucoelomates (Coelomates): The animal which possess true coelom are called eucoelomates or coelomates. The true coelom is a body cavity which arises as a cavity in embryonic mesoderm. In this case, the mesoderm of the embryo provides a cellular lining, called coelomic epithelium or peritoneum, to the cavity. The coelom is filled with coelomic fluid secreted by the peritoneum. True coelom is of two types; schizocoelom or schizocoel and enterocoelom or enterocoel.
- (a) Schizocoelom. It develops as a split in the mesoderm sheet. It is found in annelids, arthropods, molluscs.
- **(b) Enterocoelom.** The mesoderm arises from the wall of the embryonic gut archentron or enteron as hollow outgrowths which form this type of coelom. It occurs in echinoderms and chordates.

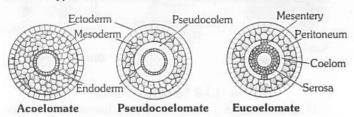

Fig: 1.7-3 Different types of coelom

Schizocoelous Blastocoel (Fluid filled) Endoderm Archenteron (Embryonic gut) Blastopore mesoderm cells Blastopore mesoderm coelom

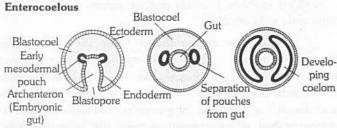

Fig: 1.7-4 Two different types of coelom formation

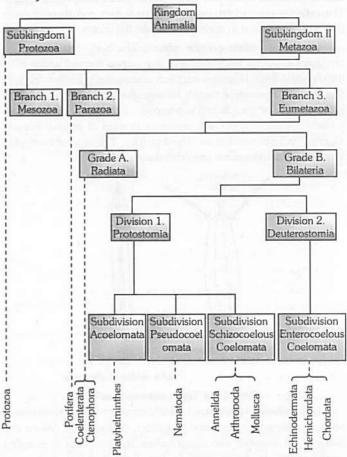

- (iv) **Haemocoelomates**: The primary body cavity or blastocoel persists to some extent in many animals either enclosed within narrow blood vessels as in annelids or open as blood-containing space called a haemocoel and such animals are called haemocoelomates. Haemocoels occur in Mollusca and Arthropoda.
- (20) **Protostomes and Deuterostomes**: The terms protostome and deuterostome denote the differences in the embryonic origin of the mouth.

In protostomes (first mouth) the mouth forms from the first opening of the embryo namely blastopore, the opening from outside into the archenteron, cleavage is determinate and spiral e.g. Platyhelminthes, Aschelminthes, Annelida, Arthropoda and Mollusca.

In deuterostomes (second mouth) the mouth never develops from the blastopore, although the blastopore may give rise to the anus cleavage which is indeterminate and radial. e.g. Echinodermata and chordata.

Outline classification of animal kingdom

The animal kingdom is subdivided into two sub-kingdoms, namely Protozoa and Metazoa.

Subkingdom 1. Protozoa : It includes microscopic, unicellular animals. It contains a single Phylum called protozoa. e.g. *Euglena*, *Amoeba*, *Paramecium* etc.

Subkingdom 2. Metazoa : This subkingdom includes multicellular animals. e.g. Porifera to Chordata. The subkingdom Metazoa is divided into three branches, namely Mesozoa, Parazoa and Eumetazoa.

Branch 1. Mesozoa: It is intermediate between Protozoa and Metazoa. It includes endoparasitic animals. e.g. Dicyema, Rhopalura etc.

Branch 2. Parazoa: It includes sponges.

Branch 3. Eumetazoa : It includes true multicellular organisms. They have tissue organ and organ system grade of organization. e.g. Coelenterata to Chordata. Eumetazoa is further divided into two grades, namely Radiata and Bilateria.

Grade A. Radiata: It includes radially symmetrical animals. e.g. Coelenterata.

Grade B. Bilateria: It includes bilaterally symmetrical animals, e.g. Platyhelminthes to Chordata. The grade Bilateria is further divided into two divisions namely proterostomia and deuterostomia

Division 1. Protostomia: In this group of animals, the blastopore develops into the mouth. It is further divided into 3 subdivision.

Subdivision 1. Acoelomata: In this group of animals, a coelom (Cavity lying between the gut and the body wall) is absent. e.g. Platuhelminthes

Subdivision 2. Pseudocoelomata: In this group of animals, a false coelom (cavity not lined with coelomic epithelium) is present. e.g. Aschelminthes or Nematoda.

Subdivision 3. Schizocoelous Coelomata: In this group, a true coelom is present. e.g. Annelida to chordata.

Division 2. Deuterostomia: In this group of animals, the blastopore develops into the anus. It consist of one subdivision.

Subdivision Enterocoelous coelomata: Coelom is enterocoel which originates as pouches of embryonic gut (archenteron)

Characters of Non Chordata (Invertebrates): The animals which lack vertebral coloumn are called invertebrates. e.g. Amoeba, sponges, Hydra, worms, insects, etc., Invertebrates are characterised by the following salient features -

- (1) The vertebral column is absent.
- (2) The nerve cord is solid in nature.
- (3) The nerve cord is present on the ventral side and never on the dorsal side.
- (4) When alimentary canal is present, it lies dorsal to the nerve cord.
- (5) Invertebrates may be acoelomate or pseudocoelomate or true coelomate
- (6) They have either asymmetry or radial symmetry or bilateral symmetry.
 - (7) The circulatory system is open type or closed type.
 - (8) They exhibit all possible types of reproduction.

The invertebrates are grouped into about 30 phyla. These phyla are of two types, namely minor phyla and major phyla.

Minor phyla: (1) Mesozoa (2) Nemertinea (3) Endoprocta (4) Acanthocephala (5) Rotifera (6) Gastrotricha (7) Kinorhyncha

- (8) Nematomorpha (9) Ectoprocta (10) Brachiopods (11) Phoronida
- (12) Chaetognatha (13) Priapulida (14) Sipunculida (15) Echiuroidea

(16) Pogonophora etc.

Table: 1.7-1 Major phyla: It include following phylum

Phylum	Some representatives	Existing species
Porifera	Sponges	5,000
Cnidaria	Hydrozoans, jellyfishes, corals, sea anemones	9,000
Ctenophora	Venus's girdle	100
Platyhelminthes	Turbellarians, flukes, tapeworm	13,000
Nemathelminthes	Pinworms, hookworms	15,000
Annelida	Polychaetes, earthworms, leeches	9,000
Mollusca	Snails, slugs, clams, squids, octopuses	60,000
Arthropoda	Crustaceans, spiders, insects	900,000
Echinodermata	Sea, stars, sea urchins	6,000
Chordata	Protochordates (nonverte- chordates), vertebrates Fishes	2,100
		25,600
	Amphibians	3,000
	Reptiles	6,000
	Birds	9,000
	Mammals	4,000

Phylum Porifera: The sponges (pore bearing animals)

(Gk. Porus = Pore; ferre = To bear)

Brief History: Robert Grant (1825) finally proved that sponges are animals, and coined the name 'Porifera' for these. Schulze (1878), Butschli (1884), Sollas (1884) and Delage (1898) separated sponges from other metazoans on the basis of embryological studies, and suggested a separate group, "Parazoa" for these.

General Characters

Gland cells

- (1) All the sponges are aquatic, sedentary, asymmetrical or radially symmetrical. These are the first multicellular organisms and have cellular grade of organization.
- (2) They are diploblastic. Ectoderm is formed by pinacocyte and endoderm is formed by choanocyte. Both layers are called pinachoderm and choanoderm. A gelatinous noncellular mesenchyme is present in between them.

Choanocytes (flagellated collar cells) are present only in sponges.

- (3) Mesenchyme contains free amoebocytes and skeletal elements.
 - (4) Different types of amoebocytes are :

Archaeocytes : undifferentiated totipotent cells.

Chromocytes : with pigment granules. Thesocytes : with reserve food granules.

Myocytes : highly contractile, spindle-shaped cells.

Trophocytes : supply nutrients to developing cells (nurse cells)

: secrete slimy substance.

: develop from archaeocytes only during Sex cells

breeding season.

- (5) The body is perforated by numerous minute pores called ostia.
- (6) The ostia open into a large cavity called spongocoel or paragastric cavity.
- (7) The spongocoel opens to the outside by a large opening called osculum.
- (8) Sponges have a canal system and they need a continuous current of water flowing through their bodies for respiration, excretion, nutrition and reproduction.
- (9) Different types of canal system in sponges are asconoid, syconoid and leuconoid.
- (10) The simplest type of canal system in porifera is asconoid type.

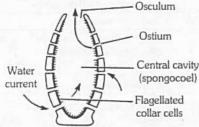

Fig: 1.7-5 Asconoid Type of canal system

(11) The course taken by the water current way be shown as under -

Ingressing water Ostia Spongocoel Osculum To outside

- (12) The sponges possess an endoskeleton in the form of calcareous spicules, siliceous spicules and spongin fibres.
 - (13) Excretion and respiration occur by diffusion.
- (14) They have greater power of regeneration due to totipotent archaeocytes.
- (15) Digestion in sponges is intracellular like protozoans. Digestion takes place in the choanocytes.
- (16) All sponges are hermaphrodite, reproduction takes place by asexual or sexual methods.
- (17) Gemmules are internal buds containing archaeocytes, mostly found in fresh water sponges, concerned with asexual reproduction.
- (18) Development is indirect or direct. The common larval forms are parenchymula (*leucosolenia* and *Clathrina*), amphiblastula (*Sycon*), etc.

Classification of porifera: On the basis of types of endoskeleton, phylum porifera is divisible into three classes

Osculum

Oscular

fringe

Ostia

Base

Fig: 1.7-6 Sycon

Cylinders

Class 1. Calcarea or Calcispongiae

- (1) Skeleton is formed of Calcareous spicules.
 - (2) Radially symmetrical.
- (3) Choanocyte cells are large and conspicuous.
- (4) Canal system asconoid (ascon) or syconoid (sycon) type.
- (5) These are also known as limy sponges.

Examples: Clathrina, Leucosolenia, Sycon, Grantia, etc.,

 \square Leucosolenia is a smallest sponge with asconoid type of canal system.

Class 2. Hexactinellida Or Hyalospongiae

- (1) Skeleton is formed of six rayed triaxon, siliceous spicules,
- (2) Canal system is branched or unbranched.
- (3) Radially symmetrical.
- (4) These are also known as glass sponges.

Examples: Pheronema, Hyalonema, Euplectella, etc.,

☐ Euplectella is the sponge which is given as a Gift in Japan and known as "venus flower basket". It show commensalism with shrimps of the genus spongicola, 'life upto death'.

Class 3. Demospongia

- (1) Skeleton either absent or present. When present it is either formed of spongin fibres or combination of spongin fibres and siliceous spicules.
 - (2) The siliceous spicules when present are never six rayed.
- (3) The canal system is complicated Rhagon type or leuconoid type.
 - (4) Rhagon larva is formed.
 - (5) These sponges are of great economic importance.

Examples : Cliona, Spongilla, Chalina, Euspongia, Hippospongia, Oscarella, etc.,

- ☐ Spongilla is a fresh water sponge.
- Cliona is harmful to oyster industry.
- Spheclospongia is the largest sponge.

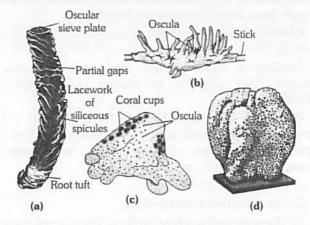

Fig: 1.7-7 Some economically important – sponges
(a) Euplectella (b) Spongilla
(c) Cliona (d) Euspongia

Table: 1.7-2 Common Names

	-	
Scypha (= Sycon)	-	Urn sponge, Crown sponge
Euplectella	-	Venus' flower-basket
Phyllospongia	-	Leaf sponge
Pheronema	-	Bowl sponge
Hyalonema	-	Glass-rope sponge
Cliona	-	Boring sponge
Chalina	-	Mermaids gloves (Dead man's fingers)
Spongilla	-	Freshwater sponge
Euspongia	-	Bath sponge, Horse sponge
Poterion	-	Neptune's goblet
Hippospongia	_	Horse sponge
Hircinia	-	Horny sponge

Phylum-Cnidaria (Coelenterata)

(Gk. knide = nettle or stinging cell)

Brief History: Peyssonel (1723) and Trembley (1744) proved these to be animals. Hence, Linnaeus (1758), Cuvier (1796) and Lamarck (1801) included these under 'Zoophyta', together with sponges. Leuckart (1847) included sponges and cnidarians under his phylum Coelenterata. Finally, Hatschek (1888) divided "Coelenterata" into three phyla–Spongiaria (= Porifera), Cnidaria and Ctenophora.

General characters

- Coelenterates are radially symmetrical animals with tissue grade of body organization.
 - (2) All the members of this phylum are aquatic, mostly marine.
 - (3) They are solitary or colonial, sedentary or free swimming.
- (4) The body wall is diploblastic. It is made up of two layers of cells, namely the ectoderm and the endoderm with a non-cellular layer called mesogloea in between.
- (5) Cnidarians exhibit dimorphism with polypoid and medusoid stage (Metagenesis or alternation of generation).
- (6) Asexual phase is generally polyp and sexual phase is medusa.
 - (7) Coelom is absent; Hence coelenterates are acoelomate animals.
- (8) A gastrovascular cavity or coelenteron is present. It can be compared to the gut of higher animals.
- (9) Mouth is present but anus is absent (blind-sac body plan). Mouth is surrounded by tentacles.
- (10) The most characteristic feature of coelenterates is the presence of nematocysts or stinging cells.
 - (11) Digestion is extracellular as well as intracellular.
- (12) Respiratory, excretory and circulatory system are absent. Oxygen is carried to various tissues through general body surface by diffusion.
- (13) Primitive nervous system with synaptic or non-synaptic nerve net but no brain.
- (14) Sense organs are statocysts (tentaculocysts), ocelli and olfactory pits.
 - (15) Reproduction both asexual and sexual.
- (16) Development is indirect as there are one or two larval forms, Planula (Obelia) and Ephyra (Aurelia).

Classification of coelenterata: On the basis of the dominance of medusoid or polypoid phase in the life cycle, phylum coelenterata is divided into three classes —

Class 1. Hydrozoa (Gr. hydros, water, zoios, animal)

- Hydrozoa are solitary and fresh water or mostly colonial and marine, sessile and free-swimming forms.
 - (2) They exhibit tetramerous or polymerous radial symmetry.
- (3) Body wall consists of an outer ectoderm and an inner endoderm separated by a non-cellular gelatinous mesogloea.

- (4) Gastrovascular cavity is without stomodaeum, septa or nematocysts bearing gastric filament.
- (5) Skeleton or horny structure is horny perisarc in some forms, while coenosarc secretes a skeleton of calcium carbonate forming massive stony structure or coral in other forms.
- (6) They exhibit polymorphism. There are two main types of zooids, the polyp and medusa. Medusa is provided with true muscular velum.
 - (7) Many hydrozoa exhibit alternation of generation.
- (8) Reproductive products of sex cells are usually ectodermal in origin and discharged externally.
 - (9) Cleavage is holoblastic, embryo ciliated planula.
 - (10) Both polypoid and medusoid stages are present.

Examples : Hydra, Tubularia, Bougainvillea, Hydractinia, Eudendrium, Pennaria, Obelia, Sertularia, Plumularia, Companularia, Millepora, Stylaster, Geryonia, Physalia, Porpita, Velella, Pericolpa, Periphylla, Cynaea, Rhizostoma or Pilema Cassiopeia, etc.,

- Obelia is trimorphic and marine colony.
- ☐ Hydranth of *obelia* bears twenty four (24) tentacles while medusa bears sixteen (16) tentacles in addition to tentaculocysts.

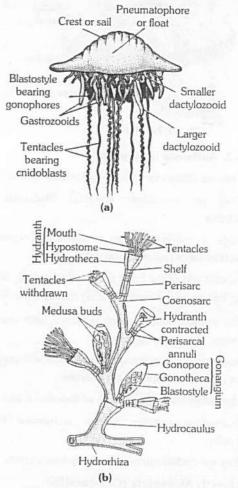

Fig: 1.7-8 (a) Physalia (b) Obelia

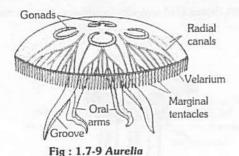

Class 2. Scyphozoa (Gr. skyphos, cup, zoios, animal)

- (1) Scyphozoa include large jellyfishes or true medusae.
- (2) They are exclusively marine.
- (3) Medusae are large, bell or umbrella-shaped and without true velum. They are free swimming or attached by an aboral stalk.
 - (4) Marginal sense organs are tentaculocysts.
- (5) Polypoid generation is absent or represented by small polyp, the scyphistoma which gives rise to medusae by strobilization or transverse fission.
- (6) Gastrovascular system is without stomodaeum, with gastric filaments and it may or may not be divided into four inter-radial pockets by septa.
 - (7) Mesogloea is usually cellular.
- (8) Gonads are endodermal and the sex cells are discharged into the stomach.

Examples : Lucernaria, Haliclysus, Aurelia, Rhizostoma, Charybdea, Periphylla, Chrysaora.

☐ Rhizostoma is a polystomous scyphozoan with many mouth bearing structures called scapuletes.

Class 3. Anthozoa (Actinozoa) .

- (1) These are solitary or colonial exclusively marine forms.
- (2) They are exclusively polypoid. Medusoid stage is altogether absent.
- (3) Body is cylindrical with hexamerous, octomerous or polymerous biradial or radiobilateral symmetry.
- (4) The oral end of the body is expanded radially into an oral disc bearing hollow tentacles surrounding the mouth in the centre.
- (5) The stomodaeum is often provided with one or more ciliated grooves, the siphonoglyphs.
- (6) Gastrovascular cavity is divided into compartments by complete or incomplete septa or mesenteries.
 - (7) Mesenteries bear nematocysts at their free edges.
- (8) Mesogloea contains fibrous connective tissue and amoeboid cells.
 - (9) They are exclusively marine, many forms corals.

Subclass 1. Alcyonaria (Octocorallia)

(1) These are colonial marine forms.

- (2) Polyps are long or short cylinders terminating orally into a flat circular oral disc having the oval or elongated mouth in the centre.
 - (3) Polyps always bear eight pinnate, hollow tentacles.
 - (4) Eight complete mesenteries are present.
 - (5) Single ventral siphonoglyph is present
- (6) Endoskeleton is the product of mesogloeal cells comprised of calcareous spicules either calcareous or horny in nature.
 - (7) Polyps are dimorphic in some forms.

Examples : Tubipora, Clavularia, Alcyonium, Xenia, Heliopora, Gorgonia, Corallium, Testudo, etc.,

☐ Corals form rocks in the sea, called the coral reefs. The largest coral reef is the great barrier reef which is 1200 miles long and surrounds Australia complete.

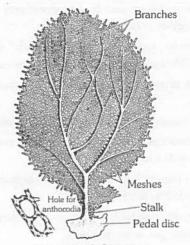

Fig: 1.7-10 Gorgonia Subclass 2. Zoantharia (Hexacorallia)

- (1) These are solitary or colonial marine forms.
- (2) Tentacles simple, rarely branched, hollow cone shaped, numerous arranged in the multiple of five and six but never eight.
- (3) Mesenteries are numerous arranged in the multiple of five or six, may be complete or incomplete.
- Crown of Oral disc Mouth tentacles.

 Collar

 Column or scapus

 Limbus

 Pedal

Fig: 1.7-11 Metridium

- (4) Two siphonoglyphs are commonly present.
- (5) Endoskeleton when present is calcareous, derived from ectoderm.
 - (6) Polyps are usually monomorphic.

Examples: Actinia, Metridium, Adamsia, Edwardsia, Astraea, Fungia, Zoanthus, Antipathes, Aeropora or Madrepora, etc.

Metridium shows commensalism with Eupagurus.

Some representative animals

Hydra

- (1) Hydra belongs to class Hydrozoa of phylum coelenterata.
- (2) Trembly (1744), a Swiss biologist discovered Hydra.

Linnaeus (1758) gave the name *Hydra*, a Greek word, means 'Water serpent' based on its ability to regenerate its lost parts.

- (3) Hydra is a solitary polyp found in freshwater (stagnant). Among coelenterates Hydra is one of the smallest polyps.
- (4) It is colourless carnivorous coelenterate having radial symmetry.
- (5) Hydra is diploblastic and has tissue grade of organization with division of labour on morphological basis.
- (6) Chlorohydra viridissima is called green hydra. It is green because of symbiotic association with a unicellular green algae Chlorella vulgaris. Algae live in the musculonutritive cells of Hydra.
- (7) Hydra has a cylindrical body with 6-10 hollow tentacles. It helps in locomotion and food capture, so analogous (correspond functionally) to pseudopodia of Amoeba.
- (8) Mouth is situated on a manubrium or hypostome. It is most sensitive in the body. *Hydra* has no anus.
- (9) The body wall of Hydra consists of ectoderm and endoderm, in between a thin, delicate, transparent and noncellular mesogloea.
- (10) Ectoderm consists of epithelio-muscular cells, sensory cells, nerve cells, interstitial cells (totipotent) and stinging cells or cnidocytes having nematocysts.
- (11) Inner gastrodermis has nutritive muscular cells, gland cells, nerve cells, sensory and interstitial cells. Nutritive muscular cells bear both flagella and pseudopodia.
- (12) The contraction of muscle fibres in endothelio-muscular cells or nutritive muscle cells reduces the diameter of the body and works like circular muscles.

- (13) Mesogloea is thin and acellular consisting of a proteinaceous matrix and it can be crossed by interstitial cells. It is neither cellular nor fibrous.
- (14) Cnidoblasts or nematocysts are derived from interstitial cells of epidermis.
- (15) Body cavity of *Hydra* is called coelenteron or gastrovascular cavity. Coelenteron serves the double purpose of digestion and circulation.
- (16) Nematocysts are found only in epidermis mainly on tentacles. Nematocysts are also known as "independent effectors".
- (17) Hydra paralyses its prey by nematocyst. If all nematocysts of a Hydra are removed it would affect its capacity to capture prey.
- (18) Nematocyst plays an important role in locomotion, food capture both offence and defence.
- (19) Hydra has four types of nematocysts: Penetrants or stenoteles (largest), valvents (smallest), stereoline glutinants (small, atrichous) and streptoline glutinants (large holotrichous)
- (20) Digestion in *Hydra* is first extracellular (in gastrovascular cavity) and then intracellular (in endoderm cells).
- (21) Hydra has no specialized cells for respiration, it respires by means of general body surface.
- (22) Nitrogenous excretory product in *Hydra* is ammonia and it is removed through general body surface.
- (23) Hydra possesses a very primitive nervous system consisting of a synaptic network of bipolar and multipolar nerve cells, but brain is absent.
- (24) *Hydra* is monoecious or dioecious. Most species are dioecious or unisexual. Bisexual species of *Hydra* are protandrous, so avoid self-fertilization.
- (25) Hydra reproduces asexually by exogenous budding, a type of vegetative propagation, and sexually by formation of gametes. Hydra reproduces by budding when plenty of food is available.

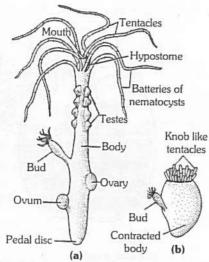

Fig: 1.7-12 Hydra (a) Expanded body with bud and gonads (b) Contracted body bearing bud

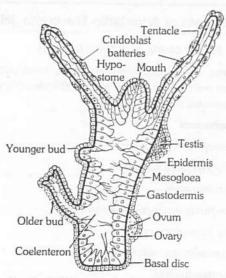

Fig: 1.7-13 Longitudinal section of entire animal

- (26) Hydra normally possesses a single ovary (in aboral region) and many testes (in oral region).
- (27) Fertilization occurs externally on the body by the entry of sperm into ovum.
- (28) The developing embryo in *Hydra* drops down from the body of parent after the formation of gastrula.
- (29) In the development of *Hydra* there is no moulting or ecdusis.
- (30) No free larval stage (only a planula like stage) occurs in *Hydra*.
- (31) Hydra has great regeneration capacities. A piece of Hydra will regenerate into a full Hydra if it contains a part of epidermis and gastrodermis and size is not less than 1/6 mm in diameter.

Table: 1.7-3 Common Names

Obelia	-	Sea fur
Millipora	-	Stinging coral
Physalia	=	Portuguese man-of-war
Velella	-	Little sail, Purple sail
Chiropsalmus	-	Sea wasp
Aurelia	-	Jellyfish
Metridium	-	Sea anemone
Adamsia	-	Sea anemone
Pennatula	_	Sea pen
Corallium	-	Precious red coral
Meandrina	-	Brain coral
Tubipora	_	Organ pipe coral
Heliopora	-	Blue coral
Astraea	_	Stony coral
Virgularia	_	Walking stick
Fungia	-	Mushroom coral
Alcyonium	-	Dead man's finger

Phylum-Ctenophora or Acnidaria- The comb Jellies

(Gk. kteis = comb; pherein = To bear)

Brief History: The ctenophores as a distinct group were first recognized by *Escscholtz* (1829). *Hatschek* (1889) placed it under a separate phylum called ctenophora.

General characters

- (1) All the ctenophores are marine.
- (2) They are solitary and pelagic.
- (3) They are transparent.
- (4) They have tissue-grade of organization.
- (5) They have biradial symmetry.
- (6) They are acoelomate animals.
- (7) They are unsegmented.
- (8) Their body-wall is diploblastic.
- (9) The mesogloea contains cells.

- (10) Nematocysts are absent.
- (11) Special adhesive cells called colloblasts are present in all ctenophores.
 - (12) The gastrovascular system is well developed.
 - (13) Two anal openings are present.
 - (14) Skeletal system is absent.
 - (15) Excretion and respiration are carried out by diffusion.
 - (16) The nervous system is in the form of nerve net.
 - (17) An aboral sense organ is present in the form of statocyst.
 - (18) Cilia are used for locomotion.
 - (19) They are hermaphrodites.
 - (20) Development is indirect. It includes a cydippid larva.

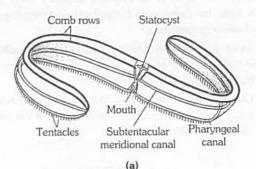

Classification of Ctenophora

Class 1. Tentaculata

- (1) The body is simple, rounded or oval or ribbon-like.
- (2) Two long aboral tentacles are present.
- (3) Mouth is narrow and pharynx is small.

Examples : Pleurobrachia, Hormiphora, Mertensia Mnemiopsis, Bolinopsis, Velamen, Cestum, Ctenoplana, Coeloplana, etc.

- ☐ Cestum is commonly called "venus's girdle".
- ☐ Ctenoplana shows commensallism with Alcyonea.

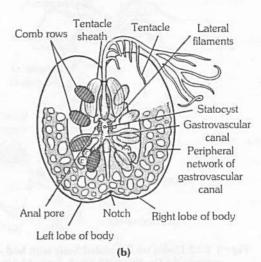

Fig: 1.7-14 (a) Velamen (b) Ctenoplana

Class 2. Nuda

- (1) Body is large thimble-shaped or conical.
- (2) Tentacles are absent.
- (3) Mouth is wide and pharynx is large.
- (4) The meridional vessels are produced into a complex system of anastomosing branches.

Example: Beroe

☐ Beroe is commonly called "Swimming eye of cat".

Phylum Platyhelminthes: The flat worms

(Gk. platys = broad or flat; helmin = worm)

Brief History: Aristotle mentioned tapeworms, but scientific studies of flatworms began only in the 18th century. It was Gegenbaur (1859) who placed these in a separate group and suggested the present name of the phylum.

General Characters

- (1) They are dorso-ventrally flattened like a leaf.
- (2) They show organ grade of organization.
- (3) They are acoelomate animals. The cavity in platyhelminthes is filled with mesenchyme or parenchyma.
- (4) They are triploblastic animals. The cells of the body wall are arranged in three layers. They are the ectoderm, the mesoderm and the endoderm.
- (5) They are bilaterally symmetrical animals. The body of the animal can be divided into two equal similar halves through only one plane. Animals with this symmetry have definite polarity of anterior and posterior ends.
- (6) Some members have segmented body. The segmentation in platyhelminthes is called pseudometamerism.
- (7) Many of the parenchyma cells give rise to muscle fibres. The muscle fibres are arranged in circular, longitudinal and vertical layers.
- (8) The digestive system is completely absent from Cestoda and Acoela. The alimentary canal is branched in Turbellarians. The anus is absent from them.
- (9) The respiratory organs are absent. In parasites respiration is anaerobic.
 - (10) There is no circulatory system.
- (11) The excretory system is formed of protonephridia (flame cells or solenocytes).
 - (12) Anus is absent like coelenterates, with blind sac body plan.
- (13) The nervous system is well developed. It is formed of longitudinal nerve cords with ganglia. A pair of anterior ganglia form the brain. The longitudinal nerve cords are connected together by transverse connectives.
- (14) They are hermaphrodites, i.e., both male and female reproductive organs are present in the same animal.

- (15) Fertilization is internal in them. Self or cross fertilization takes place in them.
- (16) Their development is direct or indirect. Endoparasites show usually indirect development with many larval stages. Their life cycle is completed in one or two hosts.
- (17) They are free living or parasitic. In parasitic worms adhesive organs like hooks, spines, suckers and adhesive secretions are present.

Classification of platyhelminthes: On the basis of digestive tract and free living or parasitic nature phylum platyhelminthes has been divided into three classes –

Class 1. Turbellaria (L. turbella, a string)

- (1) Most of the turbellarians are free living but some of them are ecto commensal or parasitic, commonly called planarians or flat worms.
- (2) The body epidermis is either cellular or syncytial and covered with cilia. Epidermis contains rhabdites.
 - (3) Segmentation is absent.
 - (4) Digestive system is present except in a few.
 - (5) Suckers are absent.
 - (6) Life cycle is simple, development direct.

Example: Dugesia, Notoplana, Bipalium, Thysanozoon, etc.

☐ Bipalium is the only terrestrial planarian.

Class 2. Trematoda (Gr. trema, hole)

- (1) Ecto or endoparasites of vertebrates; commonly called flukes.
- (2) Body mostly oval, unsegmented.
- (3) Body wall without cilia, but covered by a thick, resistant, syncytial tegument.
- (4) Suckers, and often hooks and spines, present for attachment to host tissues.
 - (5) Sense organs usually absent in adults.
- (6) Digestive system well developed with terminal mouth, but no anus.
 - (7) Mostly hermaphrodite. Life cycle simple or complicated.

Examples: Polystomum, Fasciola, Schistosoma (blood fluke of man and other mammals), Opisthorchis, etc.

Opisthorchis sinensis is commonly known as chinese liver fluke of man.

Class 3. Cestoda

- All endoparasites. Mostly in alimentary canal of vertebrates; commonly called tapeworms.
- (2) Body long and slender, tape-like, usually divided into small segments (= proglottids).
 - (3) Body wall non-ciliated, with a thick tegument.
 - (4) Anterior end with suckers and other attachment organs.
- (5) No mouth, digestive system absent, digested liquid food is absorbed from host tissues by diffusion through body wall.
 - (6) Sense organs absent.
- (7) Each proglottid contains one or two complete sets of hermaphrodite (bisexual) reproductive organs.

(8) Life-cycle usually complicated with alternation of hosts. Embryo hooked.

Examples – Taenia, Echinococcus, Hymenolepsis, Diphyllobothrium, Echinococcus, Dipylidium.

- ☐ Hymenolepsis is dwarf tapeworm. It is monogenetic tapeworm of man.
 - □ Dipylidium is dog tapeworm.
 - □ Diphyllobothrium is the largest tapeworms.
- ☐ Echinococcus is also called hydatid worm. Its hydatid cyst shows exogenous as well as endogenous budding. Parasite of small intestine of dogs, cats, etc. It has only 3-4 proglottids.

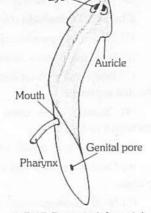

Some representative animals

Planaria

- Dugesia (Planaria) is found commonly in freshwater ponds, lakes, streams and shallow rivers.
 - (2) Planaria are gregarious, i.e., they live in groups.
 - (3) The head bears a pair of lateral projections called auricles.

(4) The mouth opens on the mid ventral surface near the middle of the animal.

- (5) The pharynx is a tubular structure that can be everted beyond the mouth.
- (6) Planarians have remarkable power of regeneration.
- (7) If an individual is cut transversely into two parts, the anterior fragment will regenerate a new tail and a posterior piece will develop a new head.

(8) Neoblast cells found in Fig: 1.7-15 Dugesia (planaria) planarians which is help in regeneration.

Fasciola hepatica

- (1) Fasciola hepatica, commonly known as sheep liver fluke is an endoparasite of sheep which reside in the liver and bile duct.
- (2) The liver fluke has a dorsoventrally flat, unsegmented body with two suckers, oral sucker (anterior sucker) and acetabulum (ventral sucker).
- (3) Liver fluke is covered with a cuticle, lacks ciliated epidermis.
- (4) There are three permanent apertures on the body-mouth (surrounded by oral sucker), genital pore (located between the two suckers), excretory pore (At the extreme posterior end). During breeding season a temporary opening, the aperture of laurer's canal is also developed. Laurer's canal is present between the genital aperture and the uterus.

- (5) Suctorial pharynx with bifurcated intestine. A large number of caeca or diverticulae arise from each branch of intestine.
- (6) Digestion is holozoic.

 The parasite obtains nourishment from bile, blood, lymph and epithelial cells.
 - (7) Respiration is anaerobic.
- (8) Excretion occurs with the help of flame cells.
- (9) Fasciola is a digenetic endoparasite. Its primary host is sheep causing 'liver rot' and the secondary or intermediate host is the snail of genus Limnaea and Planorbis.

Mouth

Oral or anterior

sucker

Acetabulum

Gonopore

- (11) Fertilization is internal. Cross fertilization commonly occurs.
- (12) Different larval stages of Fasciola hepatica according to development sequence are: miracidium-sporocyst-Redia-Cercaria-Metacercaria.
- (13) Stage in the life cycle of Fasciola when it infects intermediate host (snail) is miracidium and primary host is metacercaria.
- (14) Miracidium and cercaria larva are free swimming form in water. Redia and sporocyst are formed in snail.
- (15) Fasciola exhibits both alternation of generation and alternation of host.

Schistosoma

- (1) Schistosoma is commonly known as human blood fluke
- and it is found in the blood vesseles and hepatic portal system of man, cat, pig, dog, etc.
- (2) Phenomenon of sexual dimorphism occurs. Thus male and female are separate but they live in close association.
- (3) Male is flattened while female is slender. Both possess oral and ventral suckers.
- (4) The ventral folding from the male's body forms a groove known as 'Gynaecophoric canal' in which the female individual lives.

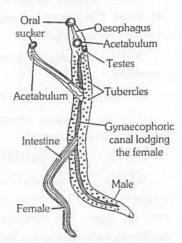

Fig: 1.7-17 Schistosoma both male and female

- (5) Blood fluke feeds on blood. It respires anaerobically. Excretion occurs with the help of flame cells.
- (6) Blood fluke is digenetic, primary host is man and secondary host is snail.
- (7) Fertilization is internal. After fertilization the egg develops into miracidium larva which is free swimming. Later on it penetrates snail body and get converted into cercaria larva. The cercaria infect man by penetrating his skin.
 - (8) Redia and metacercaria stage do not occurs in blood fluke.
 - (9) Blood fluke causes schistosomiasis or bilharzia.

Taenia solium

- (1) Taenia solium is commonly known as pork-tape-worm.
- (2) Adult tapeworm lives in the small intestine of man (primary host), larval stage in the secondary or intermediate host pig or cattle.
- (3) Taenia solium possesses elongated ribbon or tape like segmented body (pseudometamerism).
- (4) Body is divided into three parts, namely scolex, neck and strobila. Scolex has a rostellum bearing two circles of chitinous hooks and four suckers for holding onto the host. Neck is the region of proliferation of new proglottids. Strobila is long tapering part having large number of proglottids. Proglottids are of three types-young, mature and gravid.
- (5) Young or immature proglottids are behind neck without reproductive organs.
- (6) Mature proglottids are in the middle having reproductive organs, both male and female.
- (7) Gravid proglottids (rectangular in shape) are with branched uterus containing fertilized eggs.
 - (8) Apolysis is the process of separation of gravid proglottids.

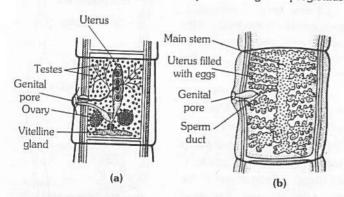

Fig: 1.7-18 (a) Mature proglottid, (b) Gravid proglotid

- (9) Body wall lacks a cellular epidermis. It consists of cuticle (parasitic adaptation), musculature and mesodermal tissue called parenchyma.
- (10) Digestive system is simple without alimentary canal. Food is absorbed through body surface.
 - (11) Respiration is anaerobic in Taenia solium.
 - (12) Flame-cells (solenocytes) are excretory in function.

- (13) All tapeworms are hermaphrodites, and a complete reproductive system occurs in each mature proglottid. Fertilization is internal, cross type within the same proglottid or between two proglottids of the same strobilla.
- (14) The fertilised eggs develop into an embryo that gets covered by a shell. The shelled embyros are called onchospheres. Secondary host pig acquires infection by ingesting the onchospheres. Hexacanth is developed in shell with six hooks.
- (15) Hexacanth stage is the infective stage to pig. In the stomach of pig, hexacanth will be released, it goes through blood circulation and on reaching muscles get encysted in the form of bladderworm (cysticercus). Human host gets infection by eating raw or poorly cooked 'measly pork'. Cysticercus is infective stage to man.
 - (16) Cysticerci in pig muscle can remain viable for several years.
- (17) Taenia saginata (Taeniarhynchus saginatus) is commonly known as 'the beef tapeworm'.
- (18) Like *Taenia solium*, it is digenetic, man is the primary host and cattle is the intermediate host.
- (19) It is also called 'unarmed tapeworm' because the scolex does not possess hooks.
- (20) During infection with taenia necrosis of brain and epilepsy may appear.
- (21) The disease caused by bladderworm is known as cysticercosis. Cysticercosis is more dangerous than taeniasis.

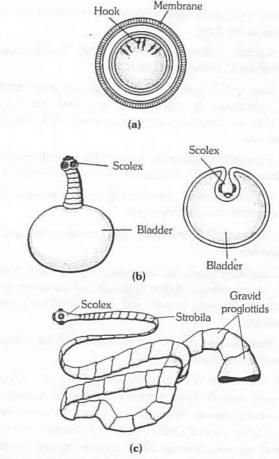

Fig: 1.7-19 Life cycle of *Taenia solium* (a) Onchosphere (b) Bladderworm (Cysticercus) (c) Adult tapeworm

Table: 1.7-4 Common Names

Fasciola hepatica	-	Sheep liver fluke
Fasciola gigantica	-	Cattle liver fluke
Schistosoma mansoni	-	Human blood fluke
Fasciolopsis buski	-	Intestinal fluke
Paragonimus westermani	-	Lung fluke
Taenia solium	-	Pork tapeworm
Taenia saginata	-	Beef tapeworm
Echinococcus granulosus	-	Dog tapeworm

Phylum Aschelminthes (Nemathelminthes)-The round worms

(Gk. nema = thread; helmin = worm)

Brief History: Ancient people were familiar with certain large-sized nematode parasites of domestic animals. Minute nematodes were discovered only after the invention of microscope. Linnaeus (1758) included these in "Vermes" Rudophi (1793, 1819) included these under "Nematoidea" Gegenbaur (1859) ultimately proposed "Nemathelminthes" for these.

General Characters

- (1) Many endoparasites of various animals and plants; others free-living and widely distributed in all sorts of water and damp soil.
- (2) Mostly minute or small; some large (1 mm to 25 cm); some upto several meters long.
- (3) Slender, cylindrical, elongated body usually tapering towards both ends, and unsegmented.
- (4) Body wall formed of a thick, tough and shiny cuticle, a syncytial hypodermis beneath cuticle, and innermost layer of peculiar, large and longitudinally extended muscle cells arranged in four quadrants.
- (5) Triploblastic, bilaterally symmetrical, pseudocoelomate, false coelom derived from embryonic blastocoel, unsegmented.
- (6) Straight alimentary tract terminal mouth and anus. These are first animals to have complete gut.
- (7) 'Tube within a tube body' plan, organ-system grade of body organization.
- (8) Circulatory system and respiratory organs absent. A simple excretory system consists of protonephridia, comparatively simpler or complicated sensory organs, and a well-developed nervous system present
- (9) Reproductive system well-developed. Usually unisexual with sexual dimorphism.
- (10) Many kinds of Nematodes are parasites of useful plants and domestic animals. Some of these are pathogenic to their hosts, causing serious diseases. Even man is a host for more than 50 species, of which Ascaris lumbricoides and Enterobius vermicularis (pin worm) are very common. Other common human nematodes are Wuchereria which causes Filaria, Trichinella causing trichinosis, and Ancylostoma causing hookworm disease.

Classification of Nemathelminthes: On basis of the presence or absence of some specialized sense organs and caudal glands, and characteristics of excretory system, nematodes are classified into two classes –

Class 1. Phasmidia or Secernentea or Rhabditea

- (1) Mostly parasitic.
- (2) Possess a pair of unicellular, pouch-like sense organs, called phasmids, near hind end of body.
- (3) Another pair of reduced, pore-like sense organs, called amphids, present near anterior end.
 - (4) Excretory system with paired lateral canals.
 - (5) Caudal glands absent.

Examples – Ascaris, Enterobius, Ancylostoma, Wuchereria, Trichuris, Trichinella, Dioctophyma, Rhabditis Necator, Gnathostoma, Dracunculus, Loa, etc.

Class 2. Aphasmidia or Adenophorea or Enoplea

- (1) Mostly small, free-living.
- (2) No phasmids.
- (3) Amphids spiral, cord like or disc like, seldom pore like.
- (4) No lateral excretory canals.
- (5) Caudal glands present.

Examples : Enoplus, Dorylaimus, Mermis, Halichoanolaimus, Monohystera, Desmoscolex, etc.

Some representative animals

Ascaris

- (1) Ascaris lumbricoides, the common roundworm belong to the class Rhabditea of the phylum Nemathelminthes. It is the most common endoparasite in the small intestine of human beings. It is monogenetic, i.e., without any secondary host. The worm is more common in children.

 Triradiate mouth
- (2) The body is elongated, unsegmented, cylindrical with tapering ends and four streakstwo lateral, one ventral and one dorsal.
- (3) Sexes are separate with sexual dimorphism. Male is smaller than female with curved tail, two penial setae (copulatory organs) and cloaca. Female is with straight posterior end of the body and posterior transverse anus and separate gonopore situated ventrally 1/3 from the anterior end. In both the excretory pore is situated midventrally, a little behind the mouth. Ventral surface of male

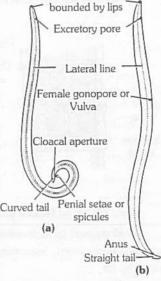

Fig: 1.7-20 Ascaris
(a) Male (b) Female

bears fifty pairs preanal and five pairs postanal papillae. These sensory papillae are absent in female.

- (4) Mouth both in male and female is terminal, triradiate surrounded by three denticulate lips. One median dorsal and two ventrolateral. Dorsal lip bears two sensory double papillae (tangoreceptors). Both sensory papillae and amphids (chemoreceptors) are present on ventrolateral lips.
- (5) Body wall consists of outer cuticle, middle epidermis and inner longitudinal muscle layer. Circular layer is absent. Cuticle is thick which protects the body of the parasite from mechanical injury and also resistant to action of digestive enzymes of the host. The epidermis is syncytial (coenocytic) with scattered nuclei and without partition walls.
- (6) The body cavity of Ascaris is pseudocoel formed by vacuoles originated from persistent embryonic blastocoel.
- (7) There is no alimentary canal and digestive gland. The parasite absorbs digested food of the host so their is no need of digestive organs. Absorption occurs through the general body surface. Salivary glands do not occurs in Ascaris.
 - (8) Respiratory system is absent, respiration is anaerobic.
- (9) Excretory system is H-shaped. It is consists of a single excretory cell or renette cell. Excretory products are ammonia and urea.
- (10) Sense organs are simple like labial papillae, cervical papillae, anal papillae, amphids and phasmids.
- (11) Ascaris is dioecious or unisexual. Testes is single and median, so male Ascaris is monarchic (monodelphic). Only anterior part of testis is functional, so testis (also ovary) is telogonic.
- (12) Ascaris sperm is peculiar without flagellum, tail less, asymmetrical and amoeboidal.
- (13) Female Ascaris has paired ovaries so female Ascaris is didelphic.
- (14) Copulation occurs in the intestine of host. Fertilization in the lower part of uteri. The egg is mammilated, oval, m-shape with three protective covering—outer protein layer, middle chitinous shell and inner membrane made of esterified glycosides.
- (15) Embryonic development takes place only outside the body of human host in soil because it requires low temperature, more oxygen and suitable moisture.
- (16) Inside the shell the zygote develops into rhabditiform larva or first stage juvenile in 10-14 days.
- (17) The larva of first stage is not infective. It rests for a week and completes first moult within egg and becomes second stage rhabditiform larva which is infective.
- (18) The transmission of infective stage through embryonated egg takes place by contaminated food and water.
- (19) The embryonated egg passes into the intestine of man and second stage larva hatches out from the egg.
- (20) Three types of migration by Ascaris larva are primary migration, secondary migration and aberrant migration.
- (21) Primary migration is from intestinal wall \rightarrow hepatic portal \rightarrow liver \rightarrow hepatic vein \rightarrow heart \rightarrow pulmonary artery \rightarrow lungs.

- (22) Secondary migration is from lungs back to intestine of the host ; lungs \rightarrow bronchi \rightarrow trachea \rightarrow pharynx \rightarrow gullet \rightarrow oesophagus \rightarrow stomach \rightarrow intestine.
- (23) In lungs, larva complete its second and third moulting (becomes third and fourth stage larva). In small intestine it completes fourth or final moulting and becomes fifth stage of larva.
- (24) Duration of wandering journey from intestine to intestine is about three weeks. Within 8-10 weeks adult Ascaris starts reproduction.

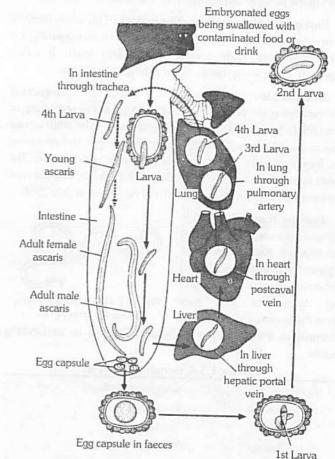

Fig: 1.7-21 Life cycle of Ascaris

- (25) Aberrant migration is the migration from lungs to brain, spinal cord, eyes, etc.
- (26) Ascaris is pathogenic. It cause the disease, ascariasis. Most pathogenic larva of Ascaris is fourth stage larva.
- (27) Main symptoms of ascariasis are abdominal discomfort, nausea, vomiting, diarrhoea and colic pain.
- (28) Toxin produced by Ascaris may interfere with protein digestion.
- (29) Ascariasis can be treated by antihelminthetic drugs such as oil of Chenopodium, Santonin, Antipar, Tetrachloroethylene, Alcopar, Decaris, Diethylcarbamazine, etc.

Some other nematode parasite:

Ancylostoma duodenale: It is an endoparasite of human small intestine. The parasite is monogenetic. It is popularly called old world hookworm. Adults live in the intestine of man and feed upon blood. No secondary host. Juveniles penetrate through the skin of hand and feet. It causes 'Ancylostomiasis'.

Wuchereria bancrofti: It is a digenetic parasite. Human being are primary host while female mosquito mostly of *culex* and Aedes species is the secondary or intermediate host.

Adults live in human lymph vessel and lymph glands. It is a viviparous nematode, larvae called 'microfilaria. Larvae appear in cutaneous blood (superficial blood) in midnight. Presence of few worms not harmful. They block lymph glands and lymph vessels, swell body parts like arms, scrotum and mammary glands. This results in the disease 'Elephantiasis' or 'Filariasis'

Enterobius Vermicularis (Pin worm): This worm inhabits human caecum, colon, appendix and rectum. It is monogenetic, no intermediate host. Eggs contain rhabditiform larva. It cause 'Oxyurasis', the main symptom being itching of anal parts.

Dracunculus medinensis: It is a digenetic endoparasite with man being the primary host and cyclops as the secondary or intermediate host. It is also called 'Fiery serpent'. The adult worms occur in the subcutaneous tissue, especially of arms, shoulders and legs, forming blisters. Female is very long while male is short. The guinea worm disease has been eradicated from India. The last case was reported from the Jodhpur district of Rajasthan in July 1996.

Loa loa (Eye worm): It is a filarial roundworm of central and Western Africa. The adult migrates through the subdermal connective tissues of human host. Sometimes they pass across the eyeball. Local swelling accompanies these migrations.

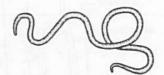

Fig: 1.7-22 Adult eye worm, Loa loa, from eye

accompanies these migrations. Tabanid flies act as transmitting vectors.

Table	:	1.7	7-5	Common	Names
-------	---	-----	-----	--------	-------

Ascaris	- Common roundworm
Ancylostoma	- Hookworm
Necator	- Hookworm
Wuchereria	- Filarial worm
Enterobius (Oxyuris)	- Pinworm
Trichuris	- Whipworm
Dracunculus	- Guinea worm
Loa loa	- Eye worm
Strongyloides	- Thread worm
	Ancylostoma Necator Wuchereria Enterobius (Oxyuris) Trichuris Dracunculus Loa loa

Phylum Annelida – The segmented Animals

(L.annelus = ring, eidos = form)

Brief History: Linnaeus (1758) included all soft-bodied worms in "Vermes". Lamarck (1801) established phylum annelida for higher types of worms.

General characters

- (1) Annelids are bilaterally symmetrical animals.
- (2) They have organ-system grade of organization.
- (3) They are coelomate (schizocoelomate) animals.
- (4) They have triploblastic body wall.

- (5) The muscle layers are thick in the body wall. Hence the body wall is said to be dermomuscular.
- (6) The body is divided into a numerous segments called the metameres or somites. The segmentation is known as metamerism.
 - (7) The body is covered with a thin cuticle.
 - (8) Locomotory organs are setae.
- (9) Digestive system is well developed. These have tubewithin-a-tube body plan.
 - (10) Blood vascular system is a closed type
- (11) Excretory system is formed of segmentally arranged nephridia.
 - (12) These always show cutaneous or skin respiration.
- (13) Nervous system is formed of a pair of cerebral ganglia (brain) and a double ventral nerve cord.
- (14) Mostly annelids are hermaphrodites. Fertilization is generally cross and may be external or internal.
- (15) The gonoducts are formed from coelom (coelomoducts). The coelomoducts have connection with nephridia.
 - (16) Regeneration is common character in this phylum.
- (17) Their development is direct or indirect and includes a free-swimming trochophore larva.

Classification of annelida: On the basis of position and arrangement of setae when present, absence and presence of sense organ, phylum annelida has been divided into four classes –

Class 1. Polychaeta (Gr. polus, many, chaite, hair)

- (1) Polychaeta are marine and carnivorous.
- (2) Body is elongated and segmented.
- (3) Head consists of prostomium and peristomium and bear eyes, tentacles, cirri and palps, etc.
- (4) Setae are numerous and are borne upon lateral prominances of the body wall known as parapodia.
 - (5) Locomotory organs are parapodia.
 - (6) Clitellum is absent.
 - (7) Cirri or branchiae or both may be present for respiration.
- (8) Coelom is spacious usually divided by inter segmented septa.
- (9) Alimentary canal is provided with an eversible buccal region and protrusible pharynx.
 - (10) Excretory organs are segmentally paired nephridia.
 - (11) Sexes are separate.
- (12) Fertilization is external; free swimming larval stage is trochophore.
 - (13) Asexual reproduction occurs by budding.

Examples : Nereis, Aphrodite, Polynae, Chaetopterus, Glycera, Arenicola, Amphitrite, Terebella, Sabella, Eunice, etc.

Arenicola, Amphitrite and Terebella have external gills.

☐ Chaetopterus exhibits luminescence and great power of regeneration.

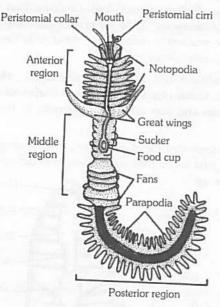

Fig: 1.7-23 Chaetopterus

Class 2. Oligochaeta (Gr. oligi, few)

- (1) They are mostly terrestrial or some fresh water forms.
- (2) Body has conspicuous external and internal segmentation.
- (3) Distinct head, eyes and tentacles are absent.
- (4) Parapodia are absent.
- (5) Locomotory organs are setae.
- (6) Setae are usually arranged segmentally.
- (7) Clitellum is usually present.
- (8) Pharynx is not eversible and without jaws.
- (9) They are hermaphrodites.
- (10) Development is direct and takes place within cocoons secreted by clitellum.
 - (11) No free larval stage

Examples: Tubifex, Dero, Pheretima, (Indian earthworms), Lumbricus (European earthworm).

☐ Tubifex and Dero are fresh water forms. Tubifex can live in polluted water where oxygen availability is poor because its has a large amount of haemoglobin in blood.

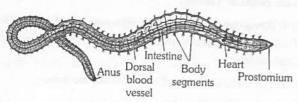

Fig: 1.7-24 Tubifex

Class 3. Hirudinea (L. hirudo, a leech)

(1) This class includes mostly ectoparasitic and fresh water forms, while few are marine, feeding upon fishes and other animals.

- (2) Body is elongated usually flattened dorso-ventrally or cylindrical.
- (3) Body consists or definite number of segments, each segments breaks up into 2 to 4 rings or annuli.
 - (4) Parapodia and setae are absent.
- (5) Body is provided with an anterior and a posterior sucker, both situated ventrally.
 - (6) Coelom is reduced by botryoidal tissue.
- (7) Mouth opens on the ventral surface in the anterior sucker, while anus opens dorsal to the posterior sucker.
 - (8) Locomotory organs are suckers.
 - (9) Hermaphrodite i.e., sexes united.
 - (10) Reproduction sexual. Asexual reproduction is unknown.
 - (11) Eggs are usually laid in cocoons.
 - (12) Development is direct without free swimming larval stage.

Examples : Acantobdella, Glossiphonia (Fresh water leeches), pontobdella, Haemodipsa, etc.

- ☐ Haemodipsa is terrestrial leech.
- ☐ Pontobdella is a ectoparasite on elasmobranchi fishes.
- ☐ Acanthobdella is a ectoparasite of salmon fish.

Class 4. Archiannelida (Gr. archi, primitive)

- (1) They are exclusively marine forms.
- (2) Body elongated and worm-like.
- (3) Setae and parapodia are usually absent.
- (4) External segmentation is slightly marked by faint while internal segmentation is marked by coelomic septa.
 - (5) Prostomium bears two or three tentacles.
 - (6) Unisexual or hermaphrodite.
 - (7) Larva is typical trochophore.

Examples: Polygordius, Protodrillus, Nerilla, Saccocirrus, etc.

☐ Polygordius is a primitive Archiannelid or living fossil.

Some representative animals

Pheretima posthuma

- (1) The common Indian earthworm, Pheretima posthuma belong to the class oligochaeta of the phylum Annelida. It is found in every part of the world. It lives in damp soil and burrow in lawns, fields, garden etc. rich in humus. Earthworm is nocturnal i.e., active during night.
- (2) The generic name Pheretima was first used by Kinberg in 1867. Our knowledge of Pheretima is mainly due to the work of Karm Narayan Bahl (1926).

(3) Body is cylindrical, bilaterally symmetrical, elongated with metameric segmentation. Earthworm shows both external and internal segmentation. The number of segments is about 100-120, the length is about 150 mm.

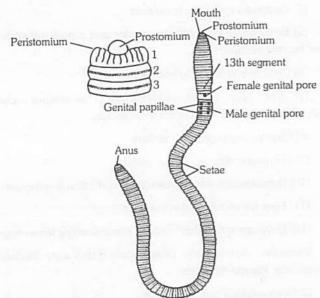

Fig: 1.7-25 Pheretima external features

- (4) Earthworm is brown or clay-coloured. This is because of the pigment porphyrin. Numerous granules of porphyrin pigment are found scattered in the circular muscle layer of body wall. Porphyrin protects the body from the injurious effects of bright light.
- (5) The first segment is peristomium or buccal segment which bears mouth. Anus is located on the last segment.
- (6) Three regions in body of earthworm are Preclitellar region (1 13), Clitellar region (14, 15, 16) and Postclitellar region (17 last).
- (7) Nephridiopores of integumentary nephridia 200-250 per segment are found in all segments except the first six. Clitellar segment contains 2000 nephridiopores per segment, so called 'forest of nephridia'.
- (8) In the body wall 11 pores are concerned with reproduction. They are Spermathecal pores in the intersegmental grooves of 5/6, 6/7, 7/8 and 8/9 (4 pairs). Female genital pore midventral on segment 14th. Male genital pores ventrolaterally (1 pair) on segment 18th.
- (9) Male genital papillae are present on segments 17 and 19 (2 pairs).
- (10) Body wall is dermomuscular, consisting of cuticle, epidermis, muscular layers and coelomic epithelium. Epidermis consists of tall, columnar cells of four types – Supporting cells (major part), Glandular cells (Goblet and albumin), Basal cells and Sensory cells.
- (11) All segments except the first, last and clitellar segment contain setae (perichaetine arrangement). Setae are 'S'-shaped, yellowish and chitinous, 80-120 segment. Setae and contraction of muscles help in locomotion.

- (12) The body cavity of earthworm is true coelom (schizocoel) as it is formed by the division of mesoderm. The coelom is filled with milky white alkaline coelomic fluid. Coelomic fluid contains different types of carpuscles. These are granulocytes (phagocytes), most numerous mucocytes, circular nucleated cells (leucocytes) and chloragogen cells (yellow cells).
- (13) Chloragogen cells are small, star-shaped, yellow cells concerned with storage of reserve food, deamination of proteins, formation of urea and also excretory (analogous to the liver of vertebrates).

(14) The alimentary canal of earthworm is a straight tube, representing a 'tube within tube plan, Location of different part of

alimentary canal are -Mouth Buccal chamber: $1-2\frac{1}{9}$ Buccal cavity Pharynx $: 2\frac{1}{2} - 4$ Pharynx Oesophagus : 5-7 Oesophagus Gizzard 10 Gizzard : 8 11 12 : 9-14 Stomach 13 Stomach : 15 onwards Intestine 15 Roof of pharynx contains Intestine pharyngeal glands containing 19 secreting chromophil cells 20 mucus and proteases. Gizzard 21 22 Intestinal is a thick muscular organ, caecum cavity lined by tough cuticle for 26 grinding. Wall of stomach 'calciferous glands' contains Cut part of which intestine secretion of 31 neutralizes the acidity of soil. Typhlosole (15) Due to presence of typhlosole the intestine divided into three region region, Fig: 1.7-26 Alimentary canal -Pretyphlosolar Pheretima post typhlosolar region, typhlosolar region. Intestinal caeca arise from segment 26 and extend forward upto segments 22 or 23.

- (16) Typhlosole is a highly glandular, vascular longitudinal ridge increasing the area for absorption of digested food.
- (17) Earthworms are omnivorous. Undigested particles as faeces are called as 'casting'.
- (18) Blood vascular system of earthworm is closed type. Blood is red in colour, respiratory pigment haemoglobin is dissolved in the blood plasma.
 - (19) The main longitudinal blood vessels are three -
 - (i) The dorsal blood vessel
 - (ii) The ventral blood vessel
 - (iii) The subneural blood vessel
 - (20) Important transverse vessels in first 13 segments are -

Lateral hearts (segments 7 and 9), Anterior loops (segments 10 and 11) and, Lateral oesophageal hearts (segments 12 and 13).

- (21) Dorsal blood vessel is distributive in segments 1 to 13. Flow of blood in dorsal vessel is from posterior to anterior direction.
- (22) Ventral vessel is found below alimentary canal, single, blood flows anterior to posterior direction.
- (23) Blood glands are three in number and present on 4th, 5th and 6th segments. These produce blood cells and haemoglobin.
- (24) Lymph glands are present on both sides of dorsal blood vessel from segment 26th and those behind it (one pair per segment, small and whitish). Lymph glands are supposed to produce certain phagocytic cells.

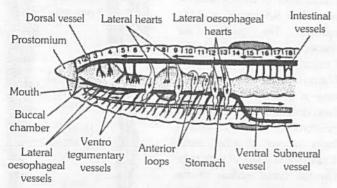

Fig: 1.7-27 Blood vascular system - Pheretima (After 13th segments)

- (25) Earthworm respires, but has no respiratory organs, exchange of gases takes place through moist skin. The absorptive area of earthworm is more than its volume, so earthworm does not require any respiratory organ. If the skin of the earthworm dries, it cannot respire. it dies due to asphyxia.
- (26) Excretory organs of earthworm are segmental nephridia ectodermal in origin, analogous to vertebrate kidney.
- (i) Pharyngeal nephridia are situated in the segments 4, 5 and 6. They open in anterior part alimentary canal. i.e. buccal cavity pharynx. They without nephrostome and are enteronephric type.
- (ii) Integumentary nephridia are scattered in the body wall. They are smallest, V-shaped without nephrostome and are exonephric type.

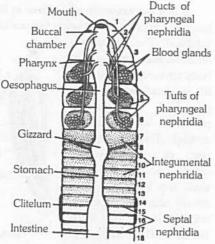

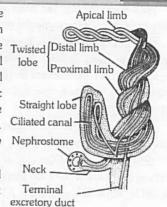

Fig: 1.7-28 Pharyngeal nephridia -Pheretima

(iii) Septal nephridia are the largest, attached to both facees of each intersegment septum behind 15th segment.

- (27) Septal nephridia are only nephridia with nephrostome or funnel. The terminal duct opens into septal excretory canal. Septal nephridia are enteronephric finally excretory products are poured into intestine. Earthworms mainly ureotelic.
- (28) Earthworm has a well developed nervous system; it has a brain but no head. Brain lies above pharynx, made up of Fig: 1.7-29 Septal nephridium pair of suprapharyngeal (cerebral) ganglia.

- Pheretima

- (29) Earthworm has no eyes, photoreceptors are used to judge intensity and duration of light, do not have the capacity of vision
- (30) Earthworm are hermaphrodite (monoecious) but fertilization is cross type due to protandrous condition.
- (31) In earthworm reproductive system consist of the following organs -

Male organs - Testes two pairs (segments 10 and 11) Seminal vesicles (segments 11 and 12) Accessory gland (segments 17 and 19) Genital papillae (segments 17 and 19) Male genital apertures (segments 18) Prostate gland (segments 17-20) Female organs - Ovary one pair (segment 13) Female genital pore (segment 14) Spermatheca 4 pairs (segments 6, 7, 8, 9)

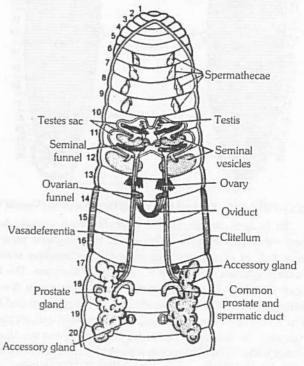

Fig: 1.7-30 Reproductive organs - Pheretima

- (32) Spermatheca are used to store sperms after copulation (open outside on intersegmental groove 5/6, 6/7, 7/8, 8/9).
- (33) Copulation occurs between two earthworms generally at night during rainy season. Fertilization is external and occurs in cocoon. Cocoons are formed by glandular clitellum. A cocoon may contain many fertilized eggs, but only one embryo develops, other eggs serve as nurse cells.
- (34) Cleavage is holoblastic and unequal, development is direct without any larval stage.
- (35) One of the oldest use of earthworm; it is used as bait for catching fish. Earthworms are friends of farmers because they enrich the soil by nephridial excretion, it increases the fertility of soil.

Hirudinaria granulosa

It is commonly known as Indian cattle leech. It is sanguivorous (feed on blood) segmented animal that live in ponds, streams, rice fields etc. It is ectoparasite on cattle and human. The body is soft, flattened and slimy. The dorsal side is yellowish green while the ventral side is orange. Botryoidal tissue is present in coelomic space.

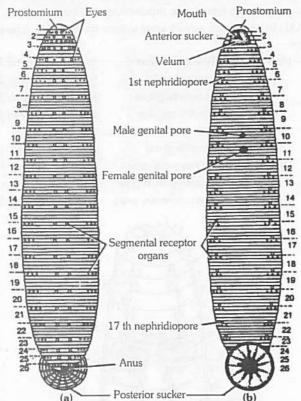

Fig: 1.7-31 Leech - External features (a) Dorsal View (b) Ventral View

The body is divisible into 33 segments. Each segment further appear subdivided superficially by annuli. Each segment from 6-22 bear a pair of ventral nephridiopore. During breeding season a temporary clitellum develps on 9, 10 and 11 segments. The leech bears two suckers. The anterior sucker encloses the mouth. It acts as a feeding locomotory and prehensile organ. The posterior end bears a large disc-shaped sucker that helps in locomotion and anchorage. It comprises the last seven uniannulate segments. Anus lies ahead of posterior sucker. Triradiate mouth is present at its bottom. The saliva of the leech contains an anti-coagulant, called hirudin which

prevents clotting of blood during blood meal. There are present five pairs of eyes on the dorsal surface. It is hermaphrodite but cross-fertilisation occurs. Development is direct. Prof. M.L. Bhatia has given a detailed morphology of *H. granulosa*.

Nereis

It is commonly called clam worm or sand worm or rag worm which is found on the sea shore in the tubular burrow. Nereis is unisexual and

its reproductive phase is called Heteronereis. Heteroneresis have two regions - epitoke or posterior sexual region and atoke anterior region without masses of developing gametes. The phenomenon of transformation of nereis into heteronereis is called epitocky. The gametes liberated through mixonephridia. Fertilization occurs in sea water. During development trochophore larva is present. The prominent head consists of prostomium and peristomium. The prostomium bears a pair of small tactile tentacles and a pair of stout palp. On the dorsal surface of the peristomium there are present two pair of black eyes. Peristomium has four pairs of long tentacles (cirri). Pharynx is everted for

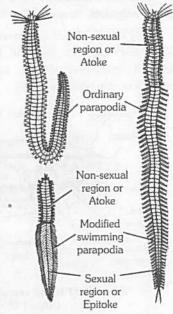

Fig: 1.7-32 Heteronereis

ingestion of food. Each segment bears laterally one pair of fleshy projection, the parapodia, used in swimming. The last segment has an anus. The anal segment is devoid of parapodia but bears a pair of elongated anal cirri.

Bonellia

It is a marine worm which lives in the crevices of the rocks. It has only traces of segmentation but sexual dimorphism is extremely

exhibited. The female has an ovoid and unsegmented Genital pore body covered with papillae. It is provided with a prostomial bifurcated proboscis homologous to annelids. There is only one large of ventral chitinous setae. The male is small and is reduced to a minute size of Turbellaria and lives in the body of the female. The larva of Bonellia the has potentialities of both male and female. If they develop

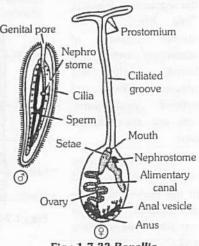

Fig: 1.7-33 Bonellia

independently they become females, but if they come in contact with female, they develop into males.

Aphrodite

The Aphrodite is a marine polychaete which is commonly called the 'sea mouse'. It is found burried in the mud or sand or crawling on the sea bed. The body is oval, broad and dorsoventrally flat and consists of 30-35 metameres. The body is covered with scales or elytra which are modifications of dorsal cirri of parapodia and are respiratory in function. The head is small and consists of a peristomium and a prostomium. The prostomium bears a pair of eyes, a short tentacle and a pair of long palps. During movement the animal changes colour from golden to peacock blue. The animal is commonly found in Atlantic and Mediterranean seas.

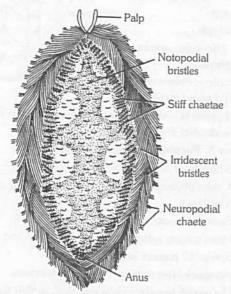

Fig: 1.7-34 Aphrodite

Table: 1.7-6 Common Names

Nereis	-	Ragworm
Aphrodite	-	Sea mouse
Polynoe	-	Scale worm
Chaetopterus	-	Paddle worm
Arenicola	-	Lugworm
Glycera	-	Smooth blood worm
Eunice	-	Palolo-worm
Sabella		Peacock-worm
Serpula	-	Fan-worm
Pheretima	-	Earthworm
Pontobdella	111-34	Skate-sucker
Hirudo	-	Medicinal leech
Hirudinaria	-	Cattle leech
Sipunculus	-	Pea-nut worm
Tubifex		Blood worm

Phylum Arthropoda – The animals with jointed feet

(Gk. Arthron = joint; Podos = foot)

Brief History: Aristotle described a few crabs and other arthropods. Linnaeus included all such animals in his group "Insecta". Lamarck divided this group into three classes – Crustacea, Hexapoda and Arachnida. Finally, Von seibold (1845) established the phylum Arthropoda for these animals.

General characters

- (1) Occur widely on land, in air, and in all sorts of water, from snowy tops of high mountains to the depths of ocean. Many are parasites of other animals and plants. Hence, the phylum is of great economic importance.
- (2) Bilateral, triploblastic, body segmented and also divided into head, thorax and abdomen. Segmentation marked only externally; number of segments or somites fixed and each has its separate exoskeleton of thick and hard, chitinous cuticle secreted by epidermis of body wall. Head somites always fused.
- (3) Each segment basically bears a pair of lateral jointed appendages adapted for food ingestion, locomotion, respiration, copulation, etc.
- (4) Muscular system well-developed; muscle fibres always striated.
- (5) Digestive tract is complete. Most head appendages forms mouth parts with lateral jaws for chewing or sucking. Anus is terminal.
- (6) Coelom is reduced to small cavities in excretory and reproductive organs; replaced elsewhere by blood sinuses which merge together to form a large perivisceral cavity the haemocoelaround viscera. Sinuses form an "open blood vascular system" filled with haemolymph which may contain haemocyanin. Haemocoel communicates with a long tubular and pulsatile, middorsal heart.
- (7) Respiration by gills (aquatic forms), or trachea or book lungs (terrestrial forms); by diffusion through body surface in some.
- (8) Excretion by coelomoducts or specialized green or coxal glands, or by malpighian tubules. Excretory product is uric acid.
- (9) Nervous system is basically similar to the typical annelid plan; head with a brain-ring which is connected to a double ventral nerve cord, having paired segmental ganglia which represent true metamerism. Well-developed sensory organs of various types.
- (10) Cilia completely absent. Muscles mostly striated and capable of rapid contraction.
- (11) Sexes mostly separate with sexual dimorphism. Paired reproductive organs and ducts.
- (12) Fertilization typically internal, in female's body. Eggs megalecithal. Oviparous or viviparous
- (13) Life-cycle includes one or more larval stages that metamorphose into adults.

Classification of Arthropoda: On the basis of body shape, degree of segmentation and regionation, and presence or absence of certain appendages (antennae, mandibles and chelicerae), phylum Arthropod is divided into four subphyla; Biggest phylum in regard to the number of species is Arthropoda.

Subphylum (I) Onychophora (Gr. Oychos = claw, phoros = bearing)

- (1) Terrestrial walking worms.
- (2) Body cylindrical with indistinct external segmentation.
- (3) Unjointed 14-43 pairs of legs.
- (4) Head not distinct, Oviparous/Viviparous
- (5) A pair of eyes, short antennae and blunt oral papillae.
- (6) Excretory organs are metanephridia which are segmentally arranged.
- (7) A living connecting link forming a transitional link between Annelida and Arthropoda.

Example: Peripatus, Ophisthopatus, Ooperipatus, etc.

Subphylum (II) Trilobitomorpha (Gr. TRIA = Three; LOBOS = lobe; MORPHE = form)

- (1) Most primitive, extinct, marine arthropods of Cambrian to Permian rocks.
- (2) 10 to 675 mm. Long body covered by a hard segmented shell; distinct head of four fused somites bearing a pair of antennae, four pairs of appendages and often a pair of eyes.
 - (3) Trunk divided, by two longitudinal furrows, into 3 lobes.
- (4) Abdominal region of 2 to 29 somites and a fused caudal plate or pygidium.
- (5) Each segment, except the last one, bears a pair of biramous jointed appendages.

Example - Triarthrus, Dalmenites.

Subphylum (III) Chelicerata (Gr. CHELA = Claw; CEROS = Horn; ATA = Group)

- (1) Mostly terrestrial, free-living and small-sized.
- (2) Body distinguished into head, thorax and abdomen (= opisthosoma). Head and thorax fused to form a cephalothorax or prosoma.
- (3) Cephalothorax with eyes and six pairs of appendages One pair of clawed and jointed chelicerae in place of mandibles, one pair of pedipalps, and four pairs of walking legs. Antennae absent. Abdomen with or without appendages, but distinguished into a large and broader mesosoma, a small metasoma and a long and narrow, tail–like telson.
 - (4) Respiration by gills book-lungs or tracheae.
 - (5) Excretion by malpighian tubules or coxal glands, or both.
- (6) Sexes mostly separate; females oviparous; development direct or through a larval stage. Divided into three classes on the basis of respiratory organs

 Median eye, Carapace of prosoma

Class 1. Merostoma

- (1) They are Marine.
- (2) Respiration by gills.
- (3) Cephalothorax with lateral compound eyes median simple eyes and six pairs of usual appendages.
- (4) Abdomen with 5 to 6 pairs of gill-bearing appendages.
- (5) Hind end forms a long bayonet-like telson.

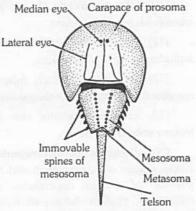

Fig: 1.7-35 Limulus

Example-Limulus (The king-crab).

☐ Limulus is a living fossil.

Class 2. Arachnida

- Mostly terrestrial;
 spiders, scorpions, mites,
 ticks, etc.
- (2) Respiration book–lungs or trachea.
 - (3) Eyes simple.
- (4) Abdomen without appendages.
- (5) Many with poison glands and poison fangs, jaws of stings.
 - (6) No gills.
- (7) Life-cyle without metamorphosis.

Examples- Palamnaeus (scorpion), Lycosa, mites, ticks.

(scorpion), Lycosa, mites, ticks.

Lycosa is a common web-spinning spider; web-spinning glands are situated in posterior part of abdomen.

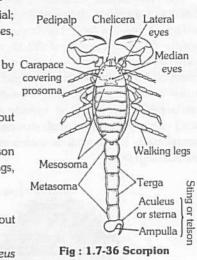

- (1) Small-sized marine sea-spiders.
- (2) Cephalothorax 3–segmented; forms major part of body; abdomen vestigeal.
 - (3) Suctorial mouth on top of a long proboscis.
 - (4) Head usually with 4 pairs of appendages and 4 eyes.
 - (5) 5, 6 or 12 pairs of long walking legs.
 - (6) No special respiratory and excretory organs.
 - (7) Unisexual; females oviparous. Eggs carried by males. Example Nymphon.

Subphylum (IV) Mandibulata or Antennata (L.MANDIBULA = Mandible; ATA = group)

- (1) Body divided into head and trunk, or head, thorax and abdomen.
 - (2) Segmentation distinct.
- (3) 1 or 2 pairs of antennae, 1 pair of mandible in place of chelicerae, one or more pairs of maxillae and 3 or more pairs of walking legs.
 - (4) Eyes mostly compound.
 - (5) Respiration by gills or trachea.
 - (6) Excretion by malpighian tubules or antennal glands.
- (7) Unisexual; life cycle usually with larval forms. Divided into six classes.

Class 1. Crustacea

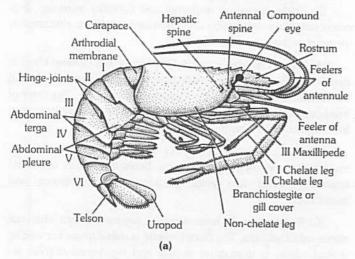

- (1) Mostly aquatic.
- (2) Body divided into cephalothroax and abdomen.
- (3) Dorsally, cephalothorax covered by a thick exoskeletal carapace.
- (4) Head of 5 segments, with 2 pairs of antennae, one pair of mandibles and 2 pairs of maxillae; thorax of 2 to 60 distinct or variously fused somites; abdominal somites usually distinct with a posterior telson.

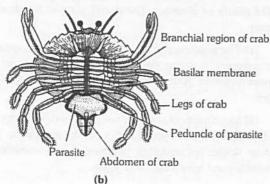

- (5) Appendages mostly biramous.
- (6) Respiration through body surface or by gills.
- (7) Excretion by special coxal glands in antennae or maxillae.
- (8) Mostly unisexual; genital ducts and pores paired; females oviparous.
 - (9) Life-cycle usually with larval forms.

Examples – Palaemon, Cancer, Cyclops, Astacus, Sacculina, Cypris, Daphnia, etc.

 $\ \square$ Tiny crustaceans such as Daphnia and cyclops act as zooplankton which form important link in the food chain in water.

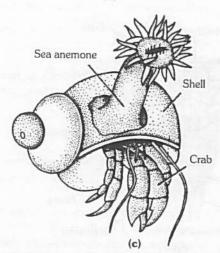

Fig: 1.7-37 (a) Prawn-External features (b) Sacculina (on host body) (c) Hermit crab (Commensalism)

Class 2. Insecta

- (1) Aquatic, terrestrial or aerial.
- (2) Body divided into head, thorax and abdomen.
- (3) Segments 6 in head, 3 in thorax and 11 or less in abdomen.
- (4) Legs typically 3 pairs (Hexapoda); aerial forms with one or two pairs of wings.
- (5) Head with 1 pair of large, compound eyes, 1 pair of antennae and variously modified mouth-parts.
- (6) Respiration by branched tracheae.

(9) Life-cycle simple or complicated.

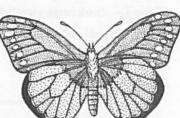

Fig: 1.7-38 Butterfly

Examples – *Periplaneta*, *Musca*, Mosquitoes, locusts, butterflies, bees, wasps, termites, silverfish, beetles, etc.

- Insects are of great economic importance to mankind.
- ☐ Silverfish is not a fish.

Class 3. Diplopoda

- (1) Terrestrial.
- (2) Body long, cylindrical, worm-like.
- (3) 5-segmented head with 1 pair each of short antennae, mandibles and maxillae; 2 groups of simple eyes.
- (4) Thorax of 4 segments, each except the first with a pair of joined legs.
- (5) Abdomen of 9 to 100 or more segments, but each apparent segment is formed by fusion of two and, hence, bears 2 pairs of legs, spiracles, ostia and nerve ganglia.
 - (6) Respiration by tracheae.
 - (7) Excretion by malpighian tubules.
 - (8) Unisexual; gonad single; females oviparous.

Example - Thyroglutus (millipede)

☐ Thyroglutus damages the root of crop plants.

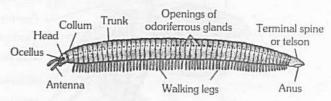

Fig: 1.7-39 Julus (millipede)

Class 4. Chilopods

- (1) Terrestrial.
- (2) Body long, worm-like, somewhat dorso-ventrally flattened and divided into head and trunk.

- (3) Segments 15 to 181; not fused in pairs; each with a single pair of legs; first pair of legs claw like and each contains a poison gland.
- (4) Head with a pair each of long antennae and mandibles, and 2 pairs of maxillae.
 - (5) Respiration by tracheae.
- (6) Unisexual; females oviparous or viviparous. Genital openings mid ventral on last but one segment.
 - (7) Excretion by malpighian tubules.

Example - Scolopendra (centipede).

☐ Diplopoda and chilopoda are together kept in myriapoda.

Class 5. Symphyla

- (1) Terrestrial.
- (2) Body upto 6 mm. Long; divided into head and trunk.
- (3) Head like that of insects, but without eyes.
- (4) Trunk of 15 to 22 somites; bears 10 to 12 pairs of legs.
- (5) Genital pores mid ventral between legs of 4th pair.

Example - Scutigerella (the garden centipede).

Class 6. Pauropoda

- (1) Terrestrial.
- (2) Minute, soft and cylindrical, worm like body divisible into head and trunk.
- (3) Head with one pair each of branched antennae and unbranched mandibles and maxillae; no eyes.
- (4) Trunk of 11 or 12 somites which are dorsally fused in pairs.
 - (5) Legs 9 to 10 pairs.
 - (6) Genital pores ventral on 3rd trunk segment.

Example - Pauropus.

Some representative animals

Cockroach (Periplaneta Americana)

- (1) Cockroach belong to the class insecta of the phylum Arthropoda.
- (2) Two species of cockroaches commonly found in India are— Periplaneta americana and Blatta orientalis. Periplaneta americana is the largest and most common species. The generic name periplaneta was given by Burmeister in 1838.
- (3) Cockroaches are nocturnal and cursorial (running). It is cosmopolitan in distribution, but cockroach are more abundant in warm, humid areas.
- (4) Body is divided into head, thorax and abdomen. Head is derived by the fusion of six embryonic segments. The part of head between and behind the eyes is epicranium (vertex). The front of head capsule is made up of three unpaired flattened sclerites called frons, clypeus and labrum.
- (5) The thorax consist of three segments-prothorax, mesothorax and metathorax. Thorax bears three pairs of jointed appendages and two pairs of wings on mesothorax and metathorax.
- (6) Exoskeleton of each segment consists of four chitinous plates called sclerites. The dorsal sclerite is called tergum or tergite, ventral sclerite is sternum or sternite and two lateral sclerites are called pleura or pleurites. The dorsal plate of the thorax is called notum
- (7) The antenna is made of many segments, podomeres. The first segment is scape (largest), second pedicel and rest many jointed flagellum. Antenna is a thigmoreceptor which is sensitive to touch.
- (8) Mouthparts of cockroaches are mandibulate type or cutting and chewing type. Mouthparts consists of labrum (upper lip), labium (lower lip), maxillae (segmented and resemble to a leg), mandibles and hypopharynx (tongue).

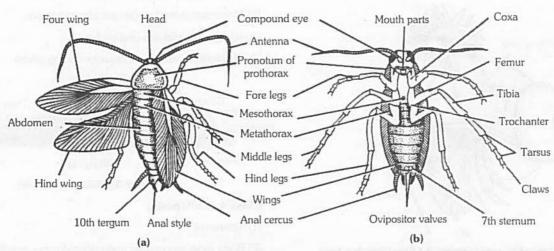

Fig: 1.7-40 Periplaneta - External features (a) Dorsal view (b) Ventral view

UNIVERSAL BOOK DEPOT 1950

- (9) The main structures of mastication (chewing) are mandibles which are short with teeth.
- (10) Maxilla consists of cardo, stipes, galea, lacinia and 5-segmented maxillary palp.
- (11) Labium (= second maxilla) consists of submentum, mentum, prementum, palpiger, paraglossa, glossa and three jointed labial palp.
- (12) Glossa and paraglossa are together called lingula. They push the masticated food into buccal cavity.
- (13) A common salivary duct opens at the base of the hypopharynx.

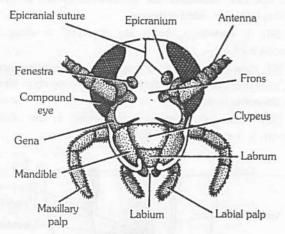

Fig: 1.7-41 Periplaneta - head

- (14) Each leg is formed by five segments, viz, coxa, trochanter, femur, tibia and tarsus (tarsus is made by five tarsomeres). Attached to the last tarsomere called pretarsus and it bears, a soft lobe called arolium or pulvilus and a pair of claws is present. They are helpful in moving on smooth surfaces. Plantulae are present on tarsus and act as thermoreceptors.
- (15) The most swollen segment in the leg of cockroach is coxa. The longest segment in the leg of cockroach is tibia.
- (16) In adult cockroach abdomen is made up of ten segments. But in embryonic stage eleven segments are present. The 11th segment of embryo is represented in adult by podical plates.
- (17) In male cockroach, eighth and ninth terga are overlapped by seventh tergum. In female seventh, eighth and ninth sterna are fused to form a brood pouch. Seventh sternum of brood pouch forms a pair of gynavalvular plates.
- (18) Anal cerci bear minute sensory hairs which are sensitive to sound and other vibrations.
- (19) Anal cerci, a pair of many jointed structures are present on the tergite of $10^{\rm th}$ segment in both sexes.
- (20) Anal styles, a pair of small, spine-like unjointed structures are present on sternite of 9^{th} segment in males only.
- (21) Cockroach has two pairs of wings. The first pair (mesothoracic) are thick, hard and leathery, protective in function called tegmina (= elytra). Second pair (metathoracic) are thin, soft and membranous.
- (22) Cockroach does not fly, but the wings help in escaping from danger.

- (23) Body wall of cockroach is made up of two layers, outer cuticle and inner hypodermis.
- (24) Cuticle is invaginated forming endoskeletal elements like tentorium in head and apodemes in thorax. They provide sites for attachment of muscles. The cuticle has three distinct layers, outer primary cuticle or epicuticle, middle thick exocuticle and inner thick endocuticle.
- (25) Hypodermis is a single layered epithelium. Some of its cells are modified into large oval trichogen cells concerned with secretion of movable bristles on the body of cockroach.
- (26) The body cavity of cockroach is a haemocoel, filled with blood.
- (27) The alimentary canal of cockroach is divisible into three parts, viz, foregut, midgut and hindgut.
- (28) Foregut (stomodaeum) is differentiated into five parts buccal chamber, pharynx, oesophagus, crop and gizzard. Gizzard is muscular and internally provided with six cuticular teeth which crush the food.
- (29) Midgut (mesenteron or ventriculus) is short, tubular, lined with glandular endoderm. At anterior end of mesenteron there are eight blind glandular hepatic caecae which secrete digestive enzymes. Internally mesenteron is not lined by cuticle but it is covered by a very thin and transparent peritrophic membrane formed of chitin and proteins.

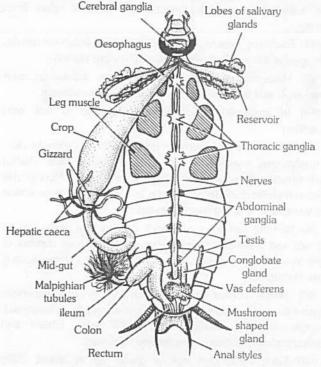

Fig: 1.7-42 Periplaneta - Alimentary canal

- (30) A stomodaeal valve is present between gizzard and mesenteron.
- (31) Hindgut (proctodaeum) comprises ileum, colon and rectum. The wall of rectum is provided with six rectal papillae, which help in the absorption of water and salts.
- (32) At the junction of foregut and midgut seven or eight finger like structure are present called hepatic caecae.

- (33) Cockroach is omnivorous, feeds on all sorts of organic debris. The digestive enzymes of saliva are mainly zymase and amylase. Most of the nutrients of food are digested in the crop Digested food is absorbed in the mesenteron and hepatic caecae.
- (34) Circulatory system in cockroach is of open type or lacunar type. In this type blood is always in direct contact with tissues. The blood flow through haemocoelic system.
- (35) The heart is situated in pericardial sinus over the dorsal diaphragm.
- (36) Heart of cockroach is neurogenic and longitudinally beaded with 13 chambers perforated by ostia having valves.
- (37) The blood circulation is maintained by 13 pairs of wingshaped involuntary alary muscles.
- (38) Blood (or haemolymph) is colourless due to the absence of respiratory pigment. Hence it does not take part in respiration. Blood is composed of plasma and colourless blood cells called haemocytes.
- (39) In cockroach oxygen is carried to individual cell without participation of blood. All body tissue receive oxygen directly.
- (40) Respiratory system of cockroach consists of tracheal system. The tracheal system opens outside by ten pairs of spiracles (two pairs thoracic and eight pairs of abdominal). The spiracles are with valves.
- (41) The first thoracic and first abdominal spiracles remain open all the times. The trachea is lined with spiral thickening of cuticle called intima which prevents the tracheal tubes from collapsing.
- (42) Excretory organs of cockroach are Malpighian tubules which open at the junction of midgut and hindgut (ileum).
- (43) Malpighian tubules absorb excretory substances from haemolymph and fat bodies and pass into the proctodaeum.
- (44) In cockroach chief excretory product is uric acid (uricotelism).
- (45) Fat body of cockroach contains mainly four types of cells. viz., trophocytes, mycetocytes, oenocytes and urate cells. The fat body is functionally analogous to liver of vertebrates. Mycetocytes contain symbiotic bacteria which help in synthesis of some amino acids, vitamins and of glycogen from glucose.
- (46) Nervous system of cockroach consists of a nerve ring (in the head) and a double ventral nerve cord. The total number of ganglia in ventral nerve cord of cockroach is nine (Three thoracic and six abdominal).
- (47) Sense organs in cockroach are Photoreceptors (compound and simple eyes), thigmoreceptors (antennae), chemoreceptors (on maxillary and labial palps, labium and hypopharynx) and auditory receptors on anal cerci.
- (48) Each compound eye is made up of about 2000 functional units called ommatidia.
- (49) Each ommatidium is composed of a cuticular lens, two corneagen cells, a crystalline cone surrounded by four cone cells, a rhabdome surrounded by seven retinular cells and a basement membrane.
- (50) There are two types of vision in insects, mosaic vision or apposition image during day time and superposition or dull image in dim light.

- (51) The vision in cockroach is called mosaic vision because in cockroach, pigment sheath of ommatidia is non-contractile so capable of only mosaic vision even during night.
- (52) Simple eye of cockroach is mainly concerned with light collecting rather than image forming.
- (53) In cockroach the endocrine organs are cardiac, corpora allata and prothoracic glands.
- (54) Corpora cardica and corpora allata are attached to the brain. Corpora allata is neurosecretory and secretes juvenile hormone or neotinin.
- (55) Intercerebral glands in brain secrete the brain hormone. Brain hormone stimulates the prothoracic glands to secrete a moulting hormone called ecdysone.
- (56) In cockroach, sexes are separate, so dioecious or unisexual animal.
- (57) Male organs consist of testes, vasa deferentia, ejaculatory duct, mushroom or utricular gland, phallic or conglobate gland and male gonaphophysis.
- (58) Testes of cockroach are located in the abdominal segments 4, 5 and 6. They produce sperms.

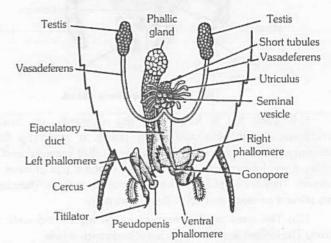

Fig: 1.7-43 Periplaneta - Male reproductive organs

- (59) All sperms of a seminal vesicle are glued together into a large bundle called spermatophore. Spermatophore has three-layered wall. Inner layer secreted by utriculi majores; middle layer secreted by ejaculaiory duct and outer layer secreted by phallic gland.
- (60) There are three asymmetrical chitinous structures called male gonapophyses or phallomeres. Right phallomere has serrated edges and a hook; left phallomere has an asperate lobe, pseudopenis and a hooked titillator and ventral phallomere is simple.
- (61) Female organs consist of ovaries, oviducts, vagina, genital chamber, spermathecae, colleterial glands and female gonapophysis (ovipositor processes). Ovaries of cockroach are located in the abdominal segments 2 to 6. Each ovary is made up of eight ovarioles.
- (62) Oviducts fuse to form a common oviduct or vagina. It opens into gynatrium. Gynatrium opens out through female gonopore.

- (63) Collaterial glands opens into gynatrium through a common pore. Left collaterial gland secrete HCI and scleroprotein and right gland secrete hydroxy phenol. Ootheca of cockroach is formed of a protein secreted by collaterial glands.
- (64) A pair of spermathecae (left larger pyriform sac) are present near female genital pore. They store spermatophores received during copulation.

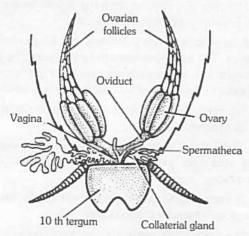

Fig: 1.7-44 Cockroach -Female reproductive organs

- (65) Near the female gonopore three pairs of gonapophyses are present. They are helpful in copulation and in oviposition.
- (66) Ootheca of cockroach contains 16 fertilized eggs in two rows (8 \pm 8). The egg of cockroach is centrolecithal type.
 - (67) Nymph of cockroach emerges out from ootheca.
- (68) Metamorphosis in cockroach is incomplete or paurometabolous type. Metamorphosis is regulated by two hormones, ecdysone secreted by prothoracic glands and juvenile hormone secreted by corpora allata.

Mosquito (Anopheles)

- (1) Mosquito are inhabitants of damp and marshy places.
- (2) The common genera of mosquito are -

Culex (body held parallel to surface while sitting),

Aedes (= Stegomyia) (body held parallel to surface while sitting, with black and white striped body),

Anopheles (Body held at an angle to the surface, dark spotted wing).

(3) The body of mosquito is divided into head, thorax and abdomen. Head bears a pair of antennae, compound eyes and mouth parts.

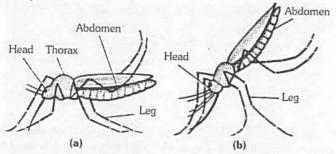

Fig: 1.7-45 Mosquitoes (a) Culex (b) Anopheles

- (4) In adult mosquito, ocelli (simple eyes) are totally absent (in cockroach and housefly, ocelli are present).
- (5) Thorax is three-segmented with only one pair of wings (mesothoracic). Metathoracic wings are modified into halteres which are balancing and sound producing structures.
- (6) Mosquito shows sexual dimorphism. Sex differentiation can be done on the basis of antennae and maxillary palps. Antenna of a male mosquito is plumose (more hairy or brushy) and female is pilose (with few short hairs).
- (7) Female mosquitoes are blood suckers. They have piercing and sucking mouthparts. Males feed on nectar and have only sucking mouthparts.
- (8) Mouthparts found in both sexes are Labrum, epipharynx forming upper lip and labium and proboscis.
- (9) The puncturing elements in the mouthparts of female mosquito are maxillae and mandibles.

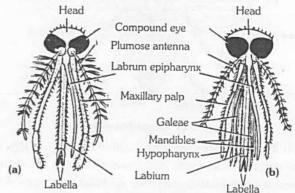

Fig: 1.7-46 Anopheles head and mouth parts
(a) Male (b) Female

- (10) Mandible are totally absent in male mosquito.
- (11) Male and female mosquito copulate while in flight. The eggs are laid by the female in clusters on stagnant water of ponds, ditches, tanks, pools marshy places etc. The eggs develops and from each egg a small transparent larva called wriggler comes out into the water.
- (12) Wriggler is a free swimming, active and aquatic larva performing wriggling movements. The body has head, thorax (without legs) and abdomen (9-segmented). Head bears a pair of compound eyes, a pair of simple eyes (absent in adult mosquito), a pair of small antennae.
- (13) Wriggler has a lifespan of 3-4 days. During this period it undergoes four moults to give rise to five instar larva.
- (14) 5th instar larva changes into a pupa (nonfeeding), it is comma-shaped. The pupa of mosquito is known as tumbler. It has a pair of respiratory trumpets.
- (15) After completion of metamorphosis (complete metamorphosis), it will transform into an adult called 'Imago'.
- (16) Johnston's organ lies in the second segment of antennae. In male mosquito, it helps to locate females by flight tone.
- (17) Spraying of oil on stagnant water controls malaria because mosquito larvae cannot breath and die.
- (18) Fish which can be used in biological control of mosquitoes is Gambusia.

Housefly (Musca domestica)

- (1) Housefly belong to the class insecta of the phylum Arthropoda. *Musca domestica* is the most common housefly in Europe and America. The common Indian species in *musca nebulo*.
- (2) The body of housefly is divided into head, thorax and adbomen.
- (3) Head is large with a pair of compound eyes, each made up about 4000 ommatidia, three ocelli and two antennae.

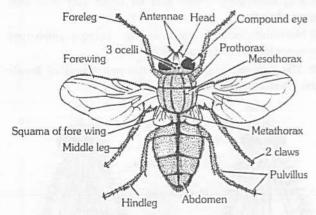

Fig: 1.7-47 Musca domestica

(4) Thorax is three segmented with three pairs of legs, one pair of wings (mesothoracic) and a pair of halteres. The halteres are present on metathorax and they are balancing organs during flight and also receive sound stimuli.

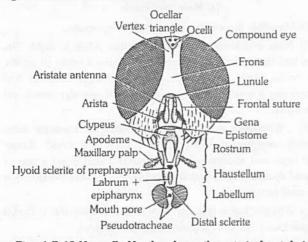

Fig: 1.7-48 Housefly-Head and mouth parts in frontal view

- (5) Housefly differs from mosquito in having hindlegs resting on surface while sitting.
- (6) The mouth parts of the common housefly are sponging type which are adapted for sucking liquid or semiliquid.
- (7) Labium is the most developed part of mouthparts forming the proboscis. The proboscis consists of three region Rostrum, Haustellum, Labellum.
- (8) Oral groove is found on haustellum cantaining blade-like hypopharynx and flattened labrum and epipharynx.
 - (9) Pseudotracheae are found in labellum.

- (10) In the mouth parts of housefly, mandibles are totally absent.
- (11) House flies are saprophagus, feed upon all sorts of dead organic matter.
- (12) The breeding season of housefly lasts from march to october (summer and rainy season).
- (13) Housefly lays eggs on decaying organic matter such as cow dung, horse manure, human faeces etc.
- (14) A larval stage occurs in housefly that lives in dung and is called maggot. This larva undergoes moulting twice. The period in between two moults is known as stadium while the form of larva are called instar. Thus there are two moult and three instars.
- (15) The first instar has only one pair of posterior abdominal spiracles. So it is metapneustic.
- (16) The second instar larva of housefly has one pair of abdominal and one pair of prothoracic spiracles. So it is amphipneustic.
- (17) Different stages in the life history of housefly are Egg \rightarrow Larva (maggot) \rightarrow pupa \rightarrow Imago (adult).
 - (18) Larva of housefly respires by means of tracheae.
- (19) An imago (young one of housefly) will come out after 4-5 days.
- (20) Housefly shows a complete metamorphosis (holometabolous type).

Table: 1.7-7 Common Names

Table :	1.7-7 0	ommon Names	
Limulus		King carb	
Palamnaeus	-	Scorpion	
Lycosa		Spider	
Astacus	-	Crayfish	
Daphnia	-	Waterflea	
Palaemon	-	Freshwater prawn	
Palinurus	-16	Lobster	
Lucifer	-	Shrimp	
Carcinus	-	Crab	
Eupagurus	=	Hermit crab	
Balanus		Rock barnacle	
Julus		Millipede	
Scolopendra	-	Centipede	
Lepisma	-	Silverfish	
Carasius	-	Stick insect	
Phyllium	-	Leaf insect	
Pediculus	-	Louse	
Cimex	-	Bedbug	
Xenopsylla	_	Rat flea	
Drosophila	-	Fruitfly	
Musca	NE I	Housefly	
Phlebotomus	-	Sandfly	
Glossina	-	Testse fly	
Bombyx	-	Silkmoth	

shell plates

Phylum Mollusca - The soft bodied animals

(L., Mollis or Molluscus = Soft bodied)

Brief History: Aristotle described a number of molluscs. Johnston (1650) proposed the name of the phylum.

General characters

- (1) Molluscs are multicellular organisms.
- (2) They are mostly marine.
- (3) They have a bilateral symmetry, but snails are asymmetrical.
 - (4) They are triploblastic animals.
- (5) They are coelomate animals. True coelom is reduced and haemocoel is well developed in them.
 - (6) They have organ system grade of organization.
 - (7) The body is soft and unsegmented.
- (8) The soft body is covered by a fleshy fold of the body wall. It is called mantle.
- (9) The molluscs are provided with one or two calcareous shells. The shells may be external or internal, univalve or bivalve.
- (10) Respiration is carried out by the gills or pulmonary chambers.
- (11) The digestive system is well developed. It contains a radula and a hepatopancreas.
- (12) The circulatory system is of an open type. Blood with amoebocytes, respiratory pigment is copper containing haemocyanin dissolved in plasma.
 - (13) The excretory organ is the kidney (organ of Bojanus).
- (14) The nervous system is well developed with paired ganglia, commissures and connectives.
- (15) The sensory organs are eyes, statocysts and osphradia (a chemoreceptor to test chemical nature of water).
- (16) Reproduction is sexual. Sexes are separate in them, or they are hermaphrodites.
- (17) The development in their case is either direct or indirect with free larval forms like trochophore, veliger, glochidium, etc.

Classification of Mollusca: On the basis of body shape and symmetry and characteristics of foot mantle, respiratory organs, nervous system, etc. phylum mollusca are divided into seven classes:

Class 1. Monoplacophora

- (1) The body is bilaterally symmetrical and segmented.
- (2) The shell is formed of a single valve.
- (3) The head is without eyes and tentacles.
- (4) The gills are external and serially arranged.
- (5) The nephridia are five pairs.

Example: Neopilina galathea

 $\ \square$ Neopilina is a living fossil and connecting link between Annelida and Mollusca.

Class 2. Aplacophora or Solenogasters

- (1) The body is worm-like, bilaterally symmetrical and cylindrical.
 - (2) The head, mantle, foot, shell and nephridia are absent.
 - (3) The body is covered with spicule-bearing cuticle.
 - (4) The digestive tract is straight with radula.
 - (5) A mid dorsal longitudinal keel or crest is often present .

Example: Neomenia, Chaetoderma, etc.,

Class 3. Polyplacophora

- (1) These molluscs are bilaterally symmetrical, and dorsoventrally flattened.

 Calcareous
- (2) Head small, without eyes and tentacles.
- (3) The shell is composed of a longitudinal series of 8 plates.
 - (4) The foot is flat and ventral.
 - (5) The radula is well developed.
- (6) Respiration by 8 to 60 pairs of gills.

Mantle

Calcareous

Fig: 1.7-49 Chiton

(7) Unisexual; only one gonad; trochophore larval stage.

Example: Chiton, Cryptochiton, etc.

On the dorsal surface of chiton is a convex shell composed of 8 transversely elongated calcareous plates arranged in a longitudinal manner.

Class 4. Gastropoda

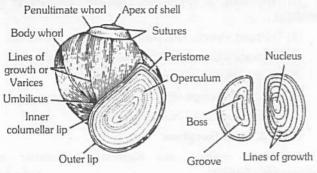

- It is the largest class of Mollusca.
- (2) It seems that these animals are moving on their stomach, hence the name gastropoda.
- (3) Gastropods are marine, fresh water or terrestrial animals. A few are parasitic.
 - (4) The body is unsegmented and asymmetrical.
 - (5) The shell is univalve and spirally coiled due to torsion.
 - (6) The head is distinct. It bears tentacles, eyes and a mouth.
 - (7) The foot is ventral and muscular.
 - (8) The buccal cavity is provided with a radula.
 - (9) The circulatory system is open.
- (10) Respiratory organs are gills (ctinidia), or pulmonary sac or both.
 - (11) Nervous system usually with four pairs of ganglia.
- (12) The sexes are mostly separate, while some forms are hermaphrodite.
- (13) The development includes veliger and trochophore larvae.

Examples : Haliotis, Cypraea, Pila, Murex, Aplysea, Doris, Limax, Patella, etc.

 \square Limax is a terrestrial gastropod. It creeps on a self-secreted tract.

☐ Doris is a marine gastropod, commonly called true limpet. It has an aspidobranch gill.

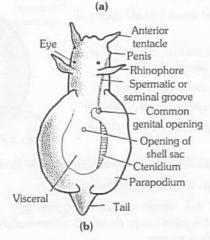

Fig: 1.7-50 (a) Pila globosa (b) Aplysia

Class 5. Scaphopoda

- It is the small group of marine molluscs.
 - (2) The foot is boat-shaped.
- (3) The eyes, the tentacles and ctenidia are absent.
- (4) Marine, bilaterally symmetrical molluscs.

Examples : Siphonodentalium Dentalium, and Pulsellum

 Dentalium is commonly called tusk shells.

- Pelecypoda or Fig : 1.7-51 Dentalium ibranchiata
- (1) Pelecypoda are aquatic in habit.
- (2) The body is bilaterally symmetrical and laterally compressed.
 - (3) The shell is formed of two distinctive shell plates.
 - (4) The head is not distinct.
 - (5) The alimentary canal shows a crystalline style.
- (6) The gills, excretory organs and the other structures are paired.

- (7) The sexes are separate or united.
- (8) The development is indirect having a glochidium larva.

Example : Mytilus, Unio, Teredo, Lamellidens, Solen, Pecten, Punctada, etc.

- $\ \square$ Teredo bores through wood of ship but is without segmentation.
 - Pearl oysters belongs to the class pelecypoda.

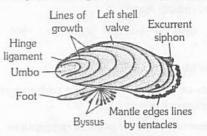

Fig: 1.7-52 Mytilus

Class 7. Cephalopoda or Siphonopoda

- (1) Most developed, marine and actively swimming by ejecting jets of water through exhalent siphon of mantle.
 - (2) The body is bilaterally symmetrical.
 - (3) The foot is modified into arms and funnel.
- (4) The shell may be either absent or rudimentary; it may be internal or external.
 - (5) Nervous system is highly developed.
 - (6) The odonotophore with a radula is present.
 - (7) The ink-gland is present.
 - (8) The sexes are separate.

Dorsal

shell

Shell

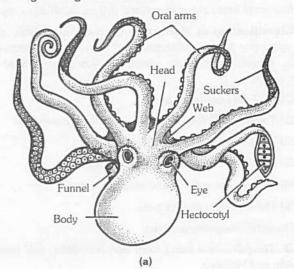

Captacula

Foot

(9) The development is direct hence no metamorphosis and larval stage.

Example: Nautilus, Loligo Sepia, Octopus, etc.

- ☐ Nautilus has an external coiled and chambered shell.
- Octopus has good learning power and can be trained.
- Members of genus Architeuth are known as giant squid and are largest living invertebrates.

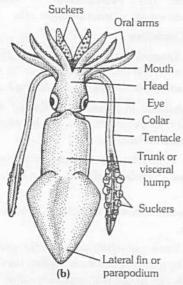

Fig: 1.7-53 (a) Octopus (b) Sepia

Table	: 1.7-8	Common Names	
Chiton	-	Sea mica (Mail shell)	
Dentalium	-	Tusk shell	
Patella	The state of	Limpet	
Fissurella	-	Key-hole limpet	
Trochus	400 E	Top shell	
Pila	-	Apple snail	
Crepidula	-	Slipper shell	
Cypraea	-	Cowrie	
Natica	-	Star shell	
Buccinum	-	Whelk	
Doris	-	Sea lemon	
Aplysia	-	Sea hare	
Turbo	-	Cat's eyes	
Vermetes	_	Worm shell	
Nassa	_	Mud shell	
Conus	-	Cone shell	
Bulla	-	Bubble shell	
Helix	-	Land snail	
Limax	-	Slug	
Pteropod	_	Sea butterfly	
Unio	***	Freshwater mussel	
Mytilus	-	Sea mussel	
Spondylus	-	Edible oyster	
Pinctada	-	Pearl oyster	
Pecten	-	Scallop	
Teredo	-	Shipworm	
Solen	-	Razor clam	
Sepia	-	Cuttlefish	
Loligo	-	Squid (sea arrow)	
Octopus	-	Devilfish	
Spirula	-	Spiral shell	
Architeuthis	-	Giant squid	

Phylum Echinodermata – The spiny skinned animals

(Gk. echinos = spines; derma = skin/covering)

Brief History: Although Jacob Klein (1738) had earlier coined the name "Echinodermata", yet Linnaeus included these animals under "Mollusca", and Lamarck under his class "Radiata" as "Echinodermes". Finally, Leuckart (1847) raised the group to the status of a separate phylum.

General characters

- (1) Echinoderms are exclusively marine beings.
- (2) They are triplobalstic and coelomate (enterocoetomate) animals.
- (3) They have radially symmetrical body. The radial symmetry is due to sedentary or sessile mode of life and it is a secondary character in echinoderms.
 - (4) They have organ system grade of organization.
- (5) They have well developed endoskeleton formed of calcareous ossicles and spines.
- (6) They have a water-vascular system (Ambulacral system) with tube-feet for locomotion, feeding and respiration.
 - (7) Circulatory system is of the open-type.
- (8) Respiratory organs include dermal branchiae, tube feet, respiratory tree and bursae.
- (9) Nervous system is complex and contains both central and peripheral components, but no brain.
 - (10) The sensory organs are poorly developed.
 - (11) The excretory organs are absent.
 - (12) They have pedicellariae.
 - (13) Development is indirect.
 - (14) The larval forms are bilaterally symmetrical.
 - (15) Regeneration power is well developed in Echinoderms.

Classification of Echinodermata: On the basis of body shape, position of madreporite and kind of larval form, echinoderms are classified into two subphylum.

Subphylum (I) Eleutherozoa : Free-living echinoderms with ventral mouth.

Class 1. Asteroidea

- Starfishes or sea stars.
- (2) Arms 5 or more and not sharply marked off from the central disc.
 - (3) Tube feet in orally placed ambulacral grooves; with suckers.

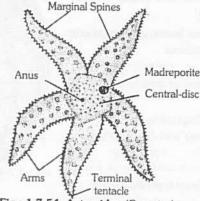

Fig: 1.7-54 Asteroidea (Sea star)

- (4) Anus and madreporite aboral.
- (5) Pedicellariae present.
- (6) Free-living, slow-creeping, predaceous and scavengerous.

Examples: Astropecten, Luidia, Goniaster, Oreaster (= Pentaceros), Asterina, Solaster, Pteraster, Echinaster, Asterias, Heliaster, etc.

Class 2. Ophiuroidea

- (1) Brittle-stars and allies.
- (2) Body star-like with arms sharply marked off from the central disc.
 - (3) Pedicellariae absent.
 - (4) Stomach sac-like; no anus.
- (5) Ambulacral grooves absent or covered by ossicles; tube feet without suckers.
 - (6) Madreporite oral.

Examples: Ophiura, Ophiothrix, Ophioderma, Ophiopholis, Gorgonocephalus, Asteronyx.

Class 3. Echinoidea

- (1) Body not divided into arms; globular (sea urchins), or flattened disc-like (sea-cakes).
- (2) Mouth at lower pole, covered by 5 strong and sharp teeth, forming a biting and chewing apparatus called "Aristotle's Lantern".
 - (3) Tube-feet slender with suckers.
- (4) Skin ossicles fused to form a rigid globular, disc like, or heart-shaped shell or test with movable spines.
 - (5) 3-jawed pedicellariae present in skin.
 - (6) Gut long, cylindrical and coiled. Anus present.
 - (7) Larval forms pluteus and Echinopluteus.

Examples : Echinus, Clypeaster, Echinarachinus, Echinocardium, etc.

Members of Echinoidea are also known as Floating stone.

Class 4. Holothuroidea

- Body massive, long and cylindrical like a cucumber; elongated in oral-aboral axis; no arms.
- (2) Mouth at anterior and anus at posterior ends.
- (3) Mouth surrounded by many hollow retractile tentacles.
- (4) Tube feet usually present; sucker-like.
- (5) Skin leathery, but relatively soft, without spines or pedicellariae; may have an endoskeleton of minute calcareous ossicles.
- (6) Respiration and excretion by two long and highly branched tubes (= respiratory tree) extending into coelom from cloaca.
 - (7) Larval form Auricularia.

Examples - Holothuria, Cucumaria etc.

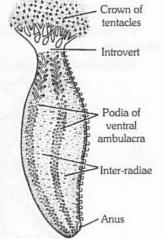

Fig: 1.7-55 Holothuria

Subphylum (II) Pelmatozoa : Stalked, sedentary echinoderms, with mouth situated on upper side.

Class 1. Crinoidea

- (1) Body flattened and pentamerous; distinguished into a small and circular central disc and five or more (in multiples of five) long, then, branched and flexible arms radiating from the disc.
- (2) Disc enclosed in a hard, cup-shaped calyx formed of calcareous plates; calyx attached to a substratum by a stalk or simply by its aboral surface.
- (3) Mouth in middle and anus excentral upon a cone, both upon oral surface. 5 ambulacral grooves run from mouth upto the tips of the arms.
- (4) Tube feet sucker-like; restricted to central disc; can help in food-collection.
- (5) Some forms (sea-lilies) permanently sessile and attached to sea-bottom by a long stalk; others (feather stars) free-swimming, but have flexible cirri for gripping objects in water.
 - (6) Spines and pedicellariae absent in skin.

Examples: Antedon, Neometra, etc.

Table: 1.7-9 Common Names

Asterias	-	Starfish
Astropecten	-	Starfish
Pentaceros	_	Sea pentagon
Ophiothrix	-	Brittle star
Gorgonocephalus	-	Basket star
Echinus	-	Sea urchin
Echinocardium	_	Heart urchin
Clypeaster	=	Sand dollar
Cucumaria	-	Sea cucumber
Antedon	-	Feather star

Phylum Chordata

General Characters

- Aquatic, aerial or terrestrial. All free-living with no fully parasitic forms.
- (2) Body small to large, bilaterally symmetrical and metamerically segmented.
- (3) A post anal tail usually projects beyond the anus at some stage and may or may not persist in the adult.
- (4) Exoskeleton often present; well developed in most vertebrates.
- (5) Body wall triploblastic with 3 germinal layers : ectoderm, mesoderm and endoderm.
- (6) Coelomate animals having a true coelom, enterocoelic or schizocoelic in origin.
- (7) A skeletal rod, the notochord, present at some stage in life cycle.
- (8) A cartilaginous or bony, living and jointed endoskeleton present in the majority of members (vertebrates).

UNIVERSAL BOOK DEPOT 1950

- (9) Pharyngeal gill slits present at some stage; may or may not be functional.
 - (10) Digestive system complete with digestive glands.
- (11) Blood vascular system closed. Heart ventral with dorsal and ventral blood vessels. Hepatic portal system well developed.
- (12) Excretory system comprising proto-or meso- or metanephric kidneys.
- (13) Nerve cord dorsal and tubular. Anterior end usually enlarged to form brain.
 - (14) Sexes separate with rare exceptions.

Classification of chordata: Phylum chordata can be divided into two groups: Acrania (Protochordata) and Craniata (Euchordata) having contrasting characters.

Group A. Acrania (Protochordata): (Gk. a = absent; kranion = head,) or, (Gk. protos = first; chorde = cord). All marine, small, Primitive or lower chordates. Lacking a head, a skull or cranium, a vertebral column, jaws and brain. About 2,000 species. The Acrania is divided into three subphyla: Hemichordata, Urochordata and Cephalochordata, chiefly on the character of notochord present.

Subphylum I. Hemichordata: (Gk. hemi = half; chorde = cord). Body divided into 3 regions: Proboscis, collar and trunk. Notochord doubtful, short, confined to proboscis and non-homologous with that of chordates.

Class 1. Enteropneusta: (Gk. enteron = gut; pneustos = breathed). Body large and worm-like. Gill slits numerous. Intestine straight. Acorn or tongue worms. 70 species. e.g. Balanoglossus, Saccoglossus.

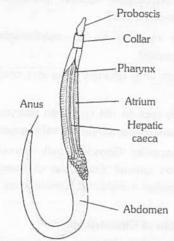

Fig: 1.7-56 Balanoglossus

Class 2. Pterobranchia: (Gk. pteron = feather; branchion = gill). Body small and compact. Gill-slits one pair or none. Intestine U-shaped. Pterobranchs. 20 species. e.g. Cephalodiscus, Rhabdopleura.

Subphylum II. Urochordata or Tunicata : (Gk. *oura* = a tail;) (L. *chorda* = cord). Notochord and nerve cord only in tadpole-like larva. Adult sac-like, often sessile and encased in a protective tunic. Tunicates.

Class 1. Ascidiacea: Sessile tunicates with scattered muscles in tunic. Solitary, colonial or compound. Gill-clefts numerous. Ascidians or sea squirts. 1,200 species. e.g. Herdmania, Ciona, Molgula.

Retrogressive metamorphosis present in Herdmania.

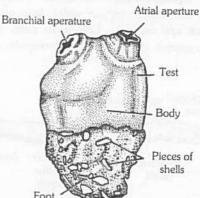

Fig: 1.7-57 Herdmania (Sea-squirt)

Class 2. Thaliacea: Free-swimming or pelagic tunicates with circular muscles in tunic. Sometimes colonial. Salps or chain tunicates. 30 species. Salpa, Doliolum, Pyrosoma.

Subphylum III. Cephalochordata: (Gk. kephale = head;) or (L. chorda = cord). Notochord and nerve cord present throughout life along entire length of body.

Class Leptocardii: Body fish-like, segmented with distinct myotomes and numerous gill-slits. Free swimming and burrowing. Lancelets. 30 species. e.g. Branchiostoma (= Amphioxus), Asymmetron.

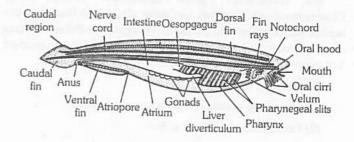

Fig: 1.7-58 Amphioxus

Group B. Craniata (Euchordata): Aquatic or terrestrial, usually large-sized, higher chordates or vertebrates with distinct head. Notochord is embryonic, in adult replaced by vertebral column. Jaws and brain protected by a skull or cranium. The Craniata includes a single subphylum, the vertebrata.

Subphylum IV. Vertebrata: (L. vertebratus = backbone). Notochord supplemented or replaced by a vertebral column or backbone composed of overlapping vertebrae. Body divisible into head, neck, trunk and tail. Usually dioecious. Vertebrates, largest chordate subphylum including about 46,500 species. The subphylum Vertebrata is divided into two divisions: Agnatha and Gnathostomata, with contrasting characters as follows;

Division I. Agnatha: (Gk. a, not; gnathos, jaw). Jaw less primitive fish-like vertebrates without true jaws and paired limbs.

Class 1. Ostracodermi. (Gk. ostrakon = shell; derma = skin). Several extinct orders of ancient primitive heavily armoured, Palaeozoic, world's first vertebrates, collectively called the ostracoderms. e.g. Caphalaspis, Drepanaspis.

Class 2. Cyclostomata. (Gk. cyklos = circular; stoma = mouth). Body eel-shaped, without scales, jaws and lateral fins. Mouth rounded and suctorial. Gills 5–16 pairs. Parasites and scavengers. 45 species. e.g. Lampreys (Petromyzon) and hagfishes (Myxine).

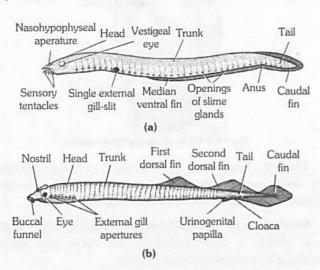

Fig: 1.7-59 (a) Myxine (b) Petromyzon

Division II. Gnathostomata : (Gk. gnathos = jaw; stoma = mouth). Jawed vertebrates having true jaws and paired limbs.

For convenience, some taxonomists further divide Gnathostomata division into two super classes. All the fishes like aquatic gnathostomes are placed in the superclass Pisces, whereas all the four-footed terrestrial gnathostomes in the superclass Tetrapoda. Their contrasting features are as follows:

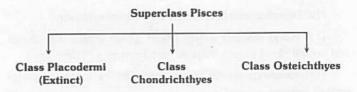

Superclass 1. Pisces

- (1) Exclusively aquatic gnathostome vertebrates.
- (2) Paired limbs, if present, as fins.
- (3) Median fins present
- (4) Skin usually moist and scaly
- (5) Respiration aquatic, by gills
- (6) Sense organs functional in water
- (7) It consist of fishes only.

Superclass 2. Tetrapoda

- (1) Aquatic or terrestrial. Some arboreal and aerial
- (2) Paired pentadactyle limbs present
- (3) Median fins absent
- (4) Skin usually dry and cornified
- (5) Respiration aerial, by lungs
- (6) Sense organs functional in air.
- (7) It consist of classes Amphibia, Reptilia, Aves and Mammals.

Superclass Pisces

Class 1. Chondrichthyes (The Cartilaginous Fishes)

(Gk. chondros = cartilage; ichthys = fish)

General characters.

- (1) Mostly marine and predaceous.
- (2) Body fusiform or spindle shaped.
- (3) Fins both median and paired, all supported by fin rays. Pelvic fins bear claspers in male. Tail heterocercal.
- (4) Skin tough containing minute placoid scales and mucus glands.
- (5) Endoskeleton entirely cartilaginous, without true bones. Notochord persistent. Vertebrae complete and separate. Pectoral and pelvic girdles present.
- (6) Mouth ventral. Jaws present. Teeth are modified placoid scales. Stomach J-shaped. Intestine with spiral valve.
- (7) Respiration by 5 to 7 pairs of gills. Gill-slits separate and uncovered (except, chimaeras). Operculum absent. No air bladder and lungs.
- (8) Heart 2-chambered (1 auricle and 1 ventricle). Sinus venosus and conus arteriosus present. Both renal and portal systems present. Temperature variable (poikilothermous or cold blooded or ectothermal animal.
- (9) Kidneys mesonephric or opisthonephric. Excretion ureotelic. Cloaca present.
- (10) Brain with large olfactory lobes and cerebellum. Cranial nerves 10 pairs.
- (11) Olfactory sacs do not open into pharynx. Membranous labyrinth with 3 semicircular canals. Lateral line system present.
- (12) Sexes separate. Gonads paired. Gonoducts open into cloaca. Fertilization internal. Oviparous or ovoviviparous. Eggs large, yolky. Cleavage meroblastic. Development direct, without metamorphosis.

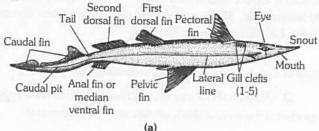

Classification of Chondrichthyes

- (a) Subclass I. Selachii: (Gk., selachos, a shark)
- Multiple gill slits on either side protected by individual skin flaps.
 - (2) A spiracle behind each eye.
 - (3) Cloaca present.

Examples: True sharks. Dogfishes (Scoliodon, Chiloscyllium, Mustelus, Carcharinus), spiny dogfish (Squalus) seven gilled shark (Heptanchus), Stegostoma, Sphyrna, Rhineodon. Skates and rays. Skate (Raja) Trygon, Torpedo, Myliobatis, Rhinobatus, Pristis.

☐ Zebra shark (Stegostoma) is the most beautiful fish in the sea.

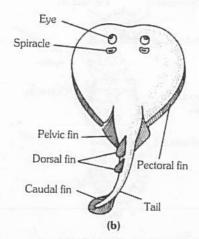

Fig: 1.7-60 (a) Scollodon (b) Torpedo

- (b) Subclass II. Holocephali : (Gk., holos, entire + kephale, head)
- Single gill opening on either side covered by a fleshy operculum.
 - (2) No spiracles, cloaca and scales.
 - (3) Jaws with tooth plates.
 - (4) Single nasal opening.
- (5) Lateral line system with open groove. It serves to detect waves in water current.

Examples: Hydrolagus (= Chimaera).

Class 2. Osteichthyes-(The Bony fishes)

(Gk. osteon = bone; ichtyes = fish)

General Characters

- (1) Inhabit all sorts of water-fresh, brackish or salt; warm or cold.
 - (2) Body spindle-shaped and streamlined.
- (3) Fins both median and paired, supported by fin rays of cartilage or bone. Tail usually homocercal.
- (4) Skin with may mucus glands, usually with embedded dermal scales of 3 types; ganoid, cycloid or ctenoid. Some without scales. No placoid scales.
- (5) Endoskeleton chiefly of bone. Cartilage in sturgeons and some other. Notochord replaced by distinct vertebrae Pelvic girdle usually small and simple or absent. Claspers absent.

- (6) Mouth terminal or sub terminal. Jaws usually with teeth. Cloaca lacking, anus present.
- (7) Respiration by 4 pairs of gill on body gill arches, covered by a common operculum on either side.
- (8) An air (swim) bladder often present with or without duct connected to pharynx. Lung-like in some (Dipnoi).
- (9) Ventral heart 2-chambered (1 auricle + 1 ventricle). Sinus venosus and conus arteriosus present. Aortic arches 4 pairs. Erythrocytes oval, nucleated. Temperature variable (poikilothermous).
 - (10) Adult kidneys mesonephric. Excretion ureotelic.
- (11) Brain with very small olfactory lobes, small cerebrum and well developed optic lobes and cerebellum. Cranial nerves 10 pairs.
- (12) Well developed lateral line system. Internal ear with 3 semicircular canals.
- (13) Sexes separate. Gonads paired. Fertilization usually external. Mostly oviparous, rarely ovoviviparous or viviparous. Eggs minute to 12 mm. Cleavage meroblastic. Development direct, rarely with metamorphosis.

Classification of Osteichthyes

- (a) Subclass I. Sarcopterygii : (Gk., sarcos = fleshy; pterygium = fin)
- Paired fins leg-like or lobed. With a fleshy, bony central axis covered by scales.
- (2) Dorsal fins 2. Caudal fin heterocercal with an epichordal lobe.
- (3) Olfactory sacs usually connected to mouth cavity by internal nostrils or choanae, hence the previous name of subclass, choanichthyes (Gk. *choana* = funnel; *ichthyes* = fish).
- (4) Popularly called fleshy or lobe-finned, or air breathing fish. Divided into 2 superorders or orders: Crossopterygii and Dipnoi.

Order 1. Crossopterygii: (Gk. crossoi = a fringe; pteryx = fin)

- (1) Paired fins lobate. Caudal fin 3-lobed.
- (2) Premaxillae and maxillae present.
- (3) Internal nares present or absent. Spiracles present.
- (4) Air bladder vestigeal.

Example: Primitive fleshy-finned extinct fishes. Single living genus Latimeria.

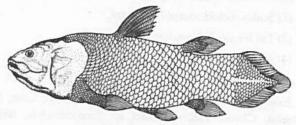

Fig: 1.7-61 Latimeria

Order 2. Dipnoi: (Gk. di = double; pnoe = breathing)

- (1) Median fins continuous to form diphycercal tail.
- (2) Premaxillae and maxillae absent.
- (3) Internal nares present and spiracles absent.
- (4) Air bladder single or paired, lung-like

Examples: Lung fishes. Only 3 living genera: Epiceratodus (Neoceratodus), Protopterus and Lepidosiren

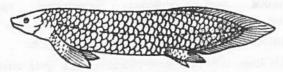

Fig: 1.7-62 Neoceratodus

- (b) Subclass II. Actinopterygii : (Gr. actis = ray; pteryx = fin)
- (1) Paired fins thin, broad, without fleshy basal lobes, and supported by dermal fin rays.
 - (2) One dorsal fin, may be divided.
 - (3) Caudal fin without epichordal lobe.
 - (4) Olfactory sacs not connected to mouth cavity.
- (5) Popularly called ray-finned fishes. Divided into 3 infraclasses or superorders: Chondrostei, Holostei and Teleostei.

Superorder A. **Chondrostei**: (Gk. chondros = cartilage; osteon = bone)

- (1) Mouth opening large.
- (2) Scales usually ganoid.
- (3) Tail fin heterocercal.
- (4) Primitive ray-finned fish or cartilaginous ganoids.

Examples: Acepenser (Sturgeon), Polyodon (paddlefish)

Superorder B. **Holostei**: (Gk. holos = entire; osteon = bone)

- (1) Mouth opening small.
- (2) Ganoid or cycloid scales.
- (3) Tail fin heterocercal.
- (4) Intermediate ray-finned fish, transitional between Chondrostei and Teleostei

Examples: Lepisosteus (garpike)

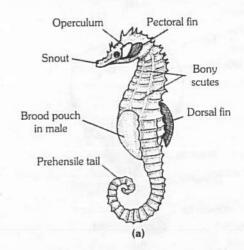

Superorder C. **Teleostei** – (Gk. *teleos* = complete; *osteon* = bone)

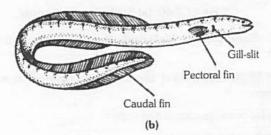

- (1) Mouth opening terminal, small.
- (2) Scales cycloid, ctenoid or absent.
- (3) Tail fin mostly homocercal.
- (4) A hydrostatic swim bladder usually present.
- (5) Advanced or modern ray-finned fishes

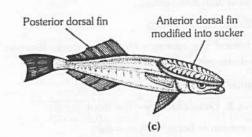

Examples – Harpodon, Cyprinus, Labeo rohita, Catla, Botia, Carassius, Clarius, Heteropneustes or Saccobranchus, Wallago, Mystus, Electrophorus, Anguilla, Muraena (moray) Hemirhamphus

(half beak), Belone (garfish), Hippocampus (sea horse), Syngnathus, Fistularia Ophiocephalus or channa Amphipbnous, Symbranchus. Mastacembelus, Macrognathus, Pterois, Pleuronectes, Synaptura, Solea, Echeneis or Remora, Tetrodon

- ☐ Hippocampus (Sea horse) shows parental care. On the belly of male is a brood pauch for incubating eggs.
- Remora (Echeneis) has modified dorsal fin into a sucker. It attaches to the body of shark, whales, etc. (commensalism).

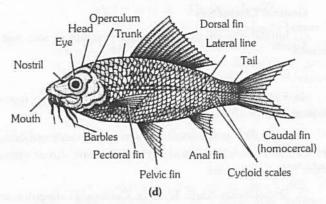

Fig. 1.7-63 : (a) Hippocampus (b) Anguilla (c) Echeneis (d) Labeo

Table: 1.7-10 Common Names

Cartilaginous Fisher	S	
Scoliodon	-	Dogfish (Shark)
Stegostoma	-	Zebra shark (Tigerfish)
Trygon	-	Sting ray
Torpedo		Electric ray
Rhinobatus	-	Guitar fish
Pristis	_	Sawfish
Chimaera	-	Rat fish
Bony Fishes		
Clarius	_	Catfish
Echeneis	-	Sucker fish
Hippocampus	_	Sea horse
Gambusia	_	Mosquito fish
Exocoetus	-	Flying fish
Tetradon		Globe fish
Diodon		Porcupine fish
Cyanoglossus	-	Flatfish
Anabas	-	Climbing fish
Labeo rohita		Indian carp
Syngnathus	-	Pipe fish
Fistularia	-	Flute fish
Carassius	_	Goldfish
Anguilla	-	Freshwater eel
Oncorhynchus	-	Pacific salmon

Table: 1.7-11 False Fishes

Common Names	Genus	Phylum	
1. Jellyfish	Aurelia	Coelenterata	
2. Silverfish	Lepisma	Arthropoda	
3. Crayfish	Astacus	Arthropoda	
4. Razorfish	Solen	Mollusca	
Cuttlefish	Sepia	Mollusca	
6. Devilfish	Octopus	Mollusca	
7. Starfish	Asterias	Echinodermata	
8. Hagfish	Myxine	Chordata	

Class Amphibia – The vertebrates with Dual life

(Gk. Amphi = both; bios = Life)

General characters

- Aquatic or semi aquatic (freshwater), air and water breathing, carnivorous, cold-blooded, oviparous, tetrapod vertebrates.
- (2) Head distinct, trunk elongated. Neck and tail may be present or absent.
- (3) Limbs usually 2 pairs (tetrapod), some limb less toes 4-5 (pentadactyle) or less. Paired fins absent. Median fins, if present, without fin rays.
- (4) Skin soft, moist and glandular. Pigment cells (chromatophores) present.
- (5) Exoskeleton absent. Digits claw less. Some with concealed dermal scales.

- (6) Endoskeleton mostly bony. Notochord does not persist. Skull with 2 occipital condyles. i.e. Dicondylic skull.
- (7) Mouth large. Upper or both jaws with small homodont teeth. Tongue often protrusible. Alimentary canal terminates into cloaca.
- (8) Respiration by lungs, skin and mouth lining. Larvae with external gills which may persist in some aquatic adults.
- (9) Heart 3-chambered (2 auricles + 1 ventricle). Sinus venosus present. Aortic arches 1-3 pairs. Renal and hepatic portal systems well developed Erythrocytes large, oval and nucleated. Body temperature variable (poil:ilothermous).
- (10) Kidneys mesonephric. Urinary bladder large. Urinary ducts open into cloaca. Excretion ureotelic.
 - (11) Brain poorly developed. Cranial nerves 10 pairs.
- (12) Nostrils connected to buccal cavity. Middle ear with a single rod-like ossicle, columella. Larval forms and some aquatic adults with lateral line system.
- (13) Sexes separate. Male without copulatory organ Gonoducts open into cloaca. Fertilization mostly external. Females mostly oviparous.
- (14) Development indirect. Cleavage holoblastic but unequal. No extra-embryonic membranes. Larva a tadpole which metamorphoses into adult.

Classification of Amphibia: The living amphibians belong to only 2,500 species, a very much smaller number than that of other principal classes of vertebrates. Ranging from mid-Palaeozoic (Devonian) to early Mesozoic (Triassic). They dominated the World during Carboniferous, but most of them have become extinct since long. The classification most generally followed nowadays was provided by G. Kingsley Noble (1924).

(a) Subclass I. Stegocephalia (Extinct): Limbs pentadactyle. Skin with scales and bony plates. Skull with a solid bony roof leaving openings for eyes and nostrils. Permian to Triassic.

Fig: 1.7-64 Stegocephalia

Order 1. **Labyrinthodontia**: Oldest known tetrapods called stem Amphibia. Carboniferous to Triassic.

Example: Eryops.

Order 2. **Phyllospondyli** : Small salamander-like. Carboniferous to permian.

Example: Branchiosaurs (Ichthyostega).

Order 3. **Lepospondyli** : Small salamander or eellike.Carboniferous to Permian.

Examples - Diplocaulus, Lysorophus.

(b) Subclass II. Lissamphibia (living): Modern Amphibia lacking dermal bony skeleton. Teeth small, simple.

Order 1. Gymnophiona or Apoda: (Gk. gymnos = naked; ophioneos = serpet-like).

(1) Limb less, blind, elongated worm like, burrowing tropical forms known as caecilians or blind worms.

- (2) Tail short or absent, cloaca terminal.
- (3) In some dermal scales embedded in skin which is transversely wrinkled.
- (4) Skull compact, roofed with bone.
 - (5) Limb girdle absent.
- (6) Males have protrusible copulatory organs,

 Ichthyophis is a Limb less amphibian showing parental care. It has no tongue.

Order 2. Urodela or Caudata: (Gk. Ura = tail; delos = visible) or (L. = cauda = tail). Nostril

- (1) Lizard-like amphibians with a distinct tail.
- (2) Limbs 2 pairs, usually weak, almost equal.
- (3) Skin devoid of scales and tympanum.
- (4) Gills permanent or lost in adult.
- (5) Males without copulatory organs.
- (6) Larvae aquatic, adult-like, with teeth.
- (7) It mainly includes Newts and Salamanders.

Examples: Cryptobranchus, Megalobatrachus, Ambystoma, Desmognathus, Salamandra, Plethodon. Amphiuma, Pseudobranchus, Triturus, Necturus.

The main difference between gymnophiona and urodela is that urodela have smooth moist skin.

Order 3. Salientia or Anura: (L., saliens = leaping) or (Gk., an = without; nura = tail)

- (1) Specialized amphibia without tail in adults.
- (2) Hind limbs usually adapted for leaping and swimming.
- (3) Adults without gills or gill openings.
- (4) Eyelids well-formed. Tympanum present.
- (5) Skin loosely-fitting, scale less; mandible toothless.
- (6) Pectoral girdle bony. Ribs absent or reduced. Vertebral column very small of 5-9 pre sacral vertebrae and a slender urostyle.

Examples: Alytes, Bombinator, Discoglossus, Pipa, Xenopus,

Pelobates, Scaphiopus, Bufo, Rhinoderma, Dendrobates, Hyla,

Bombinator is famous for warning colouration.

(7) Fertilization always external.

(9) It mainly includes frogs and toads.

Gastrotheca, Rana, Polypedates or Rhacophorus.

Bufo is a poisonous amphibian.

(8) Fully metamorphosed without neotenic forms.

Class Reptilia -The creeping vertebrates

(L. reptare = to creep)

General Characters

- Predominantly terrestrial, creeping or burrowing, mostly carnivorous, air-breathing, cold-blooded, oviparous and tetrapodal vertebrates.
- (2) Body bilaterally symmetrical and divisible into 4 regionshead, neck, trunk and tail.
- (3) Limbs 2 pairs, pentadactyle. Digits provided with horny claws. However, limbs absent in a few lizards and all snakes.
- (4) Exoskeleton of horny epidermal scales, shields, plates and scutes.
 - (5) Skin dry, cornified and devoid of glands.
- (6) Mouth terminal. Jaws bear simple conical teeth. In turtles teeth replaced by horny beaks.
 - (7) Alimentary canal terminates into a cloacal aperture.
- (8) Endoskeleton bony. Skull with one occipital condyle (monocondylar). A characteristic T-shaped inter clavicle present.
- (9) Heart usually 3-chambered, 4-chambered in crocodiles. Sinus venosus reduced. 2 systemic arches present. Red blood corpuscles oval and nucleated. Cold-blooded.
 - (10) Respiration by lungs throughout life.
 - (11) Kidney metanephric. Excretion uricotelic.
- (12) Brain with better development of cerebrum than in Amphibia. Cranial nerves 12 pairs.
- (13) Lateral line system absent. Jacobson's organs present in the roof of mouth.
- (14) Sexes separate. Male usually with a muscular copulatory organ.
- (15) Fertilization internal. Mostly oviparous. Large yolky meroblastic eggs covered with leathery shells, always laid on land. Embryonic membranes (amnion, chorion, yolk sac and allantois) appear during development. No metamorphosis. Young resemble adults.
 - (16) Parental care usually absent

Classification of Reptilia: According to Bogert, there are more than 7,000 living and several extinct species of reptiles, grouped into approximately 16 orders of which only 4 are living.

 (a) Subclass I Anapsida – Primitive reptiles with a solid skull roof. No temporal openings.

Order 1. **Chelonia or Testudinata**: (Gk. *chelone* = turtle) or (L. *testudo* = turtle)

- (1) Body short, broad and oval.
- (2) Limbs clawed and/or webbed, paddle-like.
- (3) Body encased in a firm shell of dorsal carapace and ventral plastron, made of dermal bony plates. Thoracic vertebrae and ribs usually fused to carapace.
- (4) Skull anapsid, with a single nasal opening and without a parietal Foramen. Quadrate is immovable.
 - (5) No sternum is found.
 - (6) Teeth absent. Jaws with horny sheaths.

- (7) Cloacal aperture a longitudinal slit.
- (8) Heart incompletely 4-chambered with a partly divided ventricle.
 - (9) Copulatory organ single and simple.
- (10) About 400 species of marine turtles, freshwater terrapins and terrestrial tortoises.

Examples : Chelone, Chrysemys, Testudo, Trionyx, Dermochelys.

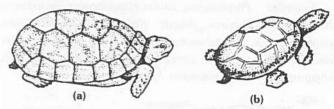

Fig: 1.7-68 (a) Giant tortoise, (b) Snake necked turtle

- (b) Subclass II Euryapsida (extinct): Skull with a single dorso-lateral temporal opening on either side bounded below by postorbital and squamosal bones.
- (c) Subclass III Parapsida (extinct): Skull with a single dorso-lateral temporal opening on either side bounded below by the supra temporal and post frontal bones.
- (d) Subclass IV Synapsida (extinct): Skull with a single lateral temporal opening on either side bounded above by the postorbital and squamosal bones.
- (e) Subclass V Diapsida (Living): Skull with two temporal openings on either side separated by the bar of postorbital and squamosal bones.

Order 2. Rhynchocephalia: (L. rhynchos = snout; Gk. kephale = head)

- (1) Body small, elongated, lizard-like.
- (2) Skull diapsid. Parietal foramen with vestigeal pineal eye present. Quadrate is fixed.
- (3) Vertebrae amphicoelous or biconcave. Numerous abdominal ribs present.
 - (4) Teeth acrodont. Cloacal aperture transverse.
 - (5) Heart incompletely 4-chambered.
 - (6) No copulatory organ is male.

Example: Represented by a single living species, the "Tuatara" or Sphenodon punctatum of New Zealand.

☐ Sphenodon is referred to a "living fossil" because it has retained many primitive characteristics of fossil or stem reptiles.

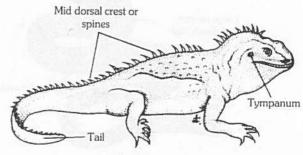

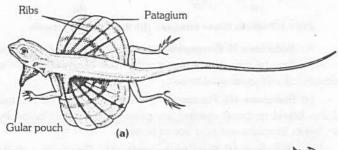

Fig: 1.7-69 Tuatara

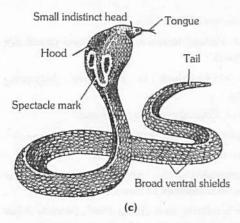

Order 3. Squamata: (L. squama = scale or squamatus = scaly)

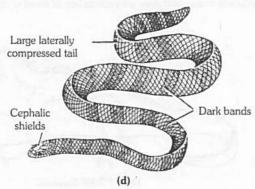

- (1) Advanced, small to medium, elongated.
- (2) Skull diapsid. Quadrate movable.
- (3) Vertebrae procoelous. Ribs single headed.
- (4) Heart incompletely 4-chambered.
- (5) Cloacal aperture is transverse.
- (6) It includes snakes and lizards.

Examples: Phrynosoma, Draco Hemidactylus, Heloderma, Chameleon, Ophisaurus, Anguis, Rhineura, Barkudia Geko, Iguana, Varanus komodoeusis, Python, Typhlops, Eryx johuii, Naja, Bungarus caeruleus, Dryophis, Vipera russelli. Hydrophis, Enhydrina, Crolatus, Ancistrodon, Micrurus, Lachesis, etc.

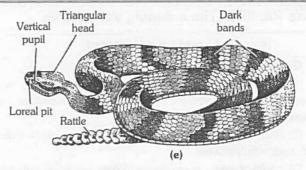

Fig: 1.7-70 (a) Draco (b) Phrynosoma (c) Indian cobra-Naja naja (d) Sea snake-Hydrophis (e) Rattle snake Crotalus horridus

Order 4. Crocodilia: (Gk. krokodeilos = Crocodile)

- (1) Skin thick with scales bony plates and scutes.
- (2) Skull diapsid. Quadrate immovable. No parietal foramen. A pseudopalate present. Pineal gland absent.
 - (3) Ribs bicephalous. Abdominal ribs present.
 - (4) Heart completely 4-chambered.
 - (5) Cloacal aperture is a longitudinal slit.

Examples: Crocodylus, Gavialis, Alligator

☐ The lung cavity of crocodile is separated from rest of body cavity by a muscular diaphragm, analogous to that of mammals.

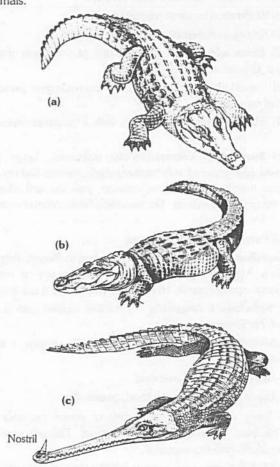

Fig: 1.7-71 (a) Crocodylus palustris (Indian freshwater crocodile) (b) Alligator missisiplensis (American alligat) (c) Gavialis gangeticus (Gavial or gharial)

Table: 1.7-13 Common Names

Table :	1.7-13	Common Names
Testudo	-	Tortoise
Dermochelys	-	Leather back turtle
Trionyx	-	Soft shelled turtle
Chelonia mydas	-	Green turtle
Kachuga	-	Terrapin
Sphenodon	-	Tuatara
Crocodylus	-	Maggar
Alligator	-	Alligator
Gavialis	-	Gharial
Lizards		
Hemidactylus	-	Wall/house lizard
Uromastix	-	Spiny tailed lizard
Calotes	-	Garden lizard
Draco	-	Flying dragon
Phrynosoma	-	"Horned toad"
Mabouia	-	Skink
Varanus	-	Monitor lizard
Heloderma	-	Gila monster
		Beaded lizard
Ophisaurus	-	Glass snake
Anguis	-	Slow worm
		Blindworm
Rhineura	-	Worm lizard
Iguana	-	Collared lizard
Snakes (Nonpoiso	nous)	
Typhlops	-	Blind snake
Ptyas (Zamenis)	-	Rat snake
Tropidonotus	-	Grass snake
		Pond snake
Lycodon	-	Wolf snake
Dendrophis	-	Tree snake
Dryophis	-	Whip snake
Eryx johnii	-	Sand Boa
Snakes (Poisonous	s)	
Naja naja	-	Cobra
Naja hannah	-	King cobra
Bungarus	-	Krait
Viper russelli	_	Pitless viper
Ancistrodon	-	Pit viper
Crotalus	-	Rattle snake
Hydrophis '	_	Sea snake
Enhydrina	-	Sea snake
Micrurus		Coral snake

Class Aves - The Birds

(L. avis = bird) or (Gk. ornis = bird)

General Characters

- Feather-clad, air-breathing, warm-blooded, oviparous, bipedal flying vertebrates.
- (2) Limbs are two pairs. Forelimbs are modified as wings for flying. Hind limbs or legs are large, and variously adapted for walking, running scratching, perching, food capturing, swimming or wading, etc.
 - (3) Exoskeleton is epidermal and horny.
- (4) Skin is dry and devoid of glands except the oil or preen gland at the root of tail.
 - (5) Pectoral muscles of flight are well developed.
- (6) Skull smooth and monocondylic, bearing a single occipital condyle. Cranium large and dome-like. Sutures indistinct.
- (7) Vertebral column short. Centra of vertebrae heterocoelous (saddle-shaped).
- (8) Sternum large, usually with a vertical, mid ventral keel for attachment of large flight muscles.
- (9) Ribs double-headed (bicephalous) and bear posteriorly directed uncinate processes.
- (10) Both clavicles and single inter clavicle fused to form a Vshaped bone, called furcula or wishbone or merry-thought bone.
- (11) Heart completely 4-chambered. There are neither sinus venosus or truncus arteriosus. Only right aortic (systemic) arch persists in adult. Renal portal system vestigeal. Blood corpuscles nucleated.
- (12) Birds are the first vertebrates to have warm blood. Body temperature is regulated (homoiothermous).
- (13) Respiration by compact, spongy, nondistensible lungs continuous with thin air-sacs.
- (14) Larynx without vocal cords. A sound box or syrinx, producing voice, lies at or near the junction of trachea and bronchi.
- (15) Kidneys metanephric and 3-lobed. Ureters open into cloaca. Urinary bladder absent. Birds are urecotelic. Excretory substance of urates eliminated with faeces.
- (16) Sexes separate. Sexual dimorphism is well marked in some birds like peacock and parrot.
- (17) Fertilization internal, preceded by copulation and courtship. Females oviparous.
- (18) Eggs develop by external incubation. Cleavage discoidal, meroblastic. Development direct, Extra-embryonic membranes (amnion, chorion, allantois and yolk-sac) present (Amniota).
 - (19) Parental care is well marked.

Classification of Aves: Birds show less diversification than any other group of vertebrate animals. 25 to 30 avian orders are recognized depending on the taxonomist. Class Aves is first divided into two subclasses.

- (a) Sub-Class I. Archaeornithes : (Gk. archios = ancient; ornithos = bird)
- (1) Extinct, archaic, Jurassic birds of Mesozoic Age, about 155 million years ago.
 - (2) Wings primitive, with little power of flight.
 - (3) Vertebrae amphicoelous.
 - (4) Sternum without a keel.
- (5) Thoracic ribs slender, without uncinate processes. In Archacopteryx beak in toothed.

This sub-classes includes a single order

Order Archaeopterygiformes: Example: Archaeopteryx lithographica, from Jurassic or Bavaria, Germany; one specimen lying in the British museum, London, the other lying in the Berlin.

- (b) Sub-class II. Neornithes: (Gk. neos = modern; ornithos = Birds)
 - (1) Modern as well as extinct post-Jurassic birds.
- (2) Wings usually well-developed and adapted for flight, with few exceptions.
 - (3) Teeth absent except in some fossil birds.
 - (4) Vertebrae heterocoelous in living forms.
 - (5) Sternum usually with a keel.
 - (6) Thoracic ribs usually with uncinate processes.
 - (7) Abdominal ribs absent

This sub-class is divisible into 4 super-orders:

Super-order 1. Odontognathae: (Gk. odontos = teeth)

- (1) Extinct, Upper Cretaceous birds.
- (2) Jaws bear teeth, "so advantageous for catching fish".

Order 1. Hesperornithiformes

Example - Hesperornis, Enaliornis, Baptornis, etc.,

Order 2. Ichthyornithiformes

Examples - Ichthyornis, Apatornis.

Super-order 2. Palaeognathae or Ratitae: (Gk. palaios = old; gnathos = jaw) or (L. ratis = raft).

- (1) Modern big-sized, flightless, running birds, without teeth.
- (2) Wings vestigeal or rudimentary; feathers devoid of interlocking mechanism.
 - (3) Rectrices absent or irregularly arranged.
 - (4) Oil gland is absent, except in Tinamus and Kiwi.
- (5) Skull is dromaeognathous or palaeognathous that is, vomer is large and broad and interpolated between palatines.
 - (6) Sternal keel vestigeal, absent or flat, raft-like.
 - (7) Uncinate processes are vestigeal or absent.
 - (8) Clavicles are small or absent.
 - (9) Pectoral muscles poorly developed.
 - (10) Syrinx is absent

The flightless birds or ratites are not represented in India. They are grouped in 7 orders as follows;

Order 1. Struthioniformes: (Gk. struthio = ostrich + form)

- (1) Legs strongly developed, each with two toes (3rd and 4th) with stunted nails.
 - (2) Pubes form a ventral symphysis.

Examples: True ostriches (Struthio camelus) of Africa and western Asia (Arabia).

Order 2. Rheiformes: (Gk. Rhea = mother of Zeus + form)

Examples: American ostriches or common rhea (Rhea americana) represented by two species in South American pampas; Darwin's rhea (Pteroncemia pennata).

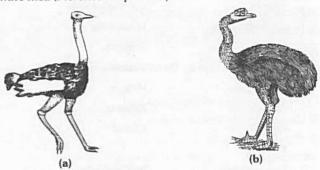

Fig: 1.7-72 (a) Ostrich (b) Rhea

Order 3. Casuariformes

Examples: Cassowaries (Casuarius) of australia, and New Guinea and Emus (Dromaius novaehollandiae) of New Zealand.

Order 4. Apterygiformes

Examples: Kiwis (Apteryx) of New Zealand.

Order 5. Dinornithiformes

Examples: Moas (Dinornis maximus) of New Zealand

Order 6. Aepyornithiformes

Examples: Giant Elephant-birds (Aepyornis titan) Mulleornis of Africa and Madagascar.

Order 7. Tinamiformes

Examples: Tinamou (Tinamus), Eudromia

Super-order 3. Impennae

Order 1. Sphenisciformes

Examples: Penguins (Aptenodytes) Southern Hemisphere.

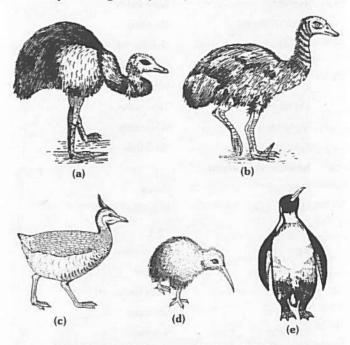

Fig: 1.7-73 (a) Cassowary (b) Emus (c) Tinamou (d) Kiwi (e) Penguin

Super order 4. Neognathae

- (1) Most modern, usually small-sized. Flying birds.
- (2) Wings well-developed; feathers with interlocking mechanism.
 - (3) Rectrices present and arranged regularly.
 - (4) Pterylae are regular.
 - (5) Oil gland is present.
- (6) Skull is neognathous, that is, vomer is short allowing palatines to meet.
 - (7) Sternum with a well-developed keel.
 - (8) Uncinate processes are present.
 - (9) Pygostyle is present

The super-order Neognathae includes several orders. For the sake of study they may be grouped into at least 6 homogenous ecological groups, as follows:

Group A. Arboreal Birds: Under this group may be placed the majority of birds spending most of their lives in and around shrubs and trees.

Order 1. **Passeriformes** : (L. passer = sparrow + form)

This is the largest of all the bird orders including half of the known species. Feet are adapted for perching, while beaks are adapted for cutting.

Fig: 1.7-74 House sparrow

Examples: Passer domesticus, Corvus splendens, common myna (Acridotheres tristis).

Order 2. **Piciformes**: (L. *picus* = wood pecker + form) It includes woodpeckers, toucans, sap-suckers and their allies.

Examples: Yellow fronted pied woodpecker (Dendrocopos mahrattensis).

Order 3. **Columbiformes** : (L. = columba = dove + form) It includes doves and pigeons.

Examples: Blue rock pigeon (Columba livia). Green pigeon (Crocopus), extinct dodo (Raphus).

Order 4. Psittaciformes: (L. = psitacus = parrot + form)

It includes parrots, parakeets, cockatoos, macaws, love-birds, etc., denizens of the equatorial jungles.

Examples : Large Indian parakeet (Psittacula eupatria), green parrot (psittacula krameri).

Fig: 1.7-75 Parrot

Group B. Terrestrial Birds: These birds are perfectly able to fly but spend most of their time walking or running on ground.

Order 5. **Galliformes**: (L. gallus = a cock + form) It includes gamebirds notable for their palatability, massive scratching feet, short and powerful flight and largely graminivorous diet.

Examples: Red jungle fowl (Gallus), peafowl (Pavo cristatus).

Fig: 1.7-76 Peacock

Order 6. **Cuculiformes**: (L. = cuculus = cuckoo + form) It includes cuckoos and their allies.

Examples: Cuckoo (Cuculus canorus), Koel (Eudynamis scolopaeous), Crow-pheasant (Centropus sinensis).

Group C. Swimming and Diving Birds

Order 7. **Anseriformes**: (L. *anser* = goose + form) Aquatic birds such as geese, swans and ducks belong to this order.

Examples: Wild duck or mallard (Anas), common teal (Nettion crecca), bar-headed goose (Anser indica)

Order 8. **Coraciiformes**: (Gk. korax = crow or raven + form) It includes kingfishers and their allies.

Examples: White breasted kingfisher (Halcyon smyrnensis), pied kingfisher (Ceryle rudis), bee eater (Hoopoe).

Fig: 1.7-77 Hoopoe

Order 9. **Gaviformes**: (L. gavia = sea mew + form) It includes marine birds, called loons (gavia) represented by only four species.

Order 10. **Podicipediformes or Colymbiformes** (Gk. *kolymbos* = diving bird).

It includes grebes (Podicipes), often called divers because of their habits.

Order 11. **Procellariformes** (L. *Procella* = a tempest + form).

It includes tube-nosed, long and oily winged seabirds such as albatrosses (Diomedea), Petrels (Procellaria), shearwaters.

Order 12. **Pelecaniformes**: (L. *pelicanus* = pelican + form) It includes pelicans, darters, gannets and cormorants.

Examples : Pelicans (Pelecanus), little cormorant (Phalacrocorax niger)

Group D. Shore Birds and Wading Birds

These aquatic birds seldom swim or dive beneath the water to any great extent.

Order 13. **Charadriiformes**: (NL. charadrius = genus of plovers + form) This order includes a rather diverse group of water frequenting shore birds characterized by long wading legs, webbed toes and mudprobing beaks.

Examples: Red wattled lapwing (Lobivanellus indicus)

Order 14. Ciconiiformes: (L. ciconia = a stork + form)

It includes long-legged, marshy wading birds with long snake-like neck and javelin or pincer-like beak for piercing their aquatic prey.

Examples: Cattle egret (Bubulcus ibis), heron (Ardea herodias), spoonbil (Platalea leucorodia), strok (Ciconia), flamingo (Phonicopterus).

Order 15. **Gruiformes**: (L. grus = crane + form) It includes crane-like wading birds with long legs and partially webbed feet.

Examples: Common coot (Fulica atra),

Group E. Birds of Prev

Order 16. Falconiformes: (L. falco = falcon + form)

The diurnal birds of prey with sharp hooked beaks and strong curved claws.

Table: 1.7-14 Flightless Birds

Genus	Distribution	
Struthio	Africa and Arabia	
Rhea	South America	
Casuarius	Australia and New Guinea	
Dromaius	Australia	
Tinamus	South America	
Apteryx	New Zealand	
	Struthio Rhea Casuarius Dromaius Tinamus	

Table: 1.7-15 Types of Beaks in Birds

	Туре	Example
1.	Seed eating	Sparrow
2.	Cutting	Crow
3.	Fruit eating	Parrot
4.	Insect eating	Ноорое
5.	Fish eating	Kingfisher
6.	Flower probing	Humming bird
7.	Spatulate	Spoonbill
8.	Water and mud straining	Duck
9.	Tearing and piercing	Eagle and owl

Table: 1.7-16 Types of Feet in Birds

Mar.	Туре	Example
1.	Perching	Sparrow
2.	Raptorial	Owl
3.	Scratching	Fowl
4.	Swimming	Duck
5.	Running or cursorial	Ostrich
6.	Climbing and clinging	Woodpecker
7.	Wading	Jacana and Heron

Table: 1.7-17 Common Names

Passer domesticus	-	House sparrow
Corvus splendens	-	House crow
Eudynamis scolopaceus	-	Koel
Upupa epops	-	Ноорое
Pseudogyps bengalensis	-	Bengal vulture
Psittacula eupatria	-	Indian parrot
Psittacula krameri	=	Rose ringed parakeet
Phoenicopterus roseus	-	Flamingo
Pavo cristatus	-	Peacock or Mor
Milvus migrans	-	Kite
Bubo bubo	-	Great horned owl
Dinopium benghalensis	-	Woodpecker .
Columba livia	_	Common rock pigeon

Class-Mammalia

(L. mamma = breast)

General characters

- (1) Hair-clad, mostly terrestrial, air-breathing, warm blooded, viviparous, tetrapod vertebrates.
- (2) Limbs 2 pairs, pentadactyle, each with 5 or fewer digits. Hind limbs absent in cetaceans and sirenians.
- (3) Exoskeleton includes lifeless, horny, epidermal hairs, spines, scales, claws, nails, hoofs, horns, bony dermal plates, etc.
- (4) Skin richly glandular containing sweat, sebaceous (oil) and sometimes scent glands in both the sexes. Females also have mammary glands with teats producing milk for suckling the young.
- (5) Endoskeleton thoroughly ossified. Skull dicondylic having 2 occipital condyles. Cranium large. A single zygomatic arch present. Pterygoids small, scale-like. Otic bones fused into periotic which forms tympanic bulla with tympanic. Each half of lower jaw made of a single bone, the dentary, articulating with squamosal of skull Vertebrae with terminal epiphyses and flat centra (acoelous). Cervical vertebrae usually 7. Ribs bicephalous. Coracoid vestigial.
- (6) Teeth are of several types (heterodont), borne is sockets (thecodont) and represented by two sets (diphyodont).
- (7) Respiration always by lungs (pulmonary). Glottis protected by a fleshy and cartilaginous epiglottis. Larynx contains vocal cords.
 - (8) Heart 4-chambered with double circulation.
 - (9) Kidneys metanephric.
- (10) Brain highly evolved. Both cerebrum and cerebellum large and convoluted. Optic lobes small and 4 in number called corpora quadrigemina. Corpus callosum present connecting both cerebral hemispheres. Cranial nerves 12 pairs.
- (11) Senses well developed. Eyes protected by lids, the upper of which is movable. External ear opening protected by a large fleshy and cartilaginous flap called pinna. Middle ear cavity with 3 ear ossicles-malleus, incus and stapes. Cochlea of internal ear spirally coiled.
 - (12) Sexes separate.
 - (13) Fertilization internal preceded by copulation.
- (14) Except egg-laying monotremes, mammals are viviparous, giving birth to living young ones.
 - (15) Development uterine.

Classification of Mammalia: Mammals have been thoroughly described and adequately classified. The main characters forming the basis of their classification into orders include:

- (1) Mode of caring of their young,
- (2) Nature of dentition
- (3) Foot posture,
- (4) Nails, claws and hoofs,
- (5) Complexity of nervous system and
- (6) Systematics.
- (a) Subclass I prototheria : (Gk. protos = first ; therios = beast).
 - (1) Primitive, reptile-like, oviparous or egg-laying mammals.
 - (2) Mammary gland without nipples.

UNIVERSAL BOOK DEPOT 1960

- (3) External pinna absent.
- (4) Corpus callosum not found.
- (5) Adult without teeth, they bear horny beak.
- (6) Testes abdominal.
- (7) Female without uterus and vagina.

It has only one order:

Order **Monotremata**: (Gk. monos = single; trema = opening), Cloacal opening present Confined to Australian Tasmania and New Guinea region.

Examples: Monotremes. Platypus or duckbill (ornith orhynchus) spiny anteater (Tachyglossus = Echidna).

Fig: 1.7-79 (a) Echidna, (b) Ornithorhynchus

(b) Sub class II. Theria: (Gk. ther, = animal)

Subclass Theria is divided into two infraclasses : Metatheria and Eutheria.

Infraclass 1. Metatheria: (Gk. meta = between or after)

- (1) Metatherians are pouched mammals; young born in very immature state.
 - (2) Corpus collosum absent.
 - (3) Ovoviviparous.
 - (4) Epipublic bone present.
 - (5) Vagina and uterus are double.

Order 2. Marsupialia: (Gk. marsypion = pouch).

(1) Born in a very immature state, and complete their development attached to teats or nipples in the abdominal pouch or marsupium. (2) Usually 3 premolars and 4 molars in each jaw on either side. (3) Vagina double

Examples: Opossum (Didelphis). Kangaroo (Macropus), koala (Phascolarctos)

Kangaroo is the native of Australia.

Fig: 1.7-80 Kangaroo

Infraclass 2. Eutheria: (Gk. eu = true; therios; beast)

- (1) Higher viviparous placental mammals without marsupium.
- (2) Corpus callosum present in brain.
- (3) Nipples are present in mammary gland.
- (4) Young born in a relatively advanced stage.
- (5) Cloaca absent but anus present.
- (6) Dentition never exceeds $\frac{3.14.3}{3.14.3} = 44$. On the basis of

characteristics like skull, teeth and limbs, eutheria is arranged into 16 orders.

Order 1. Insectivora: (L. insectum = insect; vorare = to eat)

- (1) Small mammals with long pointed snout.
- (2) Feet plantigrade, usually 5-toed, with claws.
- (3) Molars with pointed, peg-like cusps for insect feeding.

Examples: Talpa, Sorex, Solenodon, Erinaceus, Paraechinus

Order 2. Dermaptera: (Gk. derm = skin; pteron = wing).

- (1) Nocturnal in trees.
- (2) A gliding mammal called flying lemur, resembling a flying squirrel. Membranous skin fold is present which help the animals in gliding from one tree to another.

Examples: One living genus Cynocephalos (= Galaeoithecus) with 2 species from South eastern Asia.

Order 3. Chiroptera: (Gk. Cheiros = hand; pteron = wing)

- Flying mammals or bats in which forelimbs are modified into wings.
 - (2) Hind legs short and included in wing membrane.
- (3) Second and third digits greatly longated supporting the skin fold forming the flight membrane.
 - (4) Eyes are small and vision weak.
 - (5) Ears have large pinnae.
 - (6) Radar system present.
 - (7) Nocturnal
- (8) These may be food eating, insect eating or blood sucking in feeding habit.

Examples: Pteropus, Rhinolophus, Desmodus

Order 4. **Edentata**: (L. edentatus = toothless) Teeth absent or reduced to molars. Without enamel. These are nocturnal and herbivorous. Testes are abdominal.

Examples: Myrmecophaga, Dasypus, Bradypus.

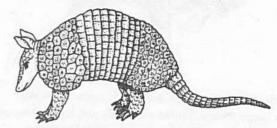

Fig: 1.7-81 Armadillo

Order 5. Pholidota: (Gk. pholis = a scale)

- (1) Body covered with large overlapping scales with sparse hair in between. No teeth,
 - (2) Tongue long and protrusible, used to capture insects.

Examples: Single genus of scaly anteaters pangolins (Manis)

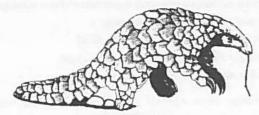

Fig: 1.7-82 Pangolin

Order 6. Rodentia: (L. rodo = gnaw).

- (1) Largest order including usually small gnawing mammals.
- (2) Each jaw with one pair of long, rootless, chisel-like incisors growing throughout life.
 - (3) Canine absent.

Examples: Rattus (House rat), Mus, Funambulus (Squirrel).

Order 7. Lagomorpha: (Gk. logos = hare; morphe = form)

With a second pair of small upper incisors behind first pair of large chisel like incisors. No canines.

Examples: Oryctolagus (Hare), Lepus (Rabbit), Ochotona.

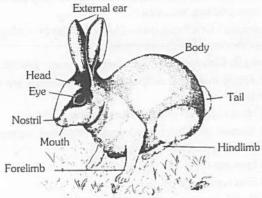

Fig: 1.7-83 Rabbit

Order 8. **Carnivora**: (L. caro = flesh; *vorare* = to eat) Small to large predatory, flesh-eating mammals.

Examples : Canis familiaris, C. lupus, C. aureus, Odobenus, Phoca, Panthera tigeris.

Fig: 1.7-84 Tiger

Order 9. Cetacea: (Gk. ketos or L. cetus = a whale)

- (1) Large marine fish-like mammals well adapted for aquatic life pectoral limbs modified into broad paddle-like flippers.
- (2) Tail divided in two broad horizontal fleshy flukes with a notch, used in propulsion.
 - (3) No claws, no hind limbs and no external ears.
- (4) Mostly gregarious and carnivorous. The living Cetacea are divided into two suborders Odontoceti (toothed whales) and Mysticeti or Mystacoceti (whalebone whales).

Examples: Phocaena, Orcinus (Killer whale), Delphinus (Dolphins), Platanista Physeter, Balenoptera (Blue whale).

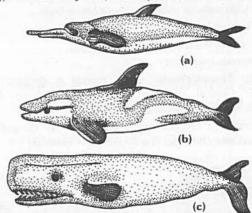

Fig: 1.7-85 (a) Dolphin, (b) Whale, (c) Sperm Whale

Order 10. Sirenia: (Gk. siren = sea nymph).

- (1) Large, clumsy herbivorous, aquatic mammals with paddlelike forelimbs, no hindlimbs and a flattened tail with horizontal lateral fleshy flukes with or without a notch.
 - (2) No external ears.
 - (3) Muzzle blunt. Hairs few.
 - (4) Stomach complex.
 - (5) Inhabit estuaries and coastal sea.

Examples: Trichechus (Manatees), Dugong (Halicore), recently extinct Steller's sea-cow (Rhytina).

Fig: 1.7-86 Manatee

Order 11. Tubulidentata: (L. tubulus Tube like; dens =

tooth) With tubular mouth tongue protrusible, no incisor or conines, limbs clawed and adapted for digging ant and termites nests.

Examples: Single genus of pig-like aardvark or Cape anteater (Orycteropus) of South Africa.

Fig: 1.7-87 Aardvark

Order 12. **Proboscidea :** (Gk. pro = in front; boskein = to eat)

- Largest living land animals having large heads, massive ears, thick practically hairless skins (pachyderm).
- (2) Bulky straight legs and 3 to 5 toes with small, nail like hoofs.

- (3) Conspicuous feature is the nose and upper lip modified as an elongated flexible proboscis or trunk. 2 upper incisors elongated as ivory tusks.
 - (4) Cheek teeth lophodont.

Examples: Elephas maximus (Indian elephant), Loxodonta africana (African elephant), Elephas cyclotis.

Order 13. Hyracoidea: (Gk. hyrax = shrew; eidos = form)

Small, guinea-pig like mammals distantly related to elephants. No canines. Cheek teeth lophodont.

Example: Hyrax (Procavia) from S. Africa, Syria and Arabia.

Order 14. **Perissodactyla**: (Gk. perissos = odd; *dactylos* = toes)

The odd-toed hoofed mammals or ungulates have an odd number of toes (1 or 3) incisors present in both jaws.

Examples : Equus cabalus (Horse), Equus asinus (Ass), Equus zebra (Zebra)

Order 15. Artiodactyla : (Gk. artios = even ; dactylos = digit)

- (1) The even-toed hoofed mammals having an even number of toes (2 or 4)
 - (2) Incisors and canines in upper jaw usually lacking.
 - (3) Stomach 4 chambered.
 - (4) Many with antlers or horns.

Examples : Sus, Hippopotamus amphibius, Camelus, Cervus, Moschus, Ovis.

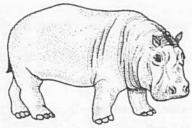

Fig: 1.7-88 Hippopotamus

Order 16. Primates: (L. primus = of the first rank)

- Generalized or primitive mammals except for the great development of brain.
 - (2) Mostly arboreal.
 - (3) First digit usually opposable, an adaptation for grasping.
 - (4) Eyes typically large and turned farward.

Example - Gibbon, Mandrillus, Chimpanzee, Ateles, etc.

Fig: 1.7-89 (a) Gibbon, (b) Chimpanzee

Table: 1.7-18 Common Names

_			mon rumes
	Canis familiaris	-	Dog
	Felis domestica	-	Cat
	Panthera leo	-	Lion
	Panthera tigris	-	Tiger
	Acinonyx jubatus	-	Cheetah
	Lutra	-	Otter
	Herpestes	-	Mongoose
	Trichechus	-	Manatee
	Halicore	-	Dugong
	Equus caballus	-	Horse
	Equus asinus	-1	Ass
	Rhinoceros unicornis	-	Indian rhinoceros
	Diceros bicornis	-	African rhinoceros
	Tapirus Indicus	-	Malayan Tapir
	Hippopotamus amphibius	-	Hippopotamus
	Camelus dromedarius	-	Arabian camel
	Cervus	-	Red deer
	Giraffa camelopardalis	-	Giraffe
	Sus scrofa	-	Wild boar
	Bubalus bubalis	-	Water buffalow
	Ateles paniscus	_	Spider monkey
	Macaca mulatta	-	Rhesus monkey
	Macaca silenus	_	Lion-tailed macaque
	Hylobates lar	_	Gibbon
	Papio		Baboon
	Presbytis	_	Langur
	Pongo	-	Orang-utan
	Pan	-	Chimpanzee

Tips & Tricks

- Pelagic animals: Animals living in open water and include both zooplanktons and nektons.
- Nektons are those animals which actively swim in open water while neustons are those animals which float or swim in surface water. Neritic are the animals found in coastal water.
- Archaeocyte cells of sponges are totipotent cells.
- Dermal ostia of sponges are analogous to mouth, while osculum is analogous to anus.
- Hilsa is the only Indian fish that migrates from the seas to the river for breeding.

- Stone fish is the most poisonous fish.
- Bombay duck is a bony fish.
- Seabass (Diploprion) is hermaphrodite fish.
- Ampullae of Lorenzini are peculiar sense organs on their snout to note the thermal change in water.
- Electric organs of Torpedo are modified muscles. These produce an electric current of 50-60 volts.
- All the cartilaginous fishes are marine, while bony fishes are either marine or fresh-water.
- Pectoral fins of fishes act as balancers, pelvic fins as brakes and caudal fin as steering organ in locomotion.
- Echeneis (Sucker fish or Remora): Dorsal fin is modified into sucker. It shows commensalism with sharks, whale, etc. as is attached on their ventral side by its sucker for dispersal.
- Latimeria (Coelacanth): A lobe-finned bony fish and is about 70 million years old. First reported by Miss Latimer. Called living fossil.
- Golden dart poison frog from South America is the most poisonous frog. One adult frog contains enough poison to kill 2200 people.
- ∠ Largest amphibians. Japanese Giant Salamander which
 grows to a length of 1.6 m. Smallest amphibian. One of the
 South American arrow poison frogs, which measures upto 1.3
 cm.
- Amphiuma (Congo-eel) Has largest sized RBCs (75 μ m). It has gill slits but no gills, called derotremetons condition.
- Rhacophorus (Flying frog) Glides on the support of webs. Also has adhesive discs on digits.
- Hyla (Tree frog) Climbs up the tree with adhesive discs on the tips of digits. Skin is with hygroscopic glands.
- Salamandra (Spotted Salamander) Viviparous amphibian.
- The king cobra of India is the only snake in the world that builds a nest.

- Most poisonous snake-king cobra.
- Fangs of poisonous snake are maxillary teeth.
- ∠ Largest snake-python/Anaconda, may grow upto 10 meter in length.
- Seymouria It was one such ancestral reptile which probably started laying eggs on land in the permian period. It was a lizard like sluggish creature. It was a "connecting link" between amphibian and reptiles.
- Anguis (European glass snake-limbless-lizzard), chameleon pumilus, russelli (the Russell's viper), Hydrophis (sea snake)-All are viviparous.
- ✓ T.H. Huxley said "birds are glorified reptiles". The feathers are highly modified reptilian scales. Birds have scales on their legs. Their eggs resemble reptilian eggs in general but have a calcareous shell.
- Humming bird is the only bird which can fly backward as well as forward.
- Kiwi lays the largest egg in proportion to its own size.
- Vision and hearing are the most highly developed senses in a bird.
- Keoladeo Ghana National Park, Bharatpur, Rajasthan and Chilka lake Bird sanctuary Balagaon, Orissa are famous of birds.
- The Indian one horned Rhinoceros is the second largest land animal in India.
- Walrus Marine carnivore. Its tusks are upper canines and are used for digging to locate molluscs.
- Koala Bear lives without water on Eucalyptus leaves. The water in the leaves meets its requirement of water.
- Kangaroo rat never drinks water in its entire life.
- Giant panda is one of the rarest animals in the world. Pandas rarely breed in captivity. Giant pandas live only in high mountains of China.

Ordinary Thinking

Objective Questions

Important terms and classification of animals

Larva is found in

[Odisha JEE 2008]

- (a) Vertebrates
- (b) Invertebrates
- (c) Both (a) and (b)
- (d) None of these
- 2. Poikilotherms are also known as
 - [Odisha JEE 2008]
 - (a) Isotherm
- (b) Ectotherm
- (c) Endotherm
- (d) Heterotherm
- Animals/organisms floating on the surface of water are
 - [CBSE PMT 1998; BHU 1998, 2001]
 - (a) Plankton
- (b) Pelagic
- (c) Benthon
- (d) Neritic
- The body of the animal can be divided into identical halves in only one plane is [J & K CET 2010]
 - (a) Asymmetry
- (b) Bilateral symmetry
- (c) Radial symmetry
- (d) Biradial symmetry
- 5. Radial symmetry occurs in

[HPMT 1995; Chd. CET 2003; MP PMT 2006]

- (a) Fishes
- (b) Molluscs
- (c) Star Fishes
- (d) Sponges
- The space between body wall and alementary canal lined by mesoderm is called [J & K CET 2010]
 - (a) Acoelom
- (b) Pseudocoelom
- (d) None of these
- 7. In coelomates, the problem of diffusion of food from gut to tissues is solved by [EAMCET 2009]
 - (a) The presence of coelomic fluid
 - (b) Churning the food within the body cavity
 - (c) Developing a circulatory system
 - (d) Developing gut associated glands
- Trochophore larva occurs in [BHU 1995; Odisha JEE 2005] 8
 - (a) Annelida and Porifera
 - (b) Coelenterata and Annelida
 - (c) Mollusca and Coelenterata
 - (d) Annelida and Mollusca
- An animal which comes out at night and hides during day time is [CPMT 1998]
 - (a) Diurnal
- (b) Nocturnal
- (c) Cursorial
- (d) Arboreal
- Parasites capable of living without a host are called 10.

[Odisha JEE 2005]

- (a) Facultative
- (b) Permanent
- (c) Obligate
- (d) None of these
- Enterocoelous coelom is found in (a) Deuterostomia
 - [Odisha JEE 2005]
- (b) Astomia
- (c) Protostomia
- (d) Blastostomia
- 12. Non-chordates have
- [BCECE 2005]
- (a) Notocord
- (b) Dorsal tubular nerve chord
- (c) Pharyngeal gills cleft
- (d) Absence of hepatic portal system

Cell aggregate plan is found in

[AFMC 1997]

- (a) Cnidarians
- (b) Sponges
- (c) Roundworms
- (d) Flatworms
- Which of the following statements is false [Kerala CET 2005]
 - (a) Male roundworm is smaller than female
 - (b) Earthworms are hermaphrodite
 - (c) Echinoderms are protostomous coelomates
 - (d) Human teeth are anatomically comparable to scales of
 - (e) Hair is derivative of skin
- Which of the following phylum are included in enterozoa 15.

[RPMT 2001]

- (a) Annelida, Mollusca, Porifera
- (b) Echinodermata, Hemichordata, Porifera
- (c) Mollusca, Arthropoda, Hemichordata
- (d) Porifera, Mollusca, Arthropoda
- Tube-within-a-Tube body plan is shown by 16
 - (a) Coelenterates
 - (b) Platyhelminthes
 - (c) Aschelminthes (Nemethelminthes)
 - (d) Porifers
- Cold-blooded animals fall under the category of

[DUMET 2010]

(a) Ectotherms

18.

- (b) Psychrotherms (d) Thermophiles
- (c) Endotherms Blind sac body plan is shown by
- (a) Roundworms (c) Coelenterates
- (b) Annelids (d) Arthropods
- What is characteristic of deuterostomes
 - [DPMT 2001]
 - (a) Spiral cleavage, blastopore becoming mouth
 - (b) Radial cleavage, blastopore becoming anus
 - (c) Spiral cleavage, blastopore becoming anus
 - (d) Radial cleavage, blastopore becoming mouth
- 20. Mouth develops first in the embryo and anus is formed later [BHU 2012]
 - (a) Deuterostomes
- (b) Protostomes
- (c) Echinoderms
- (d) Chordates
- Which of these statements are incorrect
 - Parapodia are lateral appendages in arthropods used for swimming
 - (ii) Radula in molluscs are structures involved in excretion
 - (iii) Aschelminthes are dioecious
 - (iv) Enchinoderm adults show radial symmetry
 - (v) Ctenophorans are diploblastic
 - [Kerala PMT 2011]
 - (a) (i) and (ii)
- (b) (i) and (iii)
- (c) (i), (iv) and (v) (e) (ii), (iii) and (iv)
 - (d) (iii) and (v)
- In which triploblastic animal coelom is absent 22.

[WB JEE 2008, 11]

- (a) Platyhelminthes
- (b) Aschelminthes
- (c) Annelida
- (d) Arthropoda
- On the basis of organisation, animals are grouped into
 - [MP PMT 1997] (a) Metazoa and Eumetazoa (b) Protozoa and Metazoa
 - (c) Protozoa and Parazoa (d) Parazoa and Metazoa

(c) Climbing character

(d) Flying character

24.	Radial symmetry occurs in	36.	In contrast to annelids the Platyhelminthes show [NCERT; CBSE PMT 2005]
	[Chd. CET 1997; AFMC 2000; Kerala CET 2007]		
	(a) Porifera and Coelenterata		
	(b) Coelenterata and Echinodermata	27	(c) Bilateral symmetry (d) Absence of body cavity Animal with pseudocoelom is
	(c) Coelenterata and Platyhelminthes	37.	[RPMT 2000; DPMT 2001; Kerala PMT 2006]
	(d) Arthropoda and Mollusca		(a) Amia/Leech (b) Lepisma/Liver Fluke
5.	Coelom produced by splitting of mesoderm is [CPMT 1997]		(c) Dragon Fly/Jelly Fish (d) Wuchereria/Hookworm
	(a) Hydrocoel (b) Enterocoel	38.	Pseudocoelom develops from
	(c) Schizocoel (d) None of the above	50.	[CBSE PMT 1994; CPMT 2002; RPMT 2005]
26.	Which one of the following does not have larvae in its life		(a) Blastopore lip (b) Archenteron
	cycle [Pb. PMT 1997]		(c) Embryonic mesoderm (d) Blastocoel
	(a) Prawn (b) Earthworm	39.	A true coelom is absent in phylum
	(c) Crab (d) Cockroach		Or
27.	Coelom is cavity between alimentary canal and body wall		Which of the following is pseudocoelomate[Odisha JEE 2009]
	enclosed by [CBSE PMT 1996; JIPMER 1997;		(a) Nematoda (b) Annelida
	JKCMEE 2002; J & K CET 2005]		(c) Echinodermata (d) Mollusca
	(a) Ectoderm and endoderm (b) Mesoderm and ectoderm	40.	True coelom or body cavity occurs in [NCERT]
	(c) Ectoderm on both sides (d) Mesoderm on both sides		(a) Hydra (b) Taenia
28.	Tiny free living animals on the surface of water constitute		(c) Pheretima (d) Sycon
	[KCET 1999]	41.	Veliger larva occurs in phylum [DPMT 2001]
	(a) Zooplankton (b) Phytoplankton		(a) Mollusca (b) Echinodermata
	(c) Benthon (d) Symbionts		(c) Arthropoda (d) Cnidaria
29.	From the following statements select the wrong one	42.	Cell-tissue organisation occurs in [CBSE PMT 2000]
	[CBSE PMT 2005]		(a) Liver fluke (b) Sponge
	(a) Millipedes have two pairs of appendages in each		(c) Hydra (d) Starfish
	segment of the body	43.	A list of animals is given below. Identify the animals with
	(b) Prawn has two paris of antennae		open circulatory system and choose the correct answer.
	(c) Animals belonging to phylum porifera are exclusively		(A) Ascidia (B) Cockroach
	marine		(C) Earthworm (D) Prawn
	(d) Nematocysts are characteristic of the phylum cnidaria		(E) Silverfish (F) Snail
30.	An enterocoelomate invertebrate group is [APMEE 1999]		(G) Squid
,	(a) Annelida (b) Echinodermata		[Kerala CET 2002, 05; AMU (Med.) 2005] (a) B, D, F (b) A, B, D, F
	The second section of the second seco		(a) B, D, F (b) C, D, E, G (c) C, D, E, G (d) B, D, E, F
	(c) Arthropoda (d) Mollusca		(e) A, B, D, F, G
31.	Schizocoelomates and enterocoelomates are [AFMC 2006]	44.	Besides Annelida and Arthropoda metamerism is found in
	(a) Acoelomates (b) True coelomates	-1-1.	[NCERT; CBSE PMT 1995]
	(c) Invertebrates (d) Echinoderms only		(a) Cestoda (b) Acanthocephala
32.	Metameric segmentation is the characteristic of [NCERT;		(c) Chordata (d) Mollusca
	[HPMT 1993; CBSE PMT 2006]	45.	Organisms attached to substratum generally possesses
	(a) Annelida and Arthropoda	10.	[CBSE PMT 1995; AIIMS 1999]
	(b) Mollusca and chordata		(a) Asymmetrical body
	(c) Platyhelminthes and Arthropoda		(b) Radial symmetry
	(d) Echinodermata and Annelida		(c) One single opening of digestive canal
22			(d) Cilia on the surface to create water current
33.	A radially symmetrical diploblastic animal is [AFMC 1993]	-	
	(a) Roundworm (b) Earthworm	MICHO	Phylum-Porifera
	(c) Hydra (d) Liver Fluke	1.	Which one of the following categories of animals, is correctly
34.	Radial symmetry is often exhibited by animals having	4.	described with no single exception in it
	[CBSE PMT 1994, 96, 97]		[NCERT; CBSE PMT (Mains) 2012]
	(a) One opening of alimentary canal		(a) All reptiles possess scales, have a three chambered
	(b) Aquatic mode of living		heart and are cold blooded (poikilothermal)
	(c) Benthos/sedentary nature		(b) All bony fishes have four pairs of gills and an operculum
	(d) Ciliary mode of feeding		on each side
35.			
JJ.			(c) All sponges are marine and have collared cells (d) All mammals are viviparous and possess diaphragm for
	(a) Jumping character (b) Burrowing character		hreathing
			COPPORTED IN

breathing

2.	lissues are absent in the b	ody of [CPMT 2009]	17.	 Members of phylum per 	orifera are	
	(a) Sponge	(b) Annelida		[CBSE PM	IT 2000; AFMC 2	000; MH CET 2003
	(c) Platyhelminthes	(d) Arthropoda		(a) Exclusively marine		
3.	Which is not correct for sp	ponges [Odisha JEE 2009]		(b) Exclusively fresh v	vater animal	
	(a) Internal fertilization			(c) Mostly fresh water	animals but few	are marine animals
	(b) External fertilization			(d) Mostly marine ani	mals but few are	fresh water animals
	(c) Gemmule formation		18.			
	(d) Gametes are formed	from epidermal cells		(a) Cliona	(b) Spon	
4.	Ostia is present in	[Odisha JEE 2011]		(c) Sycon	(d) Hyale	T
	(a) Poriferans	(b) Coelenterates	19.	What is found in a spo		
	(c) Annelids	(d) Molluscs				MT 1996, 2002, 10
5.	In porifera, skeleton formi			(a) Choanocytes	(b) Nema	
		[MP PMT 2000; Odisha JEE 2012]		(c) Amoebocytes		(a) and (c)
	(a) Sclerocytes	(b) Archaeocytes	20.	Which of the following	is boring sponge	[CPMT 1999
	(c) Thesocytes	(d) Amoebocytes		Or		
6.	Glass Rope sponge is	[BVP 2000]		A sponge harmful to ou	ster industry is	[AFMC 1997]
	(a) Hyalonema	(b) Euplectella		(a) Cliona	(b) Chali	
	(c) Scypha	(d) Spongilla		(c) Euplectella	(d) Hyalo	
7.	Sponges structure corresp is	oonding to mouth of other animals [BHU 1999]	21.	Identify the names of option	the following fig	gure from the giver [NCERT]
	(a) Incurrent canal	(b) Ostium				
	(c) Osculum	(d) Excurrent canal		模型/图		apalla a
8.	The most distinctive chara	acter of sponge is [EAMCET 1998]				AND WED A
	(a) Presence of choanocy				h	P LA CO
	(c) Marine	(d) Asexual reproduction		The state of the s		
9.	Canal system is a characte			B B		C
		96; CBSE PMT 1999; RPMT 1999;		A		
		BHU 2000, 02; Odisha JEE 2011]		A	В	С
	(a) Hydra	(b) Sponge		(a) Euspongia	Sycon	Spongilla
	(c) Sea anemone	(d) Sea urchin		(b) Spongilla	Sycon	Eusporangia
10.		[CBSE PMT 1995; MP PMT 2002]		(c) Euspongia	Spongilla	Sycon
	(a) Spongilla			(d) Sycon	Euspongia	Spongilla
	(c) Leucosolenia		22.	Classification of Phylum	Porifera is based	lon
11.		of cell, internal cavities lined with			[CBSE PMT 19	991; WB JEE 2012]
		ells and indirect development are		(a) Nutrition	(b) Spicul	es
	the characteristics of phylu	ens and maneet development are		(c) Locomotion	(d) Repro	duction
	(a) Porifera		23.	Amphiblastula is the lar	va of	
	(c) Protozoa	(b) Mollusca		[AF	MC 2001; CPMT	2002; RPMT 2005]
10		(d) Coelenterate		(a) Hydra	(b) Sycon	
12.	In Leucosolenia, digestion			(c) Planaria	(d) Leuco	solenia
	(a) Paragastric cavity	(b) Stomach	24.	What is left, when baths	ponges dries up	[AIIMS 2002]
2727	(c) Osculum	(d) Food vacuole		(a) Spicules	(b) Holdfa	ast
13.	Parenchymula (sponges fre	ee swimming larva) is the larva of		(c) Tentacles	(d) Spong	in fibres
		[EAMCET 1998; CPMT 2000]	25.	What will happen if a s		
	(a) Hydra	(b) Ascaris		pieces		[RPMT 2001]
	(c) Pheretima	(d) Leucosolenia		(a) These will die		
14.	Sponges are	[BVP 2003]		(b) These will differenti	ate	
	(a) Sessile	(b) Planktonic		(c) Every piece will for	n a sponge	
	(c) Free-swimming	(d) Pelagic		(d) Some pieces will de		
15.	Which sponge is given as a		26.	Which of the following		able giving rise to
	(a) Hyalonema	(b) Euplectella	- A 100 B	other cell type in sponge		3.71113 1130 10
	(c) Tethya					02; Pb. PMT 2004]
6.		(d) Leucosolenia			Or	
		enia are produced by 1999; DPMT 1999; HPMT 2002]		Reproductive cells of spo	onges are formed	from [CBSE PMT 1991]
	(a) Choanocytes	(b) Pinacocytes		(a) Archaeocytes	(b) Collen	ocytes
	(c) Archaeocytes	(d) Thesocytes		(c) Thesocytes	(d) Pinaco	cytes

UNIVER BOOK D	234 Animal Kingdom		
27.	Spongin fibres are secreted by [BVP 2000]	38.	
	(a) Choanocytes (b) Pinacocytes		(a) Hydra (b) Planaria
	(c) Amoebocytes (d) Spongioblasts		(c) Sycon (d) Obelia
28.	The middle layer in body wall of porifera is [AIIMS 1999]	39.	Sponges are porifers because their bodies have [CPMT 1994; RPMT 200.
	Or a mendantible of		(a) Spicules in skeleton (b) Several pores
	The non-cellular layer present between pinacoderm and		(c) Canal system (d) All the above
	choanoderm in body wall of poriferans is known as	40.	
	[Odisha JEE 2012]	40.	(a) Nematodes (b) Mosquitoes
	(a) Mesoderm (b) Mesenchyme		(c) Sponges (d) Coelenterates
20	(c) Mesogloea (d) Mesentery	41.	
29.	Sponges capture food particles with the help up [BVP 2001; MHCET 2002; RPMT 2005]		(a) Red Sea (b) Gulf Mexico
	Or		(c) Pacific Islands (d) Mediterranean sea
	Feeding in sponges takes place through	42.	
	[BHU 1999; CPMT 1999, 2005]		[CBSE PMT 199
	(a) Choanocytes (b) Pinacocytes		Or Or
	(c) Thesocytes (d) Trophocytes		Type of spongocoel found in Leucosolenia is [CPMT 200
30.	Which of the following features is universally present in all		(a) Ascon type (b) Leucon type
	sponges [MP PMT 2013]		(c) Sycon type (d) Radial type
	(a) Marine habitat (b) Presence of spicules	43.	Thesocytes serve as [CPMT 199
	(c) Presence of spongin fibres (d) Presence of spongiocoel		(a) Sex cells (b) Slime secreting cells
31.	Spicules of silica occur in [APMEE 2001]		(c) Food reserve (d) Embryonic cells
	(a) Hyalonema (b) Sycon	44.	Animals devoid of respiratory, excretory and circulato
	(c) Leucosolenia (d) Grantia		organs are [HPMT 1993; DPMT 2002, 0
32.	In most simple type of canal system of porifera, water flows		(a) Tapeworms (b) Sponges(Porifera)
	through which one of the following ways		(c) Thread worms (d) Liver Fluke
	[NCERT; WB JEE 2012]	45.	
	(a) Ostia → Spongocoel → Osculum → Exterior		(a) Sponges (b) Hydra
	(b) Spongocoel → Ostia → Osculum → Exterior		(c) Sandworm (d) Star fish
	(c) Osculum → Spongocoel → Ostia → Exterior	46.	
	(d) Osculum → Ostia → Spongocoel → Exterior		(a) Extracellular
33.	One of the following is not a characteristic feature of		(b) Intracellular
	sponges [NCERT; Kerala PMT 2010]		(c) First extracellular and then intracellular
	(a) Cellular level of organization	455	(d) First intracellular and then extracellular
	(b) Presence of ostia	47.	Carmine particle put above osculum of a sponge would be [CPMT 199]
	(c) Intracellular digestion		(a) Left there
	(d) Body supported by chitin		(b) Ingested and digested
	(e) Indirect development		(c) Thrown away
34.	Internal asexual propagule of some fresh water sponges is		(d) Ingested and thrown away by ostia
J4.	[Kerala PMT 2006]	48.	
	Or	10.	(a) Respiration (b) Nutrition
	Internal bud for overcoming unfavourable conditions in		(c) Sexual reproduction (d) None of these
	Leucosolenia is [CPMT 1996]	49.	
	(a) Gemmule (b) Planula		[AFMC 1997; BVP 2004
	(c) Stereoblastula (d) Amphiblastula		(a) Sponges (b) Coelenterates
35.	Skeleton made of spongin fibres occurs in		(c) Prokaryotes (d) Vertebrates
JJ.	[CPMT 2001; RPMT 2001]	50.	Sponges have evolved from [RPMT 199
	(a) Calcarea (b) Demospongiae		(a) Ciliates (b) Flagellates
	(c) Hexactinellida (d) Both (a) and (b)		(c) Protozoans (d) Choanoflagellates
26	Digestion of food occurs in sponges Leucosolenia in	51.	Which is universal for sponges [CBSE PMT 199
36.	Digestion of 1000 occurs in sponges Leucosolenia in		(a) Marina (b) Calcaragus spigulas

(a) Spongocoel

(c) Amoebocytes

(d) Choanocytes

(c) Echinodermata

(a) Porifera

(b) Choanocytes followed by amoebocytes

(b) Coelenterata

(d) Mollusca

37. Venus Flower Basket belongs to Phylum

(d) Choanoflagellates [CBSE PMT 1996] onges (b) Calcareous spicules (c) Radial symmetry (d) High regenerative power 52. In sponges, canal system develops due to [CBSE PMT 1996] (a) Gastrovascular system (b) Folding of inner walls (c) Porous walls (d) Reproduction 53. Osculum occurs in [BHU 1997] (b) Ray Fish (a) Star Fish (c) Hydra (d) Sponge

[CPMT 1998]

[MP PMT 1994]

Incurrent canals are lined by

ICPMT 19981

- (a) Choanocytes
- (b) Pinacocytes
- (c) Porocytes
- (d) None of the above
- 55.
- Choanocytes in Ascon-type of canal system form lining of [NCERT; CPMT 1998]
 - (a) Spongocoel
- (b) Porocyte
- (c) Apopyle
- (d) Incurrent canal
- 56. In case of poriferans, the spongocoel is lined with flagellated cells called [NEET 2017]
 - (a) Ostia
- (b) Oscula
- (c) Choanocytes
- (d) Mesenchymal cells

Phylum-Coelenterata

- Larva of jelly fish (Aurelia)
- [Odisha JEE 2008]
- (a) Planula
- (b) Polyp
- (c) Medusa

3.

- (d) Blastula
- 2. Highest degree of polymorphism is found in

[J & K CET 2008]

- (a) Protozoa
- (b) Cnidaria
- (c) Platyhelminthes
- (d) Arthropoda
- The dioecious animal is
- [J & K CET 2008]
- (a) Liverfluke
- (b) Aurelia (d) Earthworm
- (c) Tapeworm Metagenesis referes to

- [AIPMT 2015]
- (a) Alternation of generation between asexual and sexual phases of an organisms
- (b) Occurrence of a drastic change in form during post embryonic development
- (c) Presence of a segmented body and parthenogenetic mode of reproduction
- (d) Presence of different morphic forms
- 5. Which of the following do not have polyp form [RPMT 1995]
 - (a) Hydrozoa
- (b) Scyphozoa
- (c) Anthozoa
- (d) All the above
- 6. Which shows polymorphism

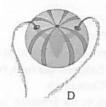

[CPMT 1998; MP PMT 2009; BHU 2012]

- (a) Physalia
- (b) Trypanosoma
- (c) Termite
- (d) All of the above
- 7. Select the right option in which all the following figures are correctly identified [NCERT]

	A	В	С	D
(a)	Adamsia	Aurelia	Pleurobrachia	Cnidoblast
(b)	Cnidoblast	Pleurobrachia	Adamsia	Aurelia
(c)	Aurelia	Adamsia	Cnidoblast	Pleurobrachia
(d)	Pleurobrachia	Cnidoblast	Aurelia	Adamsia

8. Most appropriate term to designate the life cycle of Obelia is

[NCERT; BHU 2002]

- (a) Neoteny
- (b) Metagenesis
- (c) Metamorphosis
- (d) None of these
- Which of the following does not belong to phylum Coelenterata [MP PMT 2002]
 - (a) Sea pen
- (b) Sea feather
- (c) Sea cucumber
- (d) Sea fan
- Sea anemone belongs to class
- (a) Hydrozoa
- (b) Anthozoa
- (c) Scyphozoa
- (d) None of these
- Primitive nervous system is formed in
 - [CPMT 2009]
- (a) Sponge

11.

- (b) Cnidaria (Coelenterata)
- (c) Echinodermata
- (d) Annelida
- Corals belong to the phylum
- (a) Protozoa
- (b) Porifera
- (c) Cnideria
- (d) Mollusca
- 13. The phylum of comb jelly is
- [NCERT; RPMT 1999]
- Or

Which one of the following groups of animals reproduces only by sexual means [NEET (Karnataka) 2013]

- (a) Mollusca
- (b) Echinodermata
- (c) Coelenterata
- (d) Ctenophora
- 14. Hydra is
- [RPMT 1999, 2002] (b) More developed
- (a) Herbivorous (c) Carnivorous
- (d) Omnivorous
- 15. Polyp phase is absent in
 - (a) Hydra
- (b) Aurelia
- (c) Physalia
- (d) Obelia
- 16. Jelly fish is placed in which class of coelenterata
 - [RPMT 1995]

[BHU 2006]

- (a) Anthozoa
- (b) Scyphozoa
- (c) Hydrozoa
- (d) None of the above
- One of the special characters of coelenterata only is the occurrence of [CBSE PMT 1994; CPMT 1999; BHU 1999; MP PMT 2002, 06]
 - (a) Hermaphroditism
- (b) Flame cells

(d) Nematocysts

- (c) Polymorphism
- Organ pipe coral is (a) Astrea

18.

- (b) Tubipora
- (c) Fungia
- (d) Meandrina
- Nematoblast of Hydra are
- (a) Sensoru
- (b) Complicated
- (c) With nematocyst apparatus
- (d) All of the above
- 20. The nitrogeneous metabolic waste in Hydra mostly

[AFMC 2006]

[RPMT 2006]

- (a) Ammonia and is removed from whole surface of body
- (b) Urea and is removed mainly by tentacles
- (c) Urea and is removed from whole surface of body
- (d) Uric acid and is removed from whole surface of body

BUUNEL			
21.	A mature Hydra usually bears [CPMT 2002; RPMT 2005]	34.	In which class of coelenterata the polyp and medusa both are found in one animal [RPMT 2001
	(a) One testis and several ovaries		are round in one sinner
	(b) One testis and one ovary		
	(c) Several testes and one ovary		(c) Anthozoa (d) None of them
00	(d) Several testes and several ovaries Main cavity in the body of <i>Hydra</i> is called [CPMT 1998]	35.	Which of the following belongs to anthozoa [CPMT 1999
22.	Train carry in me only or y		(a) Aurelia (b) Fungia
			(c) Stercularia (d) Dugesia
0.0	(c) Haemocoel (d) Pseudocoelom Pneumatophore helps in [RPMT 1999]	36.	Match the following and choose the correct option
23.	(a) Feeding (b) Reproduction		i. Physalia A. Sea anemone
	(c) Protection (d) Floating		ii. Meandrina B. Brain coral
24.	Which of the following statements is incorrect [CPMT 2010]		iii. Gorgonia C. Sea fan
27.	(a) Cnidocil is for defence in Hydra		iv. Adamsia D. Portuguese man of war
	(b) Nerve cells are absent in Hydra		[Bihar MDAT 1995; Kerala PMT 2002,12
	(c) Hydra is a coelentrate		(a) i-C; ii-B; iii-A; iv-D (b) i-D; ii-C; iii-B; iv-A
	(d) Hydra shows budding		(c) i-D; ii-B; iii-C; iv-A (d) i-B; ii-C; iii-A; iv-D
25.	A coral island with a central shallow lake is known as		(e) i-A; ii-B; iii-C; iv-D
	[BHU 2001]	37.	Statocysts are sense organs of [CPMT 1999
	(a) Coral reef (b) Atoll		(a) Ascaris (b) Paramecium
	(c) Corallite (d) Diatomaceous sheath		(c) Taenia solium (d) Obelia medusa
26.	Why does the Ctenophora is a minor phylum [RPMT 2001]	38.	
	(a) It includes small sized animals	56.	(a) Frog (b) Obelia
	(b) It includes only few genera		
	(c) It does not include animals of economic importance		
	(d) It was included earlier in cnidaria	39.	
27.	The larva of hydra is [RPMT 1999]		(u) Thatha symmeny
	(a) Planula (b) Rhabditoid		(b) Coelomates – Aschelminthes
	(c) Trochophore (d) None of these		(c) Metamerism – Molluscs
28.	The true statement regarding corals is [AIIMS 1999]		(d) Triploblastic – Sponges
	(a) They form branched colonies		(e) Metagenesis – Echinoderms
	(b) Are solitary or colonial polypoid(c) They grow as massive bodies	40.	
	(d) All of these		[CPMT 2000; BHU 2000
29.	Hydra is [CPMT 1993; RPMT 1999, 2000;		(a) Planula (b) Cysticercus
27.	Pb. PMT 2000; Odisha JEE 2012]		(c) Rhabdiform (d) Wriggler
	occupation or	41.	Among the following organisms point out a completely nor parasitic form [CBSE PMT 1994]
	Coelenterates generally include animals which are		(a) Sea anemone (b) Leech
	[CMC Vellore 1993]		
	(a) Triploblastic, radial symmetry and accelomate	40	
	(b) Triploblastic, radial symmetry and coelomate	42.	. Which of the following is not found in vertebrates [MP PMT 1998]
	(c) Diploblastic, radial symmetry and acoelomate		(a) Bilateral symmetry (b) Gill opening
	(d) Diploblastic, radial symmetry and coelomate		(c) Body scales (d) Cnidoblasts
30.	Symmetry in Cnidaria is [CBSE PMT 2005]	12	
	(a) Radial (b) Bilateral	43.	[RPMT 200
	(c) Pentamerous (d) Spherical		(a) Porifera (b) Coelenterata
31.	How many ova are formed in the ovary of hydra		(c) Platyhelminthes (d) Nemathelminthes
	[RPMT 1999]	44.	
	(a) 2 (b) 4	72.2	(a) Epithelio-muscular cells (b) Cnidocyte
	(c) 1 (d) 3		(c) Choanocyte (d) Nerve cells
32.	Which one of the following animals is a coelenterate	45.	
	[MP PMT 2003; CPMT 2005]	40.	brain [CBSE PMT 1993, 2002; BVP 200
	(a) Sea cow (b) Sea horse		(a) Pheretima (b) Hydra
200	(c) Sea cucumber (d) Sea pen		(c) Amoeba (d) Periplaneta
33.	Hydra receives impulses and stimuli through	46.	
	[CBSE PMT 2000; AIIMS 2002]		(a) Nematocysts of Hydra (b) Tentacles of Hydra
	(a) Nerve net (b) Sensory cells		(c) Zooids of Obelia (d) Tentacles of Obelia
	(c) Nematocytes (d) All of these		1-1

Animal Kingdom 237 UNIVERSAL BOOK DEPOT 1968

47.	Tentacles of <i>Hydra</i> appear to be [Odisha JEE 2012]	61.	
	(a) 2 (b) 15 (c) 8 (d) 14		(a) Water (b) Touch
48.	The gastrovascular cavity of <i>Hydra</i> provides for		(c) Brain (d) None of the above
40.	(a) Digestion and storage (b) Storage and circulation	62.	Which one of the following living organisms completely lacks a cell wall [CBSE PMT 2014]
49.	(c) Excretion and storage (d) Digestion and circulation Testes are located in <i>Hydra</i> at		(a) Saccharomyces (b) Blue – green algae
77.	(a) Proximal half (b) Distal half		(c) Cyanobacteria (d) Sea – fan (Gorgonia)
	(c) Middle (d) Tentacles	63.	Which pair of cells is present in epidermis of Hydra but no
50.	Zoochlorellae and zooxanthallae present in Hydra are		in its endoderm [Bihar MDAT 1995]
	[CPMT 1994; RPMT 1996]		(a) Stinging cells and interstitial cells
	(a) Symbionts in nutritive cells		(b) Gland cells and germ cells
	(b) Symbionts in the gut		(c) Stinging cells and germ cells
	(c) Symbionts in cnidoblasts		(d) Stinging cells and gland cells
	(d) Organisms that provide hypnotoxin	64.	If Hydra is broken into pieces [RPMT 1995, 96; CPMT 1996]
51.	Body cavity of Hydra is called		(a) Hydra will die
	[JIPMER 1998; Odisha JEE 2012]		(b) Every fragment will grow into complete Hydra
	(a) Enterocoel (b) Coelenteron		(c) Some fragments will form complete
	(c) Gastrovascular cavity (d) Both (b) and (c)		(d) Hydra will undergo sexual reproduction
52.	Precious Red Coral is/Coral used in ornaments is	65.	Testes/gonads are formed in <i>Hydra</i> from
	[MP PMT 1993]		[RPMT 1995; Bihar MDAT 2001]
	(a) Astraea (b) Fungia (c) Corallium (d) Tubipora		(a) Interstitial cells (b) Epithelio-muscular cells
53.	(c) Corallium (d) Tubipora Gonads of Obelia occur		(c) Nerve cells (d) All the above
JJ.	(a) In hydrula stage and indefinite in number	66.	
	(b) Bases of tentacles of medusa and 8 in number	00.	Food of Hydra is [RPMT 1995] (a) Aquatic plants
	(c) On blastostyles and 8 in number		
	(d) On radial canals, oral surface of medusa and four in		(b) Aquatic animals
	number		(c) Algae and aquatic animals
54.	Gastrodermis of Hydra takes part in digestion of		(d) Some crustaceans
	(a) Carbohydrates and fats	67.	A number of buds have developed on Hydra
	(b) Proteins and fats		[APMEE 1996; Pb. PMT 1999]
	(c) Proteins, fats and some carbohydrates		(a) Oldest bud is towards oral region
	(d) Proteins and carbohydrates		(b) Oldest bud is towards aboral region
55.	The cells absent in gastrodermis of Hydra are		(c) Both (a) and (b)
	(a) Nutritive cells (b) Stinging cells		(d) There is no order
	(c) Gland cells (d) Nerve cells	68.	Mesogloea of Hydra is made of [RPMT 1996]
56.	Muscles of Hydra are		(a) Mucopolysaccharides (b) Protein
	(a) Smooth (b) Skeletal		(c) Protein and fat (d) Reticulate tissue
	(c) Both (a) and (b) (d) None of the above	69.	Characteristic feature of coelenterata is [CPMT 1996]
57.	Budding is a normal mode of asexual reproduction in		(a) All are marine
	[CBSE PMT 1993; CPMT 1996; HP PMT 2005;		(b) Presence of tentacles around mouth
	Kerala PMT 2009; Odisha JEE 2009, 10]		(c) Polyp
	(a) Starfish and Hydra (b) Hydra and sponges		(d) Gastrovascular cavity
.0	(c) Tapeworm and Hydra (d) Sponges and starfish	70.	Which of the following during respiration obtain water
58.	Which of the following is not present in the body wall of Hydra [CPMT 2010]		dissolved oxygen by diffusion through their body surface [HP PMT 2005]
	(a) Sensory cell (b) Glial cell		(a) Cnidarians (b) Fishes
.0	(c) Cnidoblasts (d) Nerve cell		(c) Amphibians (d) Reptiles
59.	Nematocysts take part in [MP PMT 1993]	71.	Hydra recognises its prey by [BVP 2001; MHCET 2003]
	(a) Locomotion (b) Offence and defence		(a) Nematocyst (b) Chemical stimulus
	(c) Food capture (d) All the above		(c) Smell (d) Sensitivity
50.	Which is wrongly matched [Odisha JEE 2004]	72.	Common name of Fungia is [Bihar MDAT 1996]
	(a) Euglinoidae → Myonemes (b) Ciliophora → Axonemes		(a) Mushroom Coral (b) Red Coral
	(c) Annelida → Notopodia (d) Cnidaria → Parapodia		(c) Brain Coral (d) Organ Pipe Coral

238 Animal Kingdom 73. In Hydra new nematocysts develop from [BHU 1996] Hydra will regenerate from a fragment, if it contain (a) Cnidocils (b) Glandular cells [AFMC 2001] (c) Germ cells (a) Tentacles (d) Interstitial cells (b) Epidermis and gastrodermis Polymorphism occurs in [BHU 1997] (c) Tentacles, epidermis and gastrodermis (a) Anthozoa (b) Scyphozoa (d) Epidermis, hypodermis and gastrodermis (c) Rhizopoda (d) Hydrozoa 85. Bilateral symmetry does not occur in Medusa of Obelia is [Pb. PMT 2001] [AIIMS 1999] (b) Octopus (a) Carnivorous (b) Herbivorous (c) Mammal (d) Obelia (c) Detritus feeder Omnivorous 86. Ctenophores have similarities with members [RPMT 2002] 76. Sense organs of Aurelia are [AIIMS 1999] (a) Porifera (b) Coelenterata (a) Tentilla (b) Tentaculocyst (c) Arthropoda (d) Annelida (c) Nematocyst (d) Otolith Larva like stage of Hydra is [RPMT 2002] Germ cells of Hydra are derived from **IBHU 20001** (a) Hydrula (b) Hydratuba (a) Ectoderm (b) Endoderm (c) Scyphula (d) Planula (c) Mesoderm (d) Mesogloea 78. Looping and somersaulting types of locomotion are seen in Phylum-Platyhelminthes [Odisha JEE 2011] Solenocytes and nephridia are respectively found in (a) Leech (b) Amoeba [RPMT 2002] (c) Snail (d) Hydra (a) Platyhelminthes and Annelids 79 The figure shows four animals (A), (B), (C) and (D). Select (b) Annelids and Nematoda the correct answer with respect to a common characteristics Cnidaria and Mollusca of two of these animals (d) Mollusca and Echinodermata 2. Which of the following is a free living flat worm [NCERT; RPMT 2001; AMU (Med.) 2005] (a) Planaria (b) Taenia (c) Fasciola (d) Pheretima 3. In which of the following organisms, self fertilization is seen [KCET 2007; AFMC 2012] (a) Fish (b) Roundworm (c) Earthworm (d) Liver fluke (C) Which one of the following kinds of animals are triploblastic [AIIMS 2010; CBSE PMT (Pre.) 2010] (a) Corals (b) Flat worms (c) Sponges (d) Ctenophores Cestodes are distinguished from other flatworms by the absence of [CPMT 2001] [CBSE PMT (Mains) 2011] (a) Nervous System (b) Digestive system (a) (A) and (B) have cnidoblasts for self-defence (c) Excretory system (d) Reproductive system (b) (C) and (D) have a true coelom 6. Which one of the following is an example of platyhelminthes (c) (A) and (D) respire mainly through body wall [CBSE PMT 1994; AIIMS 1999] (d) (B) and (C) show radial symmetry (a) Trypanosoma (b) Schistosoma 80. In Hydra, cnidoblasts employed during looping are (c) Plasmodium (d) Wuchereria [APMEE 2000] 7. Fasciola hepatica is [AFMC 2008] (a) Volvents (b) Stenoteles (a) Hermaphrodite, self fertilising (c) Atrichous isorhizas (d) Desmonemes (b) Hermaphrodite, cross fertilising (c) Unisexual Animal showing thigmotaxis is **ICPMT 20001** (d) Both (a) and (b) (a) Ascaris (b) Taenia Which of the following animals does not have a body (c) Fungia (d) Hydra [Odisha JEE 2009] composed of many segments 82. Which of the following symmetry is found in adult sea-(a) Flatworm (b) Grass hopper [CPMT 2004; Odisha JEE 2009] anemone (c) Earthworm (d) Lobster (a) Biradial (b) Spherical Cysticercus is the larva of [AFMC 2001; WB JEE 2010] (d) None of these (a) Liver fluke (b) Tapeworm (Taenia) 83. Which is correct about nematocyst in Hydra [AFMC 2001] (c) Ascaris (d) Mollusca (a) It is re-used 10. Planaria, liver fluke and taenia solium are (b) Ejection is conditioned reflex [NCERT; CBSE PMT 1993] (c) Ejection occurs in response to contact and pierces the prey (a) All segmented (b) All found in the gut (d) Prevents coming in contact with other Hydra

(c) All have coelom

(d) All are flatworms

11.	All flatworms differ from	m all roundworn

[EAMCET 1998]

- (a) Acoelomates
- (b) Pseudocoelomates
- (c) Haemocoelomates
- (d) Coelomates
- Rhabdites occur in
- [AIIMS 1999; RPMT 2000]
- (a) Planaria/Dugesia
- (b) Fasciola (d) Echinococcus
- (c) Taenia 22. "Triploblastic, unsegmented, acoelomate exhibiting bilateral symmetry and reproducing both asexually and sexually with parasitic forms." The above description is characteristic of
 - phylum (a) Platyhelminthes
- (b) Annelida
- (c) Ctenophora
- (d) Cnidaria
- (e) Porifera

23. The contrast to Annelids the Platyhelminthes show

[CBSE PMT 2005]

- (a) Absence of body cavity
- (b) Bilateral symmetry
- (c) Radial symmetry
- (d) Presence of pseduocoel

[Kerala CET 2005; MP PMT 2011]

- 24. The greatest ability of regeneration amongst the animals is found in [HP PMT 2005; Kerala PMT 2010; CBSE PMT 2014]
 - (a) Ascaris
- (b) Pheretima
- (c) Hirudinia
- (d) Planaria (Dugesia)
- 25. A metozoan covered by cilia is
- [APMEE 2000]
- (a) Paramecium
- (b) Dugesia
- (c) Fasciola 26.
- (d) Ascaris
- Chloragogen cells resemble the following in function [Manipal 2005]
 - (a) Collared cells
- (b) Flame cells
- (c) Plasma cells
- (d) Mesophyll cells [DPMT 2004]
- 27. Pseudocoelom is not found in
 - (b) Ancylostoma
 - (a) Ascaris
- (c) Fasciola
- (d) None of these
- 28. One example of animals having a single opening to the outside that serves both as mouth as well as anus is [CBSE PMT (Pre.) 2010]
 - (a) Fasciola
- (b) Octopus
- (c) Asterias

- (d) Ascidia
- 29. Which of the following show anaerobic respiration [MP PMT 2006]
 - (a) Earthworms
- (b) Rabbit
- (c) Echinoderms
- (d) Tapeworms
- 30. Bilaterally symmetrical but acoelomate animal is
 - [DPMT 2003; BVP 2004]
 - (a) Liver fluke
- (b) Jelly fish
- (c) Round worms
- (d) Crab
- 31.
- Sometimes parasites themselves are parasitised by other organism, such parasites known as [AFMC 2003] (a) Symbionts
- (b) Endoparasites
- (c) Ectoparasites
- (d) Hyperparasites
- 32. Mehlis's glands of Tapeworm are associated with
 - **IBHU 20021**
 - (a) Reproduction
- (b) Excretion
- (c) Respiration
- (d) Circulation
- Malpighian tubules are analogous to

- [AFMC 2010]
- (a) Trachea of cockroach
- (b) Gills
- (c) Flame cells

- (d) None of these
- Tapeworm does not possess digestive system as it 34.
 - [BHU 1994]
 - (a) Does not require solid food
 - (b) Obtains food through general surface
 - (c) Does not require food
 - (d) Lives in intestine

- [CMC Vellore 1993]
- (a) Radially symmetrical
- (b) Externally segmented
- (c) Triploblastic
- (d) Pseudocoelomate
- The parasite found in the seminal vesicle of earthworm [RPMT 1999, 2006]
 - (a) Monocystis
- (b) Nosema
- (c) Sarcocystis
- (d) Nyctotherus
- Which one of the following is NOT a characteristic of 6. phylum Annelida
 - [DPMT 2003; BVP 2004; **CBSE PMT 2008]**
 - (a) Pseudocoelom
- (b) Ventral nerve cord
- (c) Closed circulatory system (d) Segmentation
- 7. Which one of the following is not hermaphrodite animal [HP PMT 2005; Odisha JEE 2008]
 - (a) Leeches
- (b) Polychaetes
- (c) Flatworms
- (d) Earthworm
- 8. Pheretima posthuma and Periplanata are similar in which aspect [CPMT 1995]
 - (a) Both have nephredia as excretory organs
 - (b) Both have ventral nerve cord
 - (c) Both belong to same taxonomical group
 - (d) All the above
- 9. Which of the following belongs to the phylum annelida
 - [Odisha JEE 1997]

- (a) Octopus
- (b) Ant
- (c) Nereis
- (d) Crab
- Specialized chemoreceptors located on the anterior part of 10. earthworms are [Kerala PMT 2012]
 - (a) Heat receptors
- (b) Photo receptors
- (c) Taste receptors
- (d) Pressure receptors
- (e) Auditory receptors
- Closed blood vascular system, liver cells in the blood and chitinous setae or parapodia are the characteristics of [AFMC 2009]
 - (a) Arthropoda
- (b) Nematoda
- (c) Annelida
- (d) None of these
- 12. See the figure given below and identify A to D respectively

[NCERT]

- (a) A Seminal vesicle, B Testis, C Prostate gland,
 - D Accessory gland
- (b) A Testis, B Seminal vesicle, C Prostate gland,
 - D Accessory gland
- (c) A Seminal vesicle, B Testis, C Accessory gland,
 - D Prostate gland
- (d) A Testis, B Seminal vesicle, C Accessory gland,
 - D Prostate gland

In which of the following, clitellum is absent 13.

[BHU 2000]

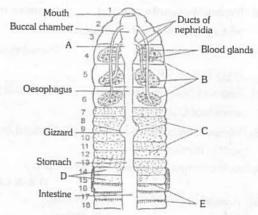

- (a) Polychaeta
- (b) Oligochaeta
- (c) Hirudinea
- (d) All the above
- One very special feature in the earthworm pheretima is that

[NCERT; AFMC 1999; CBSE PMT (Pre.) 2011]

- (a) It has a long dorsal tubular heart
- (b) Fertilisation of eggs occurs inside the body
- (c) The typhlosole greatly increases the effective absorption area of the digested food in the intestine
- (d) The S-shaped setae embedded in the integument are the defensive weapons used against the nemies
- Botryoidal tissue is found in 15.

[BHU 2002]

- (a) Rabbit
- (b) Ascaris
- (c) Hirudinaria
- (d) Earthworm
- Identify the following structures labelled A to E in the 16. diagram given below from the list I to V

- I. Septal nephridia
- II. Pharynx
- Forest of integumentary nephridia
- IV. Integumentary nephridia
- Tufts of Pharyngeal nephridia

[NCERT]

(d)	II	I	III	IV	V

- In Pheretima, there are red coloured round bodies in 4th, 5th and 6th segments above the alimentary canal. They are believed to be involved in [NCERT; BHU 1999]
 - (a) Excretion
- (b) Digestion
- (c) Reproduction
- (d) Leucocyte production
- Which one of the following exhibits concentric "tube within 18. tube" plan [MP PMT 1999]
 - (a) Arthropoda
- (b) Oligochaeta
- (c) Mollusca
- (d) Echinodermata
- 19. The colour of the body in earthworm is brown due to the presence of [CPMT 2001]
 - (a) Porphyrin
- (b) Haemoglobin
- (c) Blood
- (d) Haemocyanin

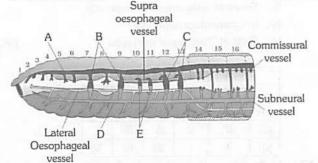

- 20. The famous Indian Zoologist who wrote a memoir upon Pheretima posthuma is [CBSE PMT 2001]
 - (a) J.C. Bose
- (b) M.L.Bhatia
- (c) K.N.Bahl
- (d) Beni Prasad
- The highly degraded organic matter rich in nitrogen and 21. potassium in particular, resulting from the activity of earthworms, is called **INCERT: KCET 20061**
 - (a) Worm castings
- (b) Vermicompost
- (c) Compost bedding
- (d) Humus
- In which of the following class of Annelida, one pair ovaries 22. and several pair testes are found [MP PMT 2003]
 - (a) Archiannelida
- (b) Hirudinea
- (c) Oligochaeta
- (d) Polychaeta
- Which one of the following pairs of items correctly belongs to the category of organs mentioned against it

[CBSE PMT 2008]

- Excretory organs (a) Nephridia of earthworm and malpighian tubules of Cockroach
- (b) Wings of honey bee and wings of crow
- Homologous organs
- (c) Thorn of Bougainvillea and
- Analogous organs
- tendrils of Cucurbita
- (d) Nictitating membrane and blind Vestigial organs spot in human eye
- Aphrodite, commonly known as sea mouse is a

[J & K CET 2008]

- (a) Annelid
- (b) Mollusca
- (c) Insect
- (d) Mammal
- Observe the blood vascular system of earthworm given in 25. INCERTI the following figure

	A	В	С	D	E
(a)	Ventral vessel	Lateral hearts	Anterior loop	Dorsal vessel	Lateral- oesopharyng eal hearts
(b)	Dorsal vessel	Lateral hearts	Anterior loop	Ventral vessel	Lateral- oesopharyng eal hearts
(c)	Ventral vessel	Lateral hearts	Lateral- oesopharyngeal hearts	Dorsal vessel	Anterior loop
(d)	Dorsal vessel	Lateral hearts	Lateral- oesopharyngeal hearts	Ventral vessel	Anterior loop

- The two organisms which breathe only through their moist [Odisha JEE 2009; J & K CET 2012]
 - (a) Fish and frog
- (b) Frog and earthworm
- (c) Leech and earthworm
- (d) Fish and earthworm
- Earthworms are 27.

- [CBSE PMT 2006]
- (a) Uricotelic under conditions of water scarcity
- (b) Ammonotelic when plenty of water is available
- (c) Ureotelic when plenty of water is available
- (d) Uricotelic when plenty of water is available
- In the 4th, 5th and 6th segments of earthworm, lying above 28. pharyngeal mass and connected with pharyngeal glands are found small, red coloured follicular bodies called

[NCERT; APMEE 2002; Kerala PMT 2006]

- (a) Septal glands
- (b) Blood glands
- (c) Salivary glands
- (d) Nephridia
- (e) Intestinal caecae
- Region of Earthworm which is forest of nephridia is 29.

[NCERT; CPMT 2002]

[RPMT 1998]

- (a) Clitellar region
- (b) Pharyngeal region
- (c) Typhlosolar region
- (d) Intestinal region
- Chloragogen cells are present in 30.

 - (a) Body wall of Leucosolenia
 - (b) Blood of Earthworm
 - (c) Coelomic fluid of Earthworm
 - (d) Blood of Cockroach
- Leech is 31.

[J & K CET 2005]

- (a) Carnivorous
- (b) Sanguivorous
- (c) Ectoparasite
- (d) Both (b) and (c)
- In Earthworm, genital papillae occur in segments [NCERT] 32.
 - (a) 16 and 17
- (b) 16 and 18
- (c) 17 and 19
- (d) 17 and 18
- Flow of blood in dorsal blood vessel of Earthworm is 33.
 - (a) Backward
- (b) Forward
- (c) Sideward
- (d) Downward
- The lateral hearts in earthworm have 34.

[NCERT; AMU (Med.) 2010]

- (a) Four pairs of valves and are situated in segments 7 and 9
- (b) Four pairs of valves and are situated in segments 6 and 8
- (c) Three pairs of valves and are situated in segments 8 and 10
- (d) Two pairs of valves and are situated in segments 6 and 11
- The female genital aperture in earthworm is present 35 ventrally on the segment [NCERT; CPMT 2000; BHU 2006]
 - (a) 10th
- (b) 12th
- (c) 14th
- (d) 18th
- In earthworm, the characteristic internal median fold of 36. dorsal wall of the intestine called typhlosole is present in

[Kerala PMT 2008]

- (a) 5 to 9 segments
- (b) 9 to 14 segments
- (c) 26 to 35 segments
- (d) 15 to last segment
- (e) 35 to last segment
- 37. Hearts of Pheretima are situated in the segments
 - (a) 10, 13, 16 and 17 (b) 7, 9, 12 and 13
 - (c) 4, 5, 10 and 13
- (d) 11, 14, 17 and 18

[NCERT]

38. In earthworm fertilization occurs in

[NCERT; CPMT 2005; Bihar CECE 2006]

[NCERT]

- (a) Oviduct
- (b) Spermatheca
- (c) Clitellum
- (d) Coccon
- (a) Coccon formation
- The main function of clitellum is[RPMT 2002; BCECE 2005]
 - (c) Excretion
- (b) Locomotion (d) Copulation
- 40. Pheretima is

39.

42.

- (a) Sterile
- (b) Hermaphrodite
- (c) Radially symmetrical
- (d) Dioecious
- In Pheretima, gizzard, buccal cavity, pharynx, oesophagus, 41. pharyngeal nephridia receive the blood from this blood [EAMCET 2009]
 - (a) Supra oesophageal
- (b) Lateral oesophageal
- (c) Dorsal Blood
- (d) Subneural Major nitrogenous excretory material of Earthworm is
- (a) Uric acid
- (b) Ammonia
- (c) Urea
- (d) Amino acids
- Occurrence of Earthworm in soil is indicated by
 - (a) Heaps of small rounded pellets
 - (b) Heaps of dry powder soil
 - (c) Holes
 - (d) Cast skin
- 44. Clitellum of Pheretima is thick girdle that is

INCERT:

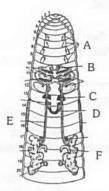

- BHU 1996; MHCET 2003; AFMC 2010] (a) Nonglandular around 14-16 segments
 - (b) Glandular around 14-16 segments
 - (c) Glandular around 16-18 segments
 - (d) Nonglandular around 16-18 segnments
- 45. The location of lymph glands in Pheretima is

[NCERT: EAMCET 2009]

- (a) 4^{th} , 5^{th} and 6^{th} segments (b) 10^{th} to 20^{th} segments
- (c) 26th to the last segments (d) 13th segment
- 46. Trochophore larva is found in

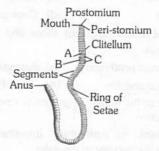

(c) Aphrodite

- [CPMT 2005]
- (a) Chiton
- (b) Nereis (d) All of these
- Choose the correct combination of labelling from the options given [NCERT; Kerala PMT 2009, 11]

- (a) A testis, B spermatheca, C seminal vesicle, D - ovary, E - vas deferens, F - accessory gland
- (b) A spermatheca, B testis, C ovary, D seminal vesicle, E - vas deferens, F - accessory gland
- (c) A spermatheca, B testis, C seminal vesicle, D - ovary, E -vas deferens, F - accessory gland
- (d) A spermatheca, B testis, C accessory gland, D - ovary, E - vas deferens, F - seminal vesicle
- (e) A spermatheca, B ovary, C seminal vesicle, D - testis, E - vas deferens, F - accessory gland

- Earthworm has
- (a) Two eyes
- (b) Many eyes
- (c) No eyes
- (d) One eyes
- Photoreceptors of Earthworm occur on
 - (a) Clitellum
- (b) Anal segment
- (c) Dorsal surface
- (d) Lateral sides
- Examine the ventral view of earthworm and identify A, B INCERTI

	A	В	С
(a)	Female genital pore	Male genital pore	Genital papilla
(b)	Female genital pore	Genital papilla	Male genital pore
(c)	Male genital pore	Female genital pore	Genital papilla
(d)	Excretory pore	Female genital pore	Male genital pore

Pheretima posthuma (earthworm) is highly useful as

[NCERT]

Or

Most important use of earthworm is

[CBSE PMT 1990; AFMC 2000]

- (a) Their burrows make the soil loose
- (b) They make the soil porous, leave their castings and take organic debris in the soil
- (c) They are used as fish meal
- (d) They kill the birds due to biomagnification of chlorinated hydrocarbons
- 52. Earthworm possesses hearts

INCERT: CBSE PMT 1991; RPMT 2000; AFMC 2006]

- (b) 4 pairs
- (a) 6 pairs (c) 2 pairs
- (d) 1
- The septal and pharyngeal nephridia open into alimentary canal and are of enteronephric type. It is an adaptation for [NCERT; CPMT 1993; MP PMT 2004; AMU (Med) 2009]
 - (a) Conservation of water
- (b) Conservation of heat
- (c) Regulation of temperature (d) Regulation of amino acids
- In earthworm, gizzard is found in
- [CPMT 2009]

- (a) 8 10 Segment
- (b) 8th segment
- (c) 27th segment
- (d) 8 11 segment
- 55. In earthworm, ovary is situated in segment

[NCERT; AFMC 1993; AIIMS 1993; BHU 2012]

(a) 13

(b) 9

(c) 10

(d) 26

	DI LAN III		
56.	Blood of Pheretima is [NCERT;	67.	In Earthworm, arrangment of blood vessels is
	CBSE PMT 1990; Odisha JEE 2005]		[BHU 1994, 2000, 01
	(a) Blue with haemocyanin in corpuscles		(a) Different in last fifteen segments (b) Different in first thirteen segments
	(b) Blue with haemocyanin in plasma		(c) Same throughout
	(c) Red with haemoglobin in corpuscles		(d) Different in middle thirteen segments
	(d) Red with haemoglobin in plasma.	68.	Chloragogen cells are involved in
7.	Suctorial mouth occurs in [AFMC 2000]	00.	[RPMT 1995; APMEE 1995; DPMT 1999
	(a) Butterfly (b) Leech		(a) Digestion (b) Excretion of water
	(c) Taenia (d) Cockroach		(c) Respiration (d) Fat storage
58.	The animal which does not show any metamorphosis of	69.	Excretory organs of Earthworm are
	larval stage is [Pb. PMT 1997]		[NCERT; RPMT 1995; Manipal 1995, 99
	(a) Pheretima posthuma (b) Asterial		(a) Coelom (b) Flame cells (c) Nephridia (d) Gizzard
	(c) Musca domestica (d) Butterfly	70.	Spermathecae in earthworm is [NCERT; AFMC 2005]
59.	Which one of the following groups of structures/organs have	70.	(a) For producing sperm
1000	similar function [AIIMS 2005]		(b) For storage of sperm obtained from male earthworn
	(a) Typhlosole in earthworm, intestinal villi in rat and		during copulation and used in future
	contractile vacuole in Amoeba		(c) Both (a) and (b)
	(b) Nephridia in earthworm, Malpighian tubules in		(d) None of these
	cockroach and urinary tubules in rat	71.	In Earthworm, the effective organ for food digestion is
	(c) Antennae of cockroach, tympanum of frog and clitellum		[RPMT 1995
	of earthworm		(a) Pharynx (b) Buccal cavity
	(d) Incisors of rat, gizzard (proventriculus) of cockroach and	70	(c) Mouth (d) Stomach
	tube feet of starfish	72.	Life span of Earthworm is [RPMT 1996
50.	Earthworms have how many segments		(a) $1-3$ years (b) $2-8$ years (c) $3.5-10.5$ years (d) $6-8$ years
	[NCERT; HPMT 2005]	73.	Copulation period of Earthworm is [APMEE 1996]
	(a) 85 - 400 (b) 100 - 200	70.	(a) One hour (b) Two hours
	(c) 20 - 95 (d) 115 – 120		(c) Four hours (d) About one week
51.	Specialised respiratory organs are absent in [CPMT 2000]	74.	In Pheretima nephridia occur in [APMEE 1996]
	Or		(a) All segment except 1 – 4 and 10 – 14
	In which of the following respiration occurs without any		(b) $1-2, 4-6, 15$ to last segments
	respiratory organ [BHU 2006] (a) Mosquito larva (b) Tadpole		(c) Meganephridia in pre-clitellar and micronephridia in
	(a) Mosquito larva (b) Tadpole (c) Cockroach (d) Earthworm		post-clitellar segments
62.	Blood of Earthworm is red because its haemoglobin is		(d) Micronephridia in all segments meganephridia from
02.		75	clitellar region to end In Earthworm [APMEE 1996]
	(a) Intracellular (b) Intercellular	75.	In Earthworm [APMEE 1996] (a) Ovaries are larger than testes
	(c) Oxidised (d) Reduced		(b) Testes are larger than ovaries
63.	Earthworm found in India is [NCERT; RPMT 1995]		(c) Both are equal
	(a) Lumbricus (b) Pheretima		(d) Right testes are larger the ovaries
	(c) Drawida (d) Megascolex	76.	Trochophore larva is found in [DPMT 2004]
54.	Which one assists in locomotion		(a) Annelida (b) Platyhelminthes
	[CBSE PMT 1993; DPMT 1995]		(c) Coelenterate (d) Prawn
	(a) Trichocysts in Paramecium	77.	Name the animal having both setae and nephridia
	(b) Pedicellariae of Star Fish		[DPMT 1996]
	(c) Clitellum in Pheretima		(a) Sea Urchin (b) Sea Mouse
	(d) Posterior sucker in Hirudinaria		(c) Sea Anemone (d) Sea Pen
55.	Trait common amongst Earthworm, Leech and Centipede is	78.	Spermathecal pores of Pheretima are present in [INCERT;
E La	[CBSE PMT 1993]		CPMT 1996, 98; AMU (Med.) 2005; Kerala PMT 2010] (a) 5/6, 6/7 7/8 and 8/9
	(a) Absence of legs (b) Hermaphrodite nature		(a) 5/6, 6/7 7/8 and 6/9 (b) 6/7, 7/8. 8/9 and 9/10
	(c) Ventral nerve cord (d) Malpighian tubules		
66.	Leech secretes which of the following anticoagulant		(c) 1/2, 2/3, 3/4 and 4/5
	[AFMC 2005]	70	(d) 14/15, 15/16, 16/17 and 17/18 Turblesele found in Physicing accurs in COMT 1996.
	(a) Hirudin (b) Heparin	79.	Typhlosole found in <i>Pheretima</i> occurs in [CPMT 1996] (a) Oesophagus (b) Stomach
	(c) Serotonin (d) Histamine		(c) Gizzard (d) Intestine
			(d) Intestite

[RPMT 2000]

- Chromophil cells present on pharynx of Earthworm take part in secretion of [RPMT 1996] (a) Mucus
- (b) Lipases
- (c) Carbohydrases
- (d) All the above
- Nephrostome occurs in
- [RPMT 1998]
- (a) Septal nephridia
- (b) Integumentary nephridia
- (c) Pharyngeal and septal nephridia
- (d) Pharyngeal and integumentary nephridia
- Animals having multiple or numerous setae are included under [RPMT 1998]
 - (a) Polychaeta
- (b) Oligochaeta
- (c) Hirudinea
- (d) Onychophora
- Movement of coelomic fluid helps in locomotion of 83.
 - [JIPMER 1999]

- (a) Hydra
- (b) Frog
- (c) Starfish
- (d) Earthworm
- Which of the following annelids is a parasite on snails and [MP PMT 2013]
 - (a) Acanthobdella
- (b) Pontobdella
- (c) Branchellion
- Glossiphonia
- Which one is not deuterostome 85.
- [AFMC 1999]
- (a) Chordata (c) Annelida
- (b) Cephalochordata (d) Echinodermata
- In Earthworm, mouth is situated on [NCERT; APMEE 1999]
 - (a) Prostomium
- (b) Peristomium
- (c) Stomium
- (d) Protostomium
- 87. A mismatch is (a) Odd toe-Horse
- [Chd. CET 2000]
- (b) Pheretima-parapodia
- (c) Hydra-Cnidaria
- (d) Cartilaginous Fish-Shark
- 88. The nerve chord in earthworm originates from

[NCERT; AMU (Med.) 2012]

- (a) Supra-pharyngeal ganglia and has a fused pair of ganglia in each segment from the 3rd to the last
- (b) Supra-pharyngeal ganglia and has a fused pair of ganglia in each segment from the 4th to the last
- (c) Sub-pharyngeal ganglia and has fused pair of ganglia in each segment from the 5th to the last
- (d) Sub-pharyngeal ganglia and has a fused pair of ganglia in each segment from the 6th to the last
- 89. Pheretima and its close relatives derive nourishment from [NCERT; CBSE PMT (Pre.) 2012]
 - (a) Sugarcane roots
 - (b) Decaying fallen leaves and soil organic matter
 - (c) Soil insects
 - (d) Small pieces of fresh fallen leaves of maize, etc
- In Earthworm, neurons are
- [CPMT 2000; BHU 2006]
- (a) Sensory
- (b) Motor
- (c) Both (a) and (b)
- (d) Mixed
- In Pheretima, septa are absent (a) 5/6, 10/11
 - [CPMT 2000] (b) 5/6, 7/8
- (c) 6/7, 7/8
- (d) First four segments
- Enteronephric nephridia of earthworm are concerned with [CBSE PMT 2000]
 - (a) Excretion
- (b) Respiration
- (c) Digestion
- (d) Osmoregulation
- Blood vessel in Pheretima having valves is [AIIMS 2000]
 - (a) Dorsal
- (b) Ventral
- (c) Lateral
- (d) Integumentary

Oxygen carrying blood pigment of Earthworm is

[Kerala PMT 2000]

Or

- Which of the follwoing is absent in the coelomic fluid of earthworm [AFMC 2012]
- (a) Haemocyanin
- (b) Haemoglobin
- (c) Haemoerythrin
- (d) Chlorocruorin
- (e) Pinnaglobin

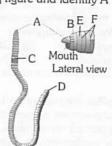

95.

- Nephridia of Pheretima are
- (a) Protonephridia
- (b) Solenocytes
- (c) Micrometanephridia
- (d) Meganephridia
- In Earthworm the dorsal wall of the intestine from the 26th segment to 95th segment forms a median internal fold called
 - (a) Trochophore
- [Kerala CET 2005, 07] (b) Typhlosole
- (c) Clitellum
- (e) Nephridium
- (d) Trachea
- Which is not correct for Earthworm [CPMT 2001]
 - (a) It walks with a speed of 25 cm/min
 - (b) It can remain without oxygen for 6-30 hrs
 - (c) Life span is 3.5 10 years
 - (d) Setae easily dissolve in KOH
- In Pheretima coelomic fluid contains [BHU 2001]
 - (a) Dissolved haemoglobin (b) Dissolved RBC
 - (c) Broken WBC
- (d) Watery plasma [Odisha JEE 2011]
- Locomotory organ of annelida is (a) Sucker
 - (b) Parapodia
- (d) All of these 100. External segmentation is absent but internal segmentation is present in [APMEE 2001]
 - (a) Polychaeta

(c) Setae

- (b) Oligochaeta
- (c) Archiannelida
- (d) Hirudinea 101. See the following figure and identify A to F
- [NCERT]

[APMEE 2002]

Dorsal view of earthworm

0	A	В	C	D	E	F

In which phylum the body is segmented (a) Porifera (b) Coelenterata (c) Annelida (d) Mollusca Which one of the following species of earthworm is not recommended for vermicomposting (a) Eudrilus eugeniae (b) Eisenia fetidae (c) Perionyx excavatus (d) Pheretima posthuma Which of the following is incorrect for Pheretima [CPMT 2010] (a) Genital papillae are present on 17th and 19th segment (b) Male genital pores are present on 18th segment (c) Clitellum is present on segments 24, 25 and 26 (d) Segments of earthworm are called somites The breakdown of detritus into smaller particles by earthworm is a process called [CBSE PMT (Mains) 2011; NEET 2013; KCET 2015] (a) Mineralisation (b) Catabolism (c) Humification (d) Fragmentation Which one of the following structures in Pheretima is correctly matched with its function [CBSE PMT (Mains) 2011] (a) Setae – defence against predators (b) Typhlosole – storage of extra nutrients (c) Clitellum – secretes cocoon (d) Gizzard – absorbs digested food Phylum-Arthropoda Which of the following features is not present in periplaneta Americana [NEET (Phase-I) 2016] (a) Schizocoelom as body cavity (b) Indeterminate and radial cleavage during embryonic	11.	honey bee (a) Compound eyes (c) Jointed legs Which one of the following goretly matched with morphological feature Animals (a) Scorpion, Spider, Cockroach, Locust, Taeniach, Locust, Taeniach, Liver fluke, Sea anemon Sea cucumber (d) Centipede, Prawn, Sea urd A moth is closely related to (a) Butterfly (c) Beetle Which one of the following animal concerned [NCERT; (a) Rat – Left kidney is sligging right one (b) Cockroach – 10 pairs of 8 pairs on abdomen) (c) Earthworm – The aligneed sequence of pharynx, or intestine	(b) Poison glands (d) Metamorphosis groups of three animals each is their one characteristic [CBSE PMT 2008] Morphological feature ach Ventral solid central nervous system a Metameric segmentation one, Bilateral symmetry hin Jointed appendages (b) Cricket (d) Wasp is the true description about an Manipal 2005; CBSE PMT 2008] htly higher in position than the spiracles (2 pairs on thorax and

(c) Leishmania donovani (d) Trypanosoma cruzi

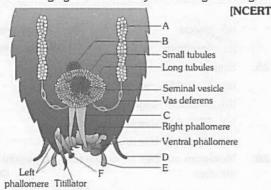

164			BOOK DEPOT 1960
14.	The biggest phylum in regard to the number of species is [NCERT; CPMT 1994]	24.	Book-lungs are respiratory organs which are found in [AFMC 2009]
	Or many		(a) Insects (b) Crustaceans
	Which one of the following have the highest number of		(c) Arachnids (d) Onychophores
	species in nature [CBSE PMT (Pre.) 2011]	25.	Stink gland is found in [CPMT 2009]
	(a) Arthropoda (b) Platyhelminthes		(a) 4th and 5th terga of cockroach
	(c) Chordata (d) Protozoa		
15.	The arthropods do not possess [EAMCET 1998]		(b) 5 th and 6 th terga of cockroach
	(a) True coelom (b) Exoskeleton		(c) 5 th and 6 th sterna of cockroach
	(c) Haemocoel (d) Malpighian body		(d) 4th and 5th sterna of cockroach
16.	The number of abdominal segments in male and female cockroach is [NCERT; Kerala PMT 2008]	26.	the class [MP PMT 2006]
	(a) 10, 10 (b) 9, 10		Or
	(c) 10, 11 (d) 8, 10		Which of the following classes has largest number of animals
	(e) 9, 9		(a) Diplopoda (b) Chilopoda
17.			(c) Crustacea (d) Insecta
	housefly [APMEE 1995; CPMT 1999; MH CET 2003]	27.	
	(a) Labrum (b) Epipharynx		[RPMT 1995, 99; AFMC 1996; KCET 1997;
	(c) Mandibles (d) Maxillary palps		RPMT 1999; BVP 2002]
18.	Which of the following animals is unisexual		(a) Cockroach, beetle (b) Bed bug
10.	[Kerala PMT 2008]		(c) Mosquito, wasp (d) Spider, Tick
	(a) Tapeworm (b) Leech	28.	Which of the following features is not present in the phylum
	(c) Sponge (d) Earthworm		- Arthropoda [NEET (Phase-I) 2016]
	(e) Cockroach		(a) Chitinous exoskeleton
19.			(b) Metameric segmentation
19.	Which of the following is not a characteristic features of arthropods [J & K CET 2012]		(c) Parapodia
	(a) Jointed appendages (b) Unsegmented body		(d) Jointed appendages .
00	(c) Moulting (d) Articulated exoskeleton	29.	What is the similarity between cockroach, anopheles and housefly [CPMT 1996]
20.	Note the following:		(a) Cuticle covering the body
	(A) Fenestra (B) Pedical (C) Lacinia		(b) Two pair wings
	(D) Flagellum (E) Gelea (F) Mentum		(c) Three pair legs(d) Presence of cephalothorax
	(G) Palpifer (H) Cando (I) Glossa		The common characters found in centipede, cockroach, and
	Which of the above found in the first pair of maxillae in the case of Cockroach [EAMCET 2009; AMU (Med.) 2010, 12]		crab are [CBSE PMT 2006]
	(a) C, E G and H (b) A, C, E and I		(a) Green gland and tracheae (b) Book lungs and antennae
	(c) A, F, G and I (d) B, E, G and I		(c) Compound eyes and anal cerci
21.	In cockroach, which of the following is the principal motor		(d) Jointed legs and chitinous exoskeleton
	centre [EAMCET 2009]	31.	Crayfish is a [MP PMT 1998]
	(a) Supraoesophageal ganglia	bon ,	(a) Crustacean animal (b) Edible fish
			(c) Poisonous fish (d) None of the above
	(b) Suboesophageal ganglia	32.	Which one of the following has an open circulatory system
	(c) Metathoracic ganglia		[CBSE PMT 2006] (a) Hirudinaria (b) Octopus
	(d) Abdominal ganglia		
22.	The terga, sterna and pleura of cockroach body are joined by [AIPMT (Cancelled) 2015]		(c) Pheretima (d) Periplaneta In which of the following sets all are vectors
			[NCERT; CPMT 1998]
	(a) Muscular tissue (b) Arthrodial membrane		(a) Physalia, Musca domestica, Anopheles
	(c) Cartilage (d) Cementing glue		(b) Amoeba, Physalia, Musca
23.	Spiders and scorpions are included in class		(c) Anopheles, Musca, Culex
2002.48(I)	[CBSE PMT 1993; CPMT 2010]	200	(d) All of the above
	(a) Arachnida (b) Echarida	34.	Phlebotomus argentipus is a vector for [EAMCET 1998]
			(a) Trypanosoma evansi (b) Trypanosoma gambiense

(d) Anthozoa

(c) Actinozoa

35. See the following figure and identify A to F in given diagram

	A	В	С	D	E	F
(a)	Testis	Phallic gland	Ejaculatory duct	Caudal style	Anal cercus	Pseudo penis
(b)	Testis	Phallic gland	Ejaculatory duct	Anal cercus	Caudal style	Pseudo
(c)	Testis	Collaterial gland	Ejaculatory duct	Terga	Caudal style	Pseudo penis
(d)	Testis	Collaterial gland	Ejaculatory duct	Anal	Caudal style	Pseudo

- 36. Respiration pigment of blood in cockroach is [RPMT 2006]
 - (a) Haemozoine
- (b) Haemocyanin
- (c) Haemoglobin
- (d) Absent
- 37. Which is a matching set in taxonomy [CMC Vellore 1993]
 - (a) Leech, locust, sea urchin, lobster
 - (b) Star fish, jelly fish, cuttle fish, octopus
 - (c) Milliped, crab, centipede, cockroach
 - (d) Nereis, planaria, round worm, earthworm
- 38. Book lungs are the respiratory organs in

[NCERT; RPMT 2006]

- (a) Protozoans
- (b) Cnidarians
- (c) Arthropodes
- (d) Amphibians
- 39. The taste receptors of cockroach are
- [DPMT 2006]

- (a) Compounds eyes
 - (b) Companiform sensillae
 - (c) Palps of maxillary and labium
 - (d) Tactile hairs
- Bilateral symmetry, metameric segmentation coelom and open circulatory system are the characters of [MP PMT 2009]
 - (a) Annelida
- (b) Arthropoda
- (c) Mollusca
- (d) Echinodermata
- **41.** Pasteurella/Yersinia pestis (causal agent of Bubonic Plague) is transmitted by [APMEE 1995]
 - (a) Bed bug/Cimex
- (b) Rat flea/Xenopsylla
- (c) Louse/Pediculus
- (d) Mosquito/Aedes
- 42. Among the following, colonial insects are
 - insects are [BHU 2006]
 - (a) Locusts
- (b) Mosquitoes
- (c) White ants
- (d) Bed bug
- 43. Complete metamorphosis is observed in
 - (a) Silver Fish
- (b) Gypsy Moth
- (c) Bed Bug
- (d) Grasshopper

44. Basic unit in the eye of Cockroach/insect is

eye of Cockroach/insect is [NCERT; APMEE 1995; Pb. PMT 1999; HPMT 2002]

- (a) Retina
- (b) Rhabdome
- (c) Corneal facet
- (d) Ommatidium
- 45. Malpighian tubules are
- [NCERT: BHU 2006]
- (a) Excretory organs of insects
- (b) Excretory organs of frog
- (c) Respiratory organs of insects
- (d) Endocrine glands of insects
- 46. Structure common between Earthworm and Cockroach is

[NCERT; CPMT 1994; AFMC 1994; RPMT 2005]

Or

Which one of the following features is common to earthworm, butterfly, spider and prawn [WB JEE 2016]

Or

Which one feature is common to leech Cockroach and scorpion [AIIMS 2004, 08]

- (a) Cocoon
- (b) Ommatidia
- (c) Dorsal nerve cord
- (d) Ventral nerve cord
- 47. Tumbler is pupa of
 - (a) Housefly
- (b) Mosquito
- (c) Butterfly
- (d) Beetle
- 48. What is common between earthworm and Periplaneta

[AIIMS 2012]

- (a) Both have red coloured blood
- (b) Both possess anal styles
- (c) Both have Malpighian tubules
- (d) Both have segmented body
- In cockroach, larval and nymphal characters are maintained by [BHU 2006]
 - (a) Ecdysone
- (b) Salivary glands
- (c) Parotid gland
- (d) Juvenile hormone
- The correct sequence of arrangements of segments in the leg of cockroach is [Kerala PMT 2006]
 - (a) Tibia, Trochanter, Femur, Tarsus and Coxa
 - (b) Trochanter, Coxa, Tibia, Femur and Tarsus
 - (c) Coxa, Femur, Trochanter, Tibia and Tarsus
 - (d) Coxa, Trochanter, Femur, Tibia and Tarsus
 - (e) Trochanter, Coxa, Femur, Tarsus and Tibia
- **51.** Mouth parts of a butterfly are of type
 - (a) Sponging
- (b) Siphoning
- (c) Piercing and sucking
- (d) Chewing and sucking
- 52. Conglobate gland occurs in
- [BCECE 2005; BHU 2008]
- (a) Female cockroach
- (b) Male cockroach
- (c) Anopheles mosquito
- (d) Culex mosquito s and Culex is [AFMC 2010]
- 53. Similarity between Anopheles and Culex is
 - (a) Eggs are laid in floating raft
 - (b) Respiratory siphon is present
 - (c) Eggs have lateral air floats
 - (1) M. I. C. III II II II II II
 - (d) Males of both suck juices of flowers and fruits
- 54. In Housefly the larva lives in
- [BHU 1995]

- (a) Water
- (b) Muddy soil
- (c) Dung
- (d) Vegatation

- In Pheretima, septa are absent between which segments [BHU 2006]
 - (a) 3/4 and 9/10 (c) 5/6 and 7/8
- (b) 4/5 and 8/9 (d) 7/8 and 6/7
- The ingrowth of exoskeleton in the head of cockroach is **IAFMC 20121**
 - (a) Notum
- (b) Apodemes
- (c) Pleura
- (d) Tentorium
- 57. An insect without pupa stage is
 - (a) Mosquito
- (b) Silk Moth
- (c) Bed Bug
- (d) Butterfly
- Young Housefly/Mosquito is known as (a) Maggot
 - (b) Caterpillar
 - (c) Nymph
- (d) Imago
- 59. Which set includes pathogenic Arthropods [AFMC 2006] (a) Tse-tse fly, mosquito, flea-plague
 - (b) Crab, Culex, spider

 - (c) Anopheles, Culex, cray fish
 - (d) Silver fish, house fly, sandfly
- Which of the following causes parasitic castration of crab [BHU 2012]
 - (a) Sacculina
- (b) Adamsia
- (c) Spongilla
- (d) None of these
- Ecdysone is produced by
 - (a) Prothoracic gland
- (b) Corpora allata
- (c) Corpora cardiaca
- (d) Abdominal gland
- 62. Cockroach is
 - (a) Carnivorous
- (b) Herbivorous
- (c) Omnivorous
- (d) Sanguivorous [Bihar MDAT 2002]
- 63. Johnston's organ found in (a) Antenna of Mosquito
- (b) Head of Cockroach
- (c) Abdomen of Housefly
- (d) Abdomen of Spider
- 64. Which disease is spread by Housefly
- [CPMT 1993]
 - (a) Dengue fever
- (b) Encephalitis (d) Gangrene
- (c) Filariasis
- 65. Halteres in Mosquitoes and Housefly develop from
 - (a) Prothorax
- (b) Metathorax (d) Head
- (c) Mesothorax 66. Mouth parts of Cockroach are of
 - [NCERT; BHU 1999; RPMT 2000; CPMT 2001]
 - (a) Piercing and sucking
- (b) Sucking and siphoning
- (c) Cutting and biting type (d) Sucking and rasping
- In insect, oxygen is carried to different tissues by

In Insects, respiratory gas exchange occurs through

[HPMT 2002]

- (a) Diffusion through surface
- (b) Tracheal tubes
- (c) Respiratory pigment through blood
- (d) Gills
- 68. Wings are vestigeal in Cockroach

[CPMT 1997]

- (a) Female Blatta orientalis
 - (b) Male Blatta orientalis
 - (c) Male Periplanata americana
 - (d) Female Periplanata americana
- Anal cerci occur in
 - (a) Both male and female cockroaches
 - (b) Male Cockroach
 - (c) Female Cockroach
 - (d) Female Ascaris

In the life cycle of mosquito, comma-shaped stage is

[DPMT 2004]

- (a) Larval stage (c) Imago stage
- (b) Pupal stage (d) None of these
- 71. The order of metamorphosis in Housefly is

[AIIMS 1999; JIPMER 2000]

- (a) Egg, nymph, pupa and adult
- (b) Egg, larva, nymph and adult
- (c) Egg, larva, pupa and adult
- (d) Egg, pupa, larva and adult
- 72. An aquatic living fossil, with ancient origin and many primitive characters which respires through book gills is

[NCERT; AMU (Med.) 2012]

- (a) Limulus
- (b) Cancer
- (c) Lucifer
- (d) Daphnia
- Hormone produced by corpora allata in insects is

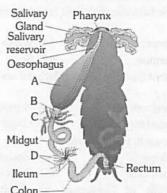

[APMEE 1996; AIIMS 1997; Manipal 2001; AMU (Med.) 2009]

[RPMT 1995; AFMC 2002]

- (a) Growth hormone
- (b) Moulting hormone
- (c) Inhibiting hormone
- (d) Juvenile hormone
- Male and female Cockroaches can be distinguished externally through [CBSE PMT 1991; Pb. PMT 1994, 97; RPMT 1995, 98, 2001; CPMT 1996, 98; Kerala PMT 2007; Odisha JEE 2012; NEET (Karnataka) 2013]
 - (a) Anal styles in male
 - Anal cerci in female
 - Anal style and antennae in females
 - (d) Both (a) and (c)
- 75. Periplaneta shows
 - (a) Complete metamorphosis (b) Incomplete metamorphosis
 - No metamorphosis (c)
 - (d) Gradual metamorphosis
- 76. Housefly feeds on sugar by
 - (a) Crushing its crystals and then sucking the power
 - (b) Crushing and eating
 - Sucking (c)
 - (d) Dissolving in saliva and sucking
- Metamorphosis of insects is regulated through hormone

[CBSE PMT 1991; BHU 1998, 2001; RPMT 1998; Pb. PMT 1999]

- (a) Pheromone
- (b) Thyroxine
- (c) Ecdysone
- (d) All the above
- See the following figure and identify structure A, B, C and D [NCERT]

	Α	В	C	D
(a)	Gizzard	Crop	Malpighian tubules	Hepatic caecae
(b)	Crop	Gizzard	Malpighian tubules	Hepatic caecae
(c)	Crop	Gizzard		
(d)	Gizzard	Crop	Hepatic caecae	Malpighian tubules

79.	In Cockroach, the number	of ganglia are [AFMC 1993]	93.	The first animals to fly we	ere	[RPMT 1995
	(a) Two pairs thoracic and	four pairs abdominal		(a) Mammals	(b)	Lizards
	(b) Three pairs thoracic ar	nd six pairs abdominal		(c) Birds	(d)	Insects
	(c) Three pairs thoracic ar	nd five pairs abdominal	94.	Which is nonpoisonous		[MP PMT 1995
	(d) Two pairs thoracic and	d six pairs abdominal		(a) Scorpion	(b)	Centipede
0.		ale Anopheles but absent in male		(c) Crab	(d)	Spider
	is	Land Cartes and Cartes And Cartes	95.	Which one is a tracheate	group	[MP PMT 1995
	(a) Maxillae	(b) Antennae		(a) King Crab – scorpior	n – Hous	efly
	(c) Proboscis	(d) Mandibles		(b) Crab - Centipede -	Cockroa	ch
1.	An insect regarded as grea	itest mechanical carrier of disease		(c) Spider – Peripatus -	Mosquite	
	is	[CBSE PMT 1991]		(d) Bed Bug - Sandfly -	Silkwor	m
	(a) Pediculus	(b) Cimex	96.	In Cockroach, metamorp	hosis rec	quires [RPMT 1996
	(c) Musca	(d) Xenopsylla		(a) Three weeks	(b)	40-70 days
2.	Which insect is called 'Horn	n Beetle' [CPMT 2005]		(c) 10-30 days	(d)	5-13 days
	(a) Tribolium	(b) Corcyra	97.	Male cockroach can be d	istinguisl	hed from female cockroacl
	(c) Trogoderma	(d) None of these		through		[RPMT 1996
3.	Which of the following is a	n r – strategist [DUMET 2010]		(a) Longer antennae	(b)	Longer abdomen
	(a) Human	(b) Insect		(c) Wingless body	(d)	All the above
	(c) Rhinoceros	(d) Whale	98.	Cockroach blood does	not cont	ain respiratory pigment.
1.	The major excretory produ			means		[RPMT 1996; AFMC 1998
	, , , , , , , , , , , , , , , , , , ,	[NCERT; Bihar MDAT 1994]		(a) It does not respire		
	(a) Ammonia	(b) Urea		(b) Cockroach respires a	naerobio	cally
	(c) Uric acid	(d) Trimethylamine oxide		(c) Oxygen passes to all		PROPERTY AND ADDRESS OF THE PROPERTY OF THE PARTY OF THE
5.	Common feature between			(d) Oxygen reaches tissu	e throug	gh tracheoles
		[Pb. PMT 2004]	99.	Which is common among	gst Fly, M	Iosquito and Cockroach
	(a) Head	(b) Mouthparts				[CPMT 1996
	(c) Abdomen	(d) Three pairs of jointed legs		(a) Open excretory syste		
6.	Adult Culex and Anophe	les can be distinguished with the		(c) All belong to class in	secta (d)	13-chambered heart
		BSE PMT 1992, 93; KCET 1998]	100.	Periplaneta differs from B	latta in	[CPMT 1996
	(a) Mouth parts/colour	(b) Sitting posture			Blatta	and developed wings in
	(c) Antennae/wings	(d) Feeding habits		Periplaneta		
7.	A larval stage occurs in the	life history of all members of the		(b) Reverse of (a)		
	group	[CBSE PMT 1993]		(c) Anal styles		
	(a) Frog, Lizard and Cock	roach	- Marchael	(d) Anal cerci		
	(b) Ascaris, Housefly and	Frog	101.	Which is characteristic of	TO STATE OF THE PARTY OF THE PA	
	(c) Housefly, Earthworm a	and Mosquito				996, 2009; HP PMT 2005
	(d) Butterfly, frog and Mos	squito		(a) 13-chambered heart		Reduced wings
8.	AND THE PROPERTY OF STREET AND ADDRESS OF THE PARTY OF TH	nd female Anopheles occurs in	100	(c) Cocoon formation		Segmented body
		[CBSE PMT 1993]	102.	Arrhenotoky is parthenog	enetic de	
	(a) Proboscis	(b) Wings		(a) All inqueta		[AIIMS 1996]
	(c) Antennae	(d) Size		(a) All insects (b) Mosquitoes		
9.	Tracheae of Cockroach and	d Mammal are similar in having				
		[CBSE PMT 1993]			and Anta	
	(a) Paired nature	(b) Noncollapsible walls	102	(d) Honey bees, Wasps a	and Ams	
	(c) Ciliated inner lining	(d) Origin from head	103.	Sandfly is (a) Ancyclostoma	(h)	[Bihar MDAT 1996] Musca
0.	Pupa occurs in the life cycle	e of [CPMT 1994]		(c) Phlebotomus	Visit in	Drosophila
	(a) Cockroach	(b) Housefly	104			
	(c) Honey Bee	(d) Both (b) and (c)	104.	In Cockroach the longest (a) Coxa		
1.		ch has both exoskeleton and		(c) Tibia		Trochanter of Femur
	endoskeleton	[RPMT 1995]	105	Tick the correct matching	(a)	Tarsus
	(a) Head	(b) Thorax	103.		Mitos	[DPMT 1996
	(c) Abdomen	(d) All the above		(a) Arachnida — Ticks, I		
2.		sent from [NCERT; RPMT 1995]		(b) Prototheria — Scaly		
	(a) Prothorax	(b) Mesothorax		(c) Prokaryotes — Green	The second second	
	(c) Metathorax	(d) None of the above		(d) Annelida — Ascaris,	I aenia	

UNIVERSAL BOOK DEPOT 1960

		Allithal Kingdom 233 UNIVERSAL BOOKDEPOT 1960
106	Which one possess larval stages [DPMT 1996]	118. Millipede (Julus) and Centipede (Scolopendra) are both
	(a) Cockroach and Housefly	included under [RPMT 1998]
	(b) Housefly and Butterfly	(a) Arachnida (b) Myriapoda
	(c) Cockroach and Honey Bee	(c) Scaphopoda (d) Pelecypoda
	(d) Grasshopper and Dragonfly	119. Spider prepares the web with the help of [JIPMER 1999]
107.	In Butterfly, long coiled siphoning tubes is formed from	(a) Legs (b) Mouth (c) Spinnerets (d) Salivary glands
	[APMEE 1996] (a) Labrum (b) Maxilla	(c) Spinnerets (d) Salivary glands 120. Open circulatory system is not of physiological hindrance in
	(c) Labium (d) Mandibles	Cockroach because [AIIMS 1999]
108.	If juvenile hormone is absent when silkworm moults, it will	(a) Heart is simple but chambered
	[CBSE PMT 1997]	(b) Blood is colourless
	(a) Moult into another larval stage	(c) Circulatory and respiratory systems are not connected
	(b) Moult into pupa	(d) Excretion occurs through malpighian tubules
	(c) Moult into adult	121. In cockroaches, digestive juice is secreted by the
	(d) Die	[NCERT; Kerala PMT 2012]
109.	Which is absent in arthropoda [JIPMER 1997]	(a) Gizzard (b) Malpighian tubules
	(a) Compound eye	(c) Crop (d) Oesophagus
	(b) Chitinous exoskeleton	(e) Hepatic caeca
	(c) Closed blood vascular system	122. Number of fertilized eggs in ootheca of Cockroach is
	(d) Malpighian tubules	[NCERT; BHU 1999; Kerala PMT 2000; Manipal 2001]
110.	Swarming is found in [MP PMT 1998]	(a) 16 pairs in two rows (b) 16 in two rows
	(a) Houseflies (b) Mosquitoes	(c) 10 in one rows (d) 8 in two rows
	(c) Locusts (d) Pyrilla	123. In Cockroach, ootheca is produced by secretion of
111.	Complete metamorphosis present in[CPMT 2002; RPMT 2006]	[APMEE 1999]

[NCERT; CPMT 2002; RPMT 2005; KCET 2012]

- (a) Labrum
- (b) Labium
- (c) Mandibles
- (d) Maxilla
- 158. Which of the following is an insect[CPMT 2002; RPMT 2005]
 - (a) Moth
- (b) Mites
- (c) Prawn
- (d) Scorpion
- 159. In cockroaches during the digestion of food, the enzyme cellulase in synthesised by [HP PMT 2005]
 - (a) Saliva
 - (b) Lining cells of midgut
 - (c) Bacteria in the midgut
 - (d) Cellulase is never synthesised
- 160. In crustaceans, respiration takes place by [RPMT 2002]
 - (a) Gills
- (b) Book lungs
- (c) Ctenidia
- (d) Trachea
- **161.** Which of the following is correctly stated as happens in the common cockroach [CBSE PMT (Pre.) 2011]
 - (a) The food in ground by mandibles an gizzard
 - (b) Malpighian tubules are excretory organ projecting out from the colon
 - (c) Oxygen is transported by haemoglobin blood
 - (d) Nitrogenous excretory product is urea
- 162. Cray Fish belongs to
- [BHU 1998; AMU (Med.) 2002]
- (a) Pisces
- (b) Mollusca
- (c) Arthropoda
- (d) Anthozoa
- 163. Which one does not occur in Cockroach leg [DPMT 2002]
 - (a) Tibia
- (b) Femur
- (c) Fibula
- (d) Coxa
- 164. Hind wings of mosquitoes are termed as

[CPMT 1999; BHU 2002]

- (a) Coxa
- (b) Elytra
- (c) Halteres
- (d) Tentorium
- 165. The given figures are related with mouth parts of cockroach. Identify A to E

Mouthparts of cockroach

[NCERT]

	A	В	C	D	Е
(a)	Labium	Hypopharynx	Labrum	Maxilla	Mandible
(b)	Labrum	Mandible	Hypopharynx	Maxilla	Labium
(c)	Mandible	Labium	Maxilla	Labrum	Hypopharynx
(d)	Maxilla	Hypopharynx	Labium	Mandible	Labrum

166. Match the columns and choose the exact combination

(A)	Ommatidia	(i)	Articulation with thorax
(B)	Trochanter	(ii)	For vision
(C)	Coxa	(iii)	Forming exoskeleton
(D)	Sclerites	(iv)	Fused with large and stout femur

[Manipal 2002]

- (a) A-(iv), B-(iii), C-(i), D-(ii)
- (b) A-(i), B-(ii), C-(iii), D-(iv)
- (c) A-(ii), B-(iv), C-(i), D-(iii)
- (d) A-(iii), B-(i), C-(ii), D-(iv)
- 167. Ommatidia serve the purpose of photoreception in

[CBSE PMT 2003; BHU 2012]

- (a) Sunflower
- (b) Cockroach
- (c) Frog
- (d) Humans
- 168. Mouth part of mosquito is

[CPMT 2002; MH CET 2003; RPMT 2005]

- (a) Sucking and piercing type(b) Sponging type
- (c) Biting and chewing type (d) None of these
- 169. Vision in cockroach is
- [BVP 2003]
- (a) Monocular
- (b) Binocular
- (c) Ultrasonic
- (d) Mosaic
- **170.** Which one of the following is a matching pair of an animal and a certain phenomenon it exhibits [CBSE PMT 2003]
 - (a) Taenia Polymorphism
 - (b) Pheretima Sexual dimorphism
 - (c) Musca Complete metamorphosis
 - (d) Chamaeleon Parthenogenesis
- 171. Haemocoel is found in

[CPMT 1999; DPMT 2004; Odisha JEE 2011]

- (a) Hydra and Aurelia
- (b) Taenia and Ascaris
- (c) Balanoglossus and Herdmania
- (d) Cockroach and Pila
- 172. Universal character of insect is

[MP PMT 2002;

MH CET 2004; AFMC 2005; Odisha JEE 2008]

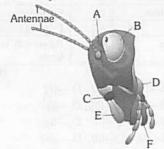

- (a) Two pair of wings
- (b) Compound eyes
- (c) Three pair of legs
- (d) Both (b) and (c)
- 173. Larvae of beetles are known as
- as [Kerala PMT 2004]
 - (a) Caterpillars
- (b) Grubs
- (c) Maggots
- (d) Naids
- 174. Scorpion belongs to a class to which one of the following also belong [DPMT 2003; BVP 2004]
 - (a) Ticks
- (b) Crab
- (c) Barnacles
- (d) Cockroach
- 175. Blood of which of the following is colourless

[HPMT 2005]

- (a) Earthworm
- (b) Leech
- (c) Cockroch
- (d) Frog
- 176. In Arthropoda, head and thorax are often fused to form cepalothorax, but one of the following classes is the body divide into head, thorax and abdomen [CBSE PMT 2004]
 - (a) Crustacea
 - (b) Arachnida and Crustachea
 - (c) Insecta
 - (d) Myriapoda

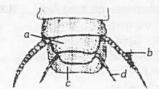

177. The given figure is associated with head region of cockroach. Identify A to F [NCERT]

	A	В	C	D	E	F
(a)	Ocellus	Compound eye	Maxilla	Mandible	Labium	Labrum
(b)	Ocellus	Compound eye	Mandible	Maxilla	Labium	Labrum
(c)	Ocellus	Compound eye	Mandible	Maxilla	Labrum	Labium
(d)	Compound eye	Ocellus	Maxilla	Mandible	Labrum	Labium

178. The diagram represents the reproductive organs of male cockroach. Choose the correct combination of labelling.

[Kerala CET 2005]

- (a) a-8th sternum, b-anal cercus, c-10th tergum, d-anal style
- (b) a-10th tergum, b-anal cercus, c- anal style, d-8th sternum
- (c) a-anal style, b-anal cercus, c-10th tergum, d-8th sternum
- (d) a-8th sternum, b-anal style, c-10th tergum, d-anal cercus
- (e) a-anal cercus, b-8th sternum, c-10th tergum, d-anal style
- 179. What is common between an earthworm, a cockroach and a centipede [AIEEE Pharmacy 2004]
 - (a) Sexual dimorphism
- (b) Metamorphism
- (c) Chitinous exoskeleton
- (d) Haemocoel
- 180. What is common between a moth, a frog and a mosquito

[AIEEE Pharmacy 2004]

- (a) The body is clearly differentiated into head, thorax and abdomen
- (b) The life history is carried out in water
- (c) The skin acts as the main respiratory organ
- (d) Their larvae feed on a food different from that of the adult
- 181. The peculiar pungent smell of cockroach is produced by the secretions of [CPMT 2004]
 - (a) Pheromones
- (b) Flame cells
- (c) Abdominal glands
- (d) Cervical glands
- 182. The cockroach of genus Blatta is also called [CPMT 2004]
 - (a) German cockroach
- (b) Australian cockroach
- (c) Orient cockroach
- (d) American cockroach
- 183. The young one of cockroach is called [NCERT; KCET 2004]
 - (a) Caterpillar
- (b) Nymph
- (c) Fingerling
- (d) Maggot

- 184. Which one of following feature is possessed by crustaceans and not by insects [CPMT 2005]
 - (a) Paired limbs
- (b) Two pairs of antenna
- (c) Chitinous exoskeleton
- (d) Bilateral symmetry
- 185. The head of cockroach lacks
- [CPMT 2010]

- (a) Cardo
- (b) Gena
- (c) Trochanter
- (d) Frons
- 186. The adhesive pads (soft-pads) present in legs of cockroach are [AFMC 2005; KCET 2010]
 - (a) Galea
- (b) Lacinea
- (c) Glossa
- (d) Plantulae
- 187. Which of the following are examples of arthropoda

[Odisha JEE 2010; NEET 2013]

- (a) Silver fish, star fish, prawn
- (b) Clam worm, apple snail, honeybee
- (c) Sea star, tongue worm, scorpion
- (d) Cockroach, scorpion, prawn
- 188. Insects are [HPMT 2005; MP PMT 2006]
 - (a) Amminotelic
- (b) Ammonotelic
- (c) Ureotelic
- (d) Uricotelic
- 189. Gizzard of cockroach is a part of(a) Respiratory system (b)
 - (b) Digestive system
 - (c) Immune system
- (d) Circulatory system
- Which one of the following features is common in silverfish, scorpion, dragonfly and prawn [AIIMS 2005]
 - (a) Three pairs of legs and segmented body
 - (b) Chitinous cuticle and two pairs of antennae
 - (c) Jointed appendages and chitinous exoskeleton
 - (d) Cephalothorax and tracheae
- 191. From the following statements select the wrong one

[CBSE PMT 2005]

[HPMT 2005]

- (a) Prawn has two pairs of antennae
- (b) Nematocysts are characteristics of the phylum cnidaria.
- (c) Millepedes have two pairs of appendages in each segment of the body
- (d) Animals belonging to phylum porifera are exclusively marine
- 192. Which structure of man is similar to the spiracle of cockroach [Odisha JEE 2005]
 - (a) Nostril
- (b) Bronchiole
- (c) Lungs
- (d) Alveoli
- 193. How do you differentiate a butterfly from a moth

[KCET 2010]

- (a) Moth has feathery antennae but butterfly has club shaped antennae
- (b) Moth has one pair of wings but butterfly has two pairs of wings
- (c) Moth is diurnal but butterfly is nocturnal
- (d) Moth has simple eyes but butterfly has compound eyes
- 194. Tubular heart of cockroach has how many chambers

[AFMC 2005]

- (a) 10
- (b) 13
- (c) 12
- (d) 11
- 195. Which of the following animal belongs to class crustacea
 - [WB JEE 2010]
 - (a) Cockroach
- (b) Cyclops
- (c) Grasshopper
- (d) Mosquito

- 196. Which of the following statements is correct regarding cockroach [CPMT 2010]
 - (a) Ventral nerve cord is present
 - (b) Spiracles help in excretion
 - (c) Phallomere is present in female cockroach
 - (d) Compound eye is also called as ocellus
- 197. Mushroom gland is a part of

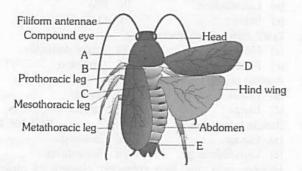

[CPMT 2010]

- (a) Male reproductive system of cockroach
- (b) Female reproductive system of cockroach
- (c) Male reproductive system of rabbit
- (d) Female reproductive system of rabbit
- 198. What external changes are visible after the last moult of a cockroach nymph
 - (a) Labium develops
 - (b) Mandibles become harder
 - (c) Anal cerci develop
 - (d) Both fore wings with hind wings develop
- 199. Which one of the following is one of the paths followed by air/O2 during respiration in an adult male Periplaneta americana as it enters the animal body

[NEET (Karnataka) 2013]

- (a) Spiracle in metathorax, trachea, tracheoles, oxygen diffuses into cells
- (b) Mouth, bronchial tube, trachea, oxygen enters cells
- Spiracles in prothorax, tracheoles, trachea, oxygen diffuses into cells
- (d) Hypopharynx, mouth, pharynx, trachea, tissues
- 200. See the following figure and identify A to E

[NCERT]

	A	В	С	D	E
(a)	Pronotum	Mesothorax	Metathorax	Tegmina	Anal style
(b)	Pronotum	Mesothorax	Metathorax	Tegmina	Anal cerci
(c)	Pronotum	Mesothorax	Metathorax	Tegmina	Sternum
(d)	Pronotum	Mesothorax	Metathorax	Tegmina	Pleura

201. Match Column-I with Column-II for housefly classification and select the correct option using the codes given below

INEET	(Phase-II)	20161

			LIVEL	(Fnase-II)
Col	umn-I		Colum	n-II
(A) Fam	nily		(i) Diptera

- 202. In male cockroaches, sperms are stored in which part of the reproductive system [NEET (Phase-II) 2016]
 - (a) Vas deferens

(b) Seminal vesicles

(c) Mushroom glands

(d) Testes

Phylum-Mollusca

- 1. Which one of the following is not used in organic farming [BHU 2006; AMU (Med.) 2006; CBSE PMT (Pre.) 2010]
 - (a) Snail

(b) Glomus

(c) Earthworm

(d) Oscillatoria

The devil fish and sea hare are

[NCERT; J & K CET 2008; AMU (Med.) 2012]

(a) Molluscs

(b) Crustaceans

- (c) Coelenterates
- (d) Marine fish and mammal
- Which one of the following phyla is correctly matched with its two general characteristics [CBSE PMT 2008]
 - Pentamerous radial symmetry and (a) Echinodermata mostly internal fertilization
 - (b) Mollusca Normally oviparous development through a trochophore or veligerlarva
 - (c) Arthropoda Body divided into head, thorax and abdomen and respiration by tracheae
 - (d) Chordata Notochord at some stage and separate anal and urinary opening to the outside
- Foot is displaced to the neighbourhood of mouth and divided into arms in [AIIMS 1999]
 - (a) Ostrea

(b) Pila

(c) Sepia

(d) Chiton

Most mollusc are

(a) Terrestrial

(b) Fresh water

[BVP 2003]

[RPMT 1999]

(c) Marine

(d) None of these

The elephant tusk shell is (a) Dentalium

(b) Nautilus

(c) Limax

(d) Octopus

- Cilia of gills of bivalve molluscs help in [DPMT 2006]
 - (a) Feeding

(b) Digestion

- (c) Reproduction (d) Excretion Which among the following is not a class of phylum 8.
 - mollusca [JIPMER 1993; AFMC 1997]
 - (a) Gastropoda

(b) Trematoda

(c) Decapoda

9.

- (d) Both (b) and (c)
- Which one is not correctly matched [Odisha JEE 2005] (a) Mollusca Pseudocoel
 - (b) Cnidaria Nematocust
 - (c) Annelida

Chloragogen cells

(d) Echinodermata -

Water vascular system

Ospharidium is meant for

[CPMT 2005]

- (a) Excretion
 - (b) Nutrition
- (c) Selection and rejection of food
- (d) Grinding of food
- 11. Which one belongs to the class of sea hare [MP PMT 1995] Or

Which of the following belongs to the class gastropoda [J & K CET 2012]

(a) Sea cow

(b) Sea squirt

- (c) Snail

- (d) Sepia

	90/33	200	93		
UN	IVI	RS	AL.

258 Animal Kingdom Asymmetry in gastropoda is due to Phylum mollusca can be distinguished from other [MH CET 2003] (a) Torsion (b) Coiling invertebrates by the presence of [RPMT 1998; DUMET 2010] (c) Twisting (d) Abdomen (a) Bilateral symmetry and exoskeleton 13. The mollusc which is considered to be a living fossil and also (b) A mantle and gills shows characters of annelids like nephridia and internal (c) Shell and non-segmented body segmentation is **[AIIMS 1993]** (d) A mantle and non-segmented body (a) Pinctada vulgaris (b) Nautilus As per classification which of the following is correct (c) Neopilina galatheca (d) None of these 14. Pila is the example of which class [RPMT 2001] (a) Ascaris, Pheretima, Grasshopper (a) Gastropoda (b) Pelecypoda (b) Hydra, Pterido, Leucosolenia (c) Cephalopoda (d) Scaphopoda (c) Starfish, Grasshopper, Solen 15. In which one of the following, the genus name, its two (d) Pila, Dentalium, Octopus characters and its phylum are not correctly matched, 25. Mantle, foot and shell are the character of whereas the remaining three are correct Or [NCERT; CBSE PMT (Pre.) 2012] Which of the following is a living fossil Genus Two characters Phylum (a) Nautilus (b) Echinus Name (c) Limulus (d) Euplectella Pila **Body Segmented** Mollusca (a) (a) Match the columns and choose the correct combination. Mouth with (b) Polychaeta Scorpion Radula p. B. Trematoda Pila q. Spiny Skinned (b) Asterias (a) Echinodermata C Arachnida Liver Fluke Water vascular r. D. Gastropoda Nereis S. system t. Star Fish Pore bearing Porifera Sucon Canal system (b) A-q, B-s, C-t, D-p (a) A-s, B-r, C-p, D-q (d) Periplaneta Jointed Arthropoda (c) A-r, B-s, C-p, D-t (d) A-t, B-q, C-s, D-r appendages Which of the following mollusc is formed by a larva which 27. Chitinous have torsion exoskeleton (a) Lamelledens (b) Pila Visceral mass undergo torsion in (c) Sepia (d) Octopus [DPMT 2003; AMU (Med.) 2010] 28. Cuttle Fish is a member of (a) Gastropoda (b) Cephalopoda (a) Mollusca (b) Echinodermata (c) Palacopoda (d) None of these (c) Pisces (d) Amphibia 17. Cephalopoda is a class of animals in which [MP PMT 1994] A wood boring mollusca/Shipworm is 29. (a) Notochord extends upto head (a) Chiton (b) Teredo (b) Foot is located on head (c) Limax (d) Patella (c) Head is located on foot 30. Radula is found in (d) Head is fused with thorax (a) Pila sp (b) Chiton sp 18. In mollusca, eye is present over a stalk called (c) Lamellidens sp (d) Pinctada sp [CPMT 2000; BHU 2006] 31. Haemocyanin, the blue colouring pigment of molluscan (a) Ostracum (b) Operculum blood contains (c) Osphradium (d) Ommatophores (a) Iron (b) Magnesium (c) Copper (d) Manganese 19. "Shell of mollusc is produced by its [BHU 2000; MH CET 2003] 32. Filter feeding occurs in (a) Radula (b) Thorax (a) Dentalium (b) Unio (c) Mantle (d) Abdomen (c) Pila (d) Amoeba 20. Which set is correct [CPMT 1998] 33. An animal without segmentation is (b) Paramecium-Flagella (a) Euglena--cilia (b) Earthworm (a) Tapeworm (c) Snail-Foot (d) Amoeba-Foot (c) Glow Worm (d) Shipworm 21. Which of the following is the oldest living fossil 34. Closed circulatory system occurs in [CBSE PMT 1994] [CMC Vellore 1993] (a) Snail (b) Cockroach (a) Architeuthis (b) Neopilina (c) Cuttle Fish (d) All the above (c) Nautilus (d) Limulus 35. Pila shows summer (b) Aestivation 22. Which of the following is correct (a) Hibernation [AIIMS 2001] (c) Emigration (d) Immigration (a) Mollusca - bivalvia-pila Octopus, Squid and Cuttle Fish belong to class (b) Annelida - hirudinea - silver fish [BHU 1998; RPMT 2001; AFMC 2001] (c) Mollusca - cephalopoda - octopus (a) Cephalopoda (b) Apoda

(c) Decapoda

(d) Arthropoda - arachnida - grasshopper

22. An animal phylum having radially symmetrical adults but bilateral symmetrical larvae is [NCERT; BVP 2001;

DPMT 2004; CBSE PMT 2004; Kerala PMT 2008; KCET 2012]

- (a) Porifera
- (b) Coelenterata
- (c) Echinodermata
- (d) Annelida
- 23. Cephalization is absent in
 - (a) Molluscs
- (b) Arthropods
- (c) Both (a) and (b)
- (d) Echinoderms
- 24. Which is unrelated
- (b) Sea Star
- (a) Sea Cucumber(c) Sea Urchin
- (d) Sea Squid
- 25. Echinodermata is a group of animals which are
 - [MP PMT 2004]

IRPMT 1996

- (a) Coelomate, horny, marine
- (b) Coelomate, spiny, marine
- (c) Acoelomate, spiny, fresh water
- (d) Joint legged, marine
- 26. Aristotle's lantern is connected with

[AIIMS 1999; APMEE 2002]

- (a) Respiration
- (b) Mastication
- (c) Excretion
- (d) Support
- 27. Echinoderms are headless, brainless and heartless. Yet they are placed at the top of invertebrates because of presence of [MP PMT 2000]
 - (a) Enterocoel
 - (b) Exclusive marine forms
 - (c) High power of regeneration
 - (d) Great power of reproduction
- Tube feet are the characteristic structures of [CBSE PMT 2000;
 MHCET 2001; BHU 2005; CPMT 2009; Odisha JEE 2010]
 - (a) Jellyfish
- (b) Cuttlefish
- (c) Starfish (Echinodermata) (d) Crayfish
- 29. Match the animals list with names under Column-I with the animals listed with regular zoological name given under Column-II; choose the answer which gives the correct combination of the alphabets of the two columns

	Column-I		Column-II
	Animals with	SI MARIN	Animals with
	common name		zoological name
A.	Starfish	p.	Sepia
B.	Jellyfish	q.	Astropecten
C.	Devilfish	r.	Aurelia
D.	Cuttlefish	S.	Octopus

[KCET 2000, 09]

- (a) A = r, B = s, C = p, D = q
- (b) A = r, B = p, C = s, D = q
- (c) A = q, B = r, C = s, D = p
- (d) A = q, B = p, C = s, D = r
- Antedon belongs to the class
 - [AIIMS 2000]
- (a) Crinoidea

30.

- (b) Asteroidea
- (c) Ophiuroidea
- (d) Echinoidea
- 31. Basket star belongs to class
- [AIIMS 1999; AFMC 2000]
- (a) Ophiuroidea
- (b) Echinoidea
- (c) Asteroidea
- (d) Crinoidea
- 32. Box like calcareous test occurs in
- n [HPMT 2001]
 - (a) Sea Lily
- (b) Sea Star
- (c) Sand Dollar
- (d) Sea Cucumber

- 33. In which class of echinodermata stalk is found for attachment with substratum [RPMT 2001]
 - (a) Asteroidea
- (b) Echinoidea
- (c) Ophiuroidea
- (d) Crinoidea
- Bipinnaria is the larva of
- [BHU 2001; Odisha JEE 2004]
- (a) Pila
- (b) Lemellidens
- (c) Sepia (d) Star fish (Asteroidea)
 35. Which one of the following statement is true about an organism and its classification

[AIEEE Pharmacy 2004; AMU (Med.) 2005]

- (a) Blue green alga is kind of fungus
- (b) Sea horse is closely related to dolphin
- (c) Maiden hair tree is a kind of angiosperm
- (d) Sea lily is a kind of echninoderm
- 36. In echinodermata, tube feet are related with [BVP 2003]
 - (a) Excretory system
- (b) Ambulacral system
- (c) Reproductive system
- (d) Respiratory system

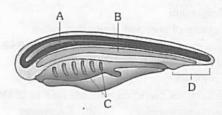

Phylum-Chordata

- Which one of the following pairs of animals comprises 'jawless fishes' [NCERT; CBSE PMT 2009]
 - (a) Lampreys and eels
- (b) Mackerals and Rohu
- (c) Lampreys and hag fishes (d) Guppies and hag fishes
- 2. The number of gills present in Osteichthyes is

[Kerala PMT 2008]

- (a) 2 pairs
- (b) 6-15 pairs
- (c) 5 pairs
- (d) 4 pairs
- (e) 12 pairs
- At retrogressive metamorphosis the urochordate larva
 - [AFMC 2006]

- (a) Loss notochord
- (b) Loss tail
- (c) Experience reduction of nervous system to a visceral genglion
- (d) All of the above
- 4. Animals belonging to phylum Chordata are fundamentally characterized by the presence of structure noted as A, B, C and D. Identify the names of A, B, C and D [NCERT]

- (a) A Nerve cord, B Gill slits, C Notochord, D Postanal part
- (b) A Nerve cord, B Notochord, C Post-anal part, D Gill slits
- (c) A Nerve cord, B Notochord, C Gill slits, D Postanal part
- (d) A Notochord, B Nerve Cord, C Gill Slits, D Postanal part
- In which of the following jaws are found
 (a) Herdmania (b) Fish
 - (b) Fish

[RPMT 1999]

- (c) Petromyzon
- (d) Amphioxus

[DPMT 2004]

(b) Hemichordata

(d) Protochordata

Temperature changes in the environment affect most of the 6. In some chordates, the notochord is modified as the 18. animals which are [CBSE PMT 1999; CPMT 2001] vertebral column. Such animals are called vertebrates. (a) Aquatic (b) Desert living Which one of the following statements make sense (c) Poikilothermic (d) Homoiothermic [NCERT; KCET 2003, 11] 7. The animal who possesses notochord throughout life is (a) All chordates are vertebrates but all vertebrates are not [EAMCET 1998; CPMT 1999; CBSE PMT 2000; chordates MH CET 2003; BHU 2005; Odisha JEE 2010] (b) All vertebrates are chordates and all chordates are Or Which of the following animals is not a vertebrate [NCERT] vertebrates (a) Fish All vertebrates are chordates but all chordates are not (b) Amphioxus (c) Bird vertebrates (d) Snake 8. Which of the following statements is / are not true (d) Chordates are not vertebrates and vertebrates are not In Urochordata, notochord is present only in larval tail. chordates B. In Cephalochordata, notochord extends from head to Petromyzon belongs to [MH CET 2004] tail region. (a) Agnatha (b) Gnathostomata C. Branchiostoma belongs to Hemichordata (c) Protochordata (d) Euchordata D. Only one Class of living members, Class Cyclostomata The echinoderms, hemichordates and chordates had which represents the Super Class Agnatha of the following larva as common ancestral form [NCERT; Kerala PMT 2006] (a) A, B and D only [APMEE 1996; BHU 1999; CBSE PMT 2001] (b) C, D and A only (c) Conly (a) Tornaria (d) A and D only (b) Trochophore (e) C and D only (c) Dipleurula (d) Bipinnaria Blood vascular system in hemichordata is [AFMC 2006] 21. Which among the following is the only vertebrate (a) Open (b) Reduced osmoconformer [DPMT 2004] (c) Closed (d) Absent (a) Rabbit (b) Hagfish The most important distinctive character of chordata is the 10 (c) Bird (d) None of these presence of [CBSE PMT 1991] 22. Which one of the following feature is found in chordates but (a) Vertebral column (b) Hairy skin not in non-chordates (c) Notochord (d) All the above [KCET 2007] (a) Gills 11. Retrogressive metamorphosis is found in (b) Spiracles (c) Post anal tail [RPMT 1999, 2006; WB JEE 2010] (d) Chitinous exoskeleton (a) Balanoglossus (b) Branchiostoma Which of the following show relationship of echinoderms (c) Herdmania (Urochordata)(d) All of these and chordates [DPMT 1993] The lamprey (Petromyzon) is included in the same 12. (a) Balanoglossus (b) Archaeopterux taxonomic class as the (c) Peripatus (d) None of these (a) Chamaeleon (Anolis) (b) Hag fish (Myxine) 24. Crocodile and penguin are similar to Whale and Dogfish in (c) Salamander (Ambystoma) (d) Lung fish (Neoceratodus) which one of the following features The portal system seen in all vertebrates is [JIPMER 1993] 13. [NCERT; CBSE PMT (Mains) 2010] (a) Hepatic (b) Renal (a) Possess a solid single stranded central nervous system (c) Both (a) and (b) (d) Pulmonary (b) Lay eggs and guard them till they hatch Which one of the following is not a characteristic feature of (c) Possess bony skeleton the sub phylum vertebrata [NCERT; Kerala PMT 2007] (d) Have gill slits at some stage (a) Dorsal tubular nerve cord Which of the following sets of animals belong to class 25. (b) Ventral muscular heart cyclostomata [NCERT: (c) Presence of notochord in the adult DPMT 1993; BHU 2000; J & K CET 2008] (d) Presence of kidneys (a) Herdmania and petromyzon (e) Two pairs of lateral appendages, fins or limbs (b) Petromyzon and myxine Notochord is restricted to the anterior part of body proboscis (c) Amphioxus and balanoglossus in animals of which group (d) Herdmania and myxine [RPMT 1995] The jawless vertebrate is (a) Hemichordata 26. (b) Urochordata [Kerala PMT 2004] (c) Cephalochordata Or (d) Chordata Animals having a built-in thermostat to maintain constant 16. A jawless fish, which lays eggs in fresh water and whose body temperature are known as ammocoetes larvae after metamorphosis return to the [KCET 1999: CPMT 2003; BHU 2006; AFMC 2012] ocean, is [AIPMT 2015] (a) Biothermic (b) Poikilothermic (a) Crocodile (b) Loris (c) Oligothermic (d) Homoeothermic (c) Hyla (d) Fox Which of the following groups has no member having 17. (e) Petromyzon gliding or flying appendages Herdmania belongs to which subphyla 27.

(a) Cephalochordata

(c) Urochordata

(a) Arthropoda

(c) Mammals

(b) Cyclostomata

(d) Fishes

28. All chordates at one or the other stage possess

[MP PMT 2004]

- (a) Vertebral column
- (b) Pharyngeal gills-slits
- (c) Two pairs of pentadactyle limb
- (d) A movable jaw
- 29. Which one feature is common to Amphioxus, frog, sea horse and crocodile [AIEEE Pharmacy 2003]
 - (a) Pharyngeal gill slits, at least in the developmental stages
 - (b) A three-chambered heart
 - (c) Dorsal solid nerve chord
 - (d) Skeleton formed of cartilage and bones
- 30. Larva of Balanoglossus is
 - (a) Tornaria
- (b) Muller's larva
- (c) Kentrogen larva
- (d) Tadpole
- 31. Which of the following is a distinct character [Wardha 2005]
 - (a) Chorda dorsalis
- (b) Cephalization
- (c) Claws
- (d) Pharyngotomy
- 32. Vertebral column is derived from
 - (a) Notochord
- (b) Dorsal nerve cord
- (c) Ventral nerve cord
- (d) Outgrowth of cranium
- 33. Match items in column I with those give in column II

m	Column I	THE RESERVE	Column II
(A)	Limbless reptile	(i)	Lamprey
(B)	Jawless vertebrate	(ii)	Salamander
(C)	Amphibian	(iii)	Snake
(D)	Cartilaginous fish	(iv)	Shark
(E)	Flightless bird	(v)	Ostrich

[Kerala CET 2005]

- (a) (A) (i), (B) (ii), (C) (iii), (D) (iv), (E) (v)
- (b) (A) (ii), (B) (i), (C) (iii), (D) (iv), (E) (v)
- (c) (A) (iii), (B) (i), (C) (ii), (D) (iv), (E) (v)
- (d) (A) (v), (B) (ii), (C) (iii), (D) (iv), (E) (i)
- 34. Common characteristic of all vertebrates without exception is [CBSE PMT 1994]
 - (a) Exoskeleton
 - (b) Presence of well developed skull
 - (c) Two pairs of functional apendages
 - (d) Division of body into head, neck, trunk and tail
- Which of the following is the smallest taxonomic group of animals having a cranium, vertebral column, ventral heart, pulmonary respiration and two pairs of limbs [AFMC 1998]
 - (a) Gnathostomata
- (b) Tetrapoda
- (c) Vertebrata
- (d) Chordata
- 36. The vertebrate does not have
- [Odisha JEE 2011]

[BHU 1993]

- (a) Epidermal scale
- (b) Claw
- (c) Tail
- (d) Cnidoblast
- 37. Ancestors of cyclostomes are
 - (b) Arthropods
 - (a) Myxinoides(c) Ostracoderms
- (d) Urochordates

 See the following diagram and identify the name of the animal and the phylum to which it belong correctly [NCERT]

- (a) Nereis, Annelida
- (b) Balanoglossus, Urochordata
- (c) Balanoglossus, Cephalochordata
- (d) Balanoglossus, Hemichordata
- 39. Birds and mammals have

[NCERT; MH CET 2000]

- (a) Three chambered heart
- (b) Four chambered heart
- (c) Six chambered heart
- (d) None of the above
- 40. Homeothermic animals is [MH CET 2000]
 - (a) Toad
- (b) Lizard
- (c) Rabbit
- (d) Frog
- 1. Which of the following are Anamniotes [RPMT 2001]
 - (a) Chondrichthyes, Osteichthyes, Amphibia
 - (b) Reptilia, Aves, Amphibia
 - (c) Amphibia, Aves, Mammals
 - (d) Reptilia, Mammals, Aves
- 42. In Urochordata notochord is found in
- in [RPMT 2001]
 - (a) Head of adult
- (b) Tail of adult
- (c) Tail of larva
- (d) Test of adult
- 3. In which of the following notochord is absent [RPMT 2001]
 - (a) Adult Herdmania and Balanoglossus
 - (b) Adult Herdmania and adult Branchiostoma
 - (c) Larva of Herdmania and Branchiostoma
 - (d) Larva of Herdmania and Balanoglossus
- 44. The correct classification of Balanoglossus is [RPMT 2001]
 - (a) Chordata → Vertebrata → Enteropneusta
 - (b) Chordata → Vertebrata → Pterobranchia
 - (c) Chordata → Hemichordata → Pterobranchia
 - (d) Chordata → Hemichordata → Enteropneusta
- In which of the following the notochord is present in embryonic stage [CBSE PMT 2002]
 - (a) Vertebrates
- (b) Some chordates
- (c) All chordates
- (d) Non-chordates

Which of the following is not a character of Chordata

[NCERT; MH CET 2002; CPMT 2010]

- (a) Dorsal tubular nerve cord
- (b) Pharyngeal gill slits
- (c) Presence of notochord
- (d) Presence of spinal cord
- Which animal is "Non-chordate-protochordata" 47.

[RPMT 2002; CPMT 2010]

Or

Which of the following is a hemichordate [Odisha JEE 2010]

- (a) Herdmania
- (b) Balanoglossus
- (c) Branchiostoma
- (d) Botryllus
- Mode of feeding in tunicates is 48.

[EAMCET 2002]

- (a) Parasitic
- (b) Macrophagus
- (c) Ciliary filter
- (d) Myxotrophic
- Which one of the following statements is totally wrong about 49. the occurrence of notochord, while the other three are correct [NCERT; CBSE PMT (Mains) 2011]
 - (a) It is absent throughout life in humans from the very beginning
 - (b) It is present throughout life in Amphioxus
 - (c) It is present only in larval tail in Ascidians
 - (d) It is replaced by a vertebral column in adult frog
- 50. Match the following and select the correct option

A.	Cyclostomes	1.	Hemichordata
B.	Aves	2.	Urochordata
C.	Tunicates	3.	Agnatha
D.	Balanoglossus	4.	Pisces
E.	Osteichthyes	5.	Tetrapod

[Kerala PMT 2011]

- (a) A-1, B-2, C-3, D-4, E-5
- (b) A-2, B-3, C-4, D-1, E-5
- (c) A-3, B-5, C-2, D-1, E-4
- (d) A-3, B-1, C-5, D-2, E-4
- (e) A-5, B-3, C-2, D-1, E-4
- Echidna and Ornithorhynchus are the connecting links between [AIIMS 2009]
 - (a) Amphibians and aves
 - (b) Mammals and amphibians
 - (c) Reptiles and mammals
 - (d) Reptiles and amphibians

52. Column I contains larval stages and column II contains the groups to which they belong. Match them correctly and choose the right answer

	Column I		Column II
A.	Planula	1.	Annelida
B.	Tornaria	2.	Mollusca
C.	Trochophore	3.	Arthropoda

- Jaw of shark contains 57.
 - (a) Thecodont teeth
- (b) Acrodont teeth
- (c) Pleurodont teeth
- (d) None of these
- See the following figures and click the correct option with 58. their respective classes

- (a) A Osteichthyes, B Chondrichthyes, C Cyclostomata
- (b) A Osteichthyes, B Chondrichthyes, C Osteichthyes
- (c) A Osteichthyes, B Chondrichthyes, C Chondrichthyes
- (d) A-Cyclostomata, B-Chondrichthyes, C-Chondrichthyes
- See the following figures and select the right option with [NCERT] their respective classes

- (a) A Cartilage fish, B Hag fish
- (b) A Cartilage fish, B Cartilage fish
- (c) A Bony fish, B Cartilage fish
- (d) A Bony fish, B Bony fish

The marine fish among the following varieties is

[MHCET 2015]

- (a) Stromateus
- (b) Labeo
- (c) Cirrhina
- (d) Catla
- Among the following edible fishes which one is a marine fish having rich source of omega-3 fatty acids

[NEET (Phase-II) 2016]

- (a) Mackerel
- (b) Mystus (d) Mrigala
- (c) Mangur

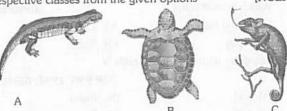

- [NEET (Phase-II) 2016]
- Choose the correct statement 62. (a) All pisces have gills covered by an operculum
 - (b) All mammals are viviparous
 - (c) All cyclostomes do not possess jaws and paired fins
 - (d) All reptiles have a three-chambered heart

Class-Amphibia

The pair of Amphibians found in Indian peninsula is 1.

[EAMCET 2009]

- (a) Amphiuma and Anguis
- (b) Tylototriton and Ichthyophis
- (c) Hyla and Ambystoma
- (d) Psittacus and Apteryx
- [EAMCET 2009] Ovoviviparity is seen in this caecilsian
 - (a) Wuchereria
- (b) Typhlonectus
- (c) Ichthyophis
- (d) Uraeotyphlus
- Select the correct order of classification of Rana tigrina upto 3. [Kerala PMT 2008]
 - (a) Chordata, craniata, amphibia, gnathostomata, rana
 - (b) Chordata, craniata, gnathostomata, amphibia, rana
 - (c) Chordata, amphibia, gnathostomata, craniata, tigrina
 - (d) Chordata, craniata, amphibia, gnathostomata, tigrina
 - (e) Gnathostomata, craniata, Chordata, rana, tigrina
- Which one of the following is not a true amphibian animal 4.
 - - (a) Frog
- (b) Tortoise
- (c) Salamander
- (d) Toad
- The common name of necturus is 5.
 - (a) Cave salamander
- (b) Congo eel
- (c) Hell bender
- (d) Mud puppy
- Salamander belongs to the class
- [J & K CET 2002]
 - (a) Reptilia
- (b) Amphibia
- (c) Aves
- (d) Mammalia
- Identify the names of the following animals with their 7. respective classes from the given options [NCERT]

- Salamandra, Urochordata; B -Chelone, (a) A -Cephalochordata; C - Chameleon, Hemichordata
- (b) A Salamandra, Amphibia; B Chelone, Amphibia; C - Chameleon, Amphibia
- A Salamandra, Reptilia; B Chelone, Reptilia; C - Chameleon, Reptilia
- (d) A Salamandra, Amphibia; B Chelone, Reptilia; C - Chameleon, Reptilia

Animal Kingdom 267 8. Ichthyophis belongs to [DPMT 2006] Retention of larval characters even after sexual maturity is 23. (a) Mammalia (b) Reptilia [BHU 1993; Kerala CET 2005] (c) Amphibia (d) Aves (a) Ontogenesis (b) Parthenogenesis Capacity of amphibians to change colour is called (c) Neoteny (d) Phyllogenesis (a) Metachrosis (b) Metachronous Axolotl larva belongs to the order 24. **[EAMCET 1994]** (c) Synchronous (d) None of these (a) Urodela (b) Anura The name of flying frog is [EAMCET 1998] (c) Apoda (d) Stegocephalia (a) Rhacophorus (b) Bufo Frog is [NCERT; CPMT 1994] (c) Phyllobates (d) Necturus (a) Aminotelic Frog which lives on the trees (b) Ammonotelic [NCERT; RPMT 1999] (c) Ureotelic (a) Alytes (d) Uricotelic (b) Bufo (c) Hyla (d) Rana Class-Reptilia 12. The functional kidney of frog tadpole is [CBSE PMT 1995] Classification of reptilia is based on (a) Pronephros (b) Mesonephros (a) Scales (b) Type of brain (c) Metanephros (d) Archinephros (c) Vaccuties (d) None of these 13. Axolotl larva of Ambyostoma normally fails 2. Typhlop is a metamorphose due to [KCET 1994; AFMC 2006] [BHU 2001] (a) True snake (b) False snake (a) Lack of Ca and Mg ions in water (c) True worm (d) Shark (b) Absence of phosphorus in water Only poisonous lizard of the world is 3. (c) Lack of iodine in water or diet [AMU (Med.) 2006; AFMC 2009] (d) High concentration of iodine in body (a) Draco (b) Heloderma Which of the following is a limbless amphibian (c) Sphenodon (d) Varanus [NCERT; MP PMT 1993, 2002; Kerala CET 2002; Venom of which of the following snakes is proteolytic 4. 	[HP PMT 2005]		(c) Cornified cells (d) Stratum germinativum
	(a) Reptiles (b) Amphibians (c) Mammals (d) Birds	29.	Pear-shaped head, sharply separated from rest of the body and coverd with small scales is a feature of
10	(c) Mammals (d) Birds Whose skin colour does not change [MP PMT 1995]		
16.	(a) Chameleon (b) Horse		
	(c) Garden lizard (d) Two of the above		
17.	Which of the following feature is not common between Newt	30.	Large size scales fully extended from side to side on the bell are characteristics of
17.	& Hemidactylus [CPMT 2005, 09]		(a) Krait and sea snake (b) Cobra and python
	(a) Body is divisible into head, neck, trunk and tail		(c) Rat snake and Cobra (d) Python and Krait
	(b) Head with pair of eyes and tympanic membrane	21	
	(c) Trunk has 2 pairs of limb for locomotion	31.	(a) Freshwater (b) Sea water
	(d) Heart is 3-chambered		
18.	Which type of respiratory organs are present in spiders and	0.0	The state of the s
	scorpions [AFMC 2006]	32.	Name a nonpoisonous snake
	(a) Book lungs (b) Gills		(a) Cobra (b) Krait (c) Viper (d) Rat snake
	(c) Gill books (d) Lungs	00	(-)
19.	Which one of the following is a matching pair of an animal and its a one of the characteristics [AIEEE Pharmacy 2004]	33.	
	(a) Chamaelon - binocular vision		
		0.4	
	(b) Heloderma - poison gland	34.	
	(c) Varanus - prehensile tail		(a) Bats (b) Crocodiles
	(d) House lizard- 4 chambered heart		(c) Turtles and pangolin (d) Lizards and snakes
20.	Some reptiles show autotomy which means	35.	
	(a) Voluntary breaking tail to confuse enemy		(a) Only sea snakes are non-poisonous
	(b) Signal for charging		(b) Only sea snakes are poisonous
	(c) Signal for courtship		(c) All water snakes are poisonous
	(d) State of starvation prior to death		(d) All sea snakes are poisonous
21.	Which among these is not a homoiotherm	36.	
	[Kerala PMT 2012]		(a) Birds (b) Crocodiles
	(a) Aptenodytes (b) Testudo		(c) Fishes (d) Toads
	(c) Delphinus (d) Neophron	37.	
	(e) Ornithorhynchus		(a) Cobra (b) Krait
22.	The truly land animals are [J & K CET 2010]	20	(c) Rattle snake (d) Python
	(a) Newts (b) Lung-fishes	38.	In suborder ophidia, the vertebrae are [EAMCET 1998; BHU 1999]
	(c) Salamanders (d) Calotes		(a) Amphicoelus (b) Acoelus
23.	The injection of serum of horse which has been repeatedly		(c) Heterocoelus (d) Procoelus
	injected by cobra venom into a person bitten by cobra results in	39.	
	(a) No immunity (b) Natural immunity		(a) Africa (b) America

Animal Kingdom 269 UNIVERSAL BOOK DEED

-			BOOK DEPOS 1350
40.	When the tail is cylindrical and ventral scales do not extend the entire width of the belly, the snake is [BHU 1994]	55.	Antivenin injections used for snake bite are prepared at [BCECE 2001]
	(a) Non-poisonous		(a) IVRI, Bareilly
	(b) Either poisonous or non-poisonous		(b) NDRI, Karnal
	(c) Definitely poisonous		(c) Haffkin's Research Institute, Mumbai
	(d) Deadly poisonous		(d) IARI, New Delhi
41.	Cleidoic eggs are found in [BHU 1994]	56.	
	(a) Fishes (b) Amphibia		of cobra [AFMC 2001]
	(c) Reptiles (d) None of these		(a) Digestive (b) Nervous
42.	Even ventricles of reptiles are partitioned but there is mixing		(c) Excretory (d) Circulatory
	of blood [AIIMS 1996]	57.	
	(a) Due to common ejection and entrance of blood in lungs		(a) Pisces (b) Reptiles
	(b) Auricles are non-partitioned		(c) Molluscans (d) Arthropods
	(c) Heart is partially four-chambered	58.	
	(d) None of these		(a) Acrodont (b) Bunodont
43.	Calotes versicolor is a [Odisha JEE 1997]		(c) Pleurodont (d) Thecodont
	(a) House lizard (b) Garden lizard	59.	
	(c) Flying lizard (d) Rock lizard		(a) Naja naja (b) Bungarus coerulus
44.	Animal which can move the upper jaw [Kerala PMT 1997]		(c) Naja hunnah (d) Vipera russelli
	(a) Elephant (b) Crocodile	60.	Which of the following is incorrectly matched
	(c) Clarius (d) Frog		[Odisha JEE 2010]
45.	(-)5		(a) Spiny tailed lizard- Hardwickii
			(b) Garden lizard- Hemidactylus flaviviridis
			(c) Gila monster - Heloderma
46.			(d) Monitor lizard - Varanus
40.	Typhlops is [BHU 2001]	61.	The characteristics of class Reptilia are
	(a) Sea snake (b) Grass snake		[NCERT; NEET (Karnataka) 2013]
47	(c) Glass snake (d) Blind snake		(a) Body covered with moist skin which is devoid of scales,
47.	The snake having head shield and elongated hexagonal vertebrals is [EAMCET 2000]		the ear is represented by a tympanum, alimentary
	(a) Naja (b) Eryx (c) Bungarus (d) Ptvas		canal, urinary and reproductive tracts open into a common cloaca
48.	(c) Bungarus (d) Ptyas Which of the following is a poisonous snake		(b) Fresh water animals with bony endoskeleton, air-
	[CBSE PMT 2000]		bladder to regulate buoyancy
	(a) Eryx (b) Natrix		(c) Marine animals with cartilaginous endoskeleton, body
	(c) Tree snake (d) Russel's viper		covered with placoid scales
49.	Which of the following snake has hind legs [CPMT 2000]		(d) Body covered with dry and cornified skin, scales over
	(a) Python (b) Bungarus		the body are epidermal, they do not have external ears
		No. of Concession,	Class-Aves
50.		MALE IN	
50.	The reptile which lacks penis belongs to [EAMCET 2000] (a) Ophidia (b) Crocodilia	1.	Characteristic features such as four-chambered heart,
	25-51 - J. 174 - SA SA SA J.		feather and pneumatic bone is applicable to the class of
51.	(c) Gymnophiona (d) Rhynchocephalia		vertebrate [NCERT; Odisha JEE 2002]
31.	Snake has [MHCET 2000; Pb. PMT 2004]		(a) Cyclostomata (b) Aves
	(a) Movable eyelids (b) No eyelids	TOOP I	(c) Reptilia (d) Mammals
52.	(c) Immovable eyelids (d) Eyelids placed in pouches Most favourable land adaptation for reptile is	2.	Quill feathers at the base of quill wings are called [BHU 1999]
	[CBSE PMT 2001]		(a) Remiges (b) Barbules
	(a) Moist skin (b) Scales on body		(c) Coverts (d) Down feathers
	(c) Pulmonary respiration (d) None of these	3.	The pelvic girdle of birds is attached to a complex structure
53.	Post anal tail is present in (a) Cobra (b) Earth worm	0.	formed by the fusion of last thoracic, all lumbar and first five
	(c) Scorpion (d) Lower invertebrate		caudal vertebra. This structure is called
54.			[MP PMT 1993; AFMC 2005]
J-1.	Diapside skull is found in the following [MP PMT 2001]		(a) Synsacrum (b) Symphysis
	(a) Natrix, Draco and Turtle		(c) Synkaryon (d) Sympelvis
	(b) Crocodile, Turtle and Seymouria	4.	Penguin is found in [CBSE PMT 1990; BHU 1997]
	(c) Sphenodon, Crocodile and Viper		(a) Africa (b) Australia
	(d) Calotes, Cobra and Varanosaurus		(c) America (d) Antarctica

(c) Pavo, Psittacula

(d) Psittacula, Pavo

20.	The mammal which possesses both the reptiles and mammalian characters [DPMT 1993]	33.	The feet with two toes forming cloven hoof is seen in [Kerala PMT 2004]
	(a) Marsupials (b) Monotremes		(a) Horse (b) Zebra
	(c) Equus (d) Oryctolagus		(c) Rhinoceros (d) Elephant
21.	Kangaroo is a member of which order		(e) Sheep
	[RPMT 1995; MP PMT 2000]	34.	The zoological name of common hare found in northern
	(a) Monotremata (b) Marsupilia		India is [MP PMT 2001; CPMT 2004]
	(c) Prototheria (d) Insectivora		(a) Oryctolagus cuniculus (b) Lepus ruficaudatus
22.	Bat can travel with [AFMC 1997]		(c) Dasypus sexcinctus (d) Alactaga indica
	(a) Eyes open	35.	The following mammal lays eggs
	(b) Eyes plugged and ears open		[KCET 1998; J & K CET 2005]
	(c) Ears plugged and eyes open		(a) Porcupine (b) Platypus
	(d) Ears closed and eyes plugged		(c) Kangaroo (d) Koala
23.	Egg laying mammals are found in	36.	Double Vagina are found in [RPMT 1999]
20.			(a) Monotremata (b) Eutheria
	7.50		(c) Marsupials (d) All of the above
94		37.	Which of the following is not viviparous [HP PMT 2005;
24.	A fat called blubber could be obtained from		AIPMT (Cancelled) 2015]
	[Kerala PMT 2001]		(a) Mole (b) Platypus
	(a) Bat (b) Dolphin	0.0	(c) Kangaroo (d) Shrew
0.5	(c) Shark (d) Blue whale	38.	One of the following is a very unique feature of the mammalian body [BHU 2000; RPMT 2002;
25.	Identify the aquatic mammal(s) from the following		CBSE PMT 2004; KCET 2006; MP PMT 2012]
	(A) Balaenoptera (B) Equus		(a) Four chambered heart (b) Rib cage
	(C) Delphinus (D) Pterophus		(c) Homeothermy (d) Presence of diaphragm
	(E) Felis	39.	Select the correct set of animals of class-mammalia
	[Kerala PMT 2010]	0,	[Odisha PMT 2002]
	(a) (A) and (C) only (b) (B) and (D) only		(a) Lion, hippopotamus, penguin, bat
	(c) (E) only (d) (D) and (E) only		(b) Lion, bat, whale, ostrich
	(e) (B) and (E) only		(c) Hippopotamus, penguin, whale, kangaroo
26.	Which of the following four animals does not come under		(d) Whale, bat, kangaroo, hippopotamus
	the same order as the other three [BHU 2012]	40.	Which character is not same in aves and mammals
	(a) Rat (b) Squirrel		[RPMT 2002]
	(c) Porcupine (d) Rabbit		(a) Single systemic arch (b) Metanephric kidney
27.	Ruminants belongs to order [Manipal 2005]		(c) Seven cervical vertebrae (d) Homoiotherms
	(a) Proboscida (b) Artiodactyla	41.	All mammals [NCERT;
	(c) Marsupials (d) Edentata		AMU (Med.) 2002; Odisha JEE 2009]
28.	Pouch is seen in [J & K CET 2010]		(a) Give birth to live young
	(a) Platypus (b) Bat		(b) Have a thick coat of hair
	(c) Lemur (d) Marsupial		(c) Nourish their young with milk
29.	The biological name of 'domestic cat' is [MP PMT 1993]		(d) Have a uterus
	(a) Panthera domestica (b) Felis domestica	42.	Most animals domesticated by man belong to the order
	(c) Felis leo (d) Panthera indica		[BHU 2002]
30.	Which one of the following characters is not typical of the		(a) Carnivora (b) Rodentia
	class Mammalia [CBSE PMT 2005]	(8) (22)	(c) Ungulata (d) Lagomorpha
	(a) Thecodont dentition (b) Alveolar lungs	43.	Which of the following is prototherian [BHU 1999]
	(c) Ten pairs of cranial nerves(d) Seven cervical vertebrae		(a) Platypus (b) Macropus
31.	Which of the following structures is present characteristically		(c) Opposum (d) Bradypus
	only in mammalian brain [MP PMT 2004]	44.	Jaw suspension characteristic of mammals is [MP PMT 2002]
	(a) Corpus fibrosum (b) Corpus striatum		(a) Amphistylic (b) Craniostylic
	(c) Corpus luteum (d) Corpus callosum		(c) Autodiastylic (d) Hyostylic
32.		45.	When embryo develops in the body of female but it does
J &	Flippers of seal are modified [AFMC 2004]		not obtain nutrients from the mother [RPMT 1999]
	(a) Fins (b) Hind limb		(a) Ovo-viviparous (b) Viviparous
	(c) Forelimb (d) Gills		(c) Oviparous (d) None of these

Identify the names of animals A, B and C

[NCERT]

- (a) Balaenopter, Macropus, Pteropus
- (b) Balaenoptera, Pteropus, Macropus
- (c) Macropus, Balaenoptera, Pteropus
- (d) Pteropus, Balaenoptera, Macropus
- Which of the following is rightly matched [CPMT 1995]
 - (a) Mammalia-Human beings (b) Mollusca Centipede
 - (c) Pisces Silver fish
- (d) Echinoderm Echidna
- 48. Consider the following four statements (A-D) about certain desert animals such as kangaroo rat
 - (A) They have dark colour and high rate of reproduction and excrete solid urine
 - (B) They do not drink water, breathe at a slow rate to conserve water and have their body covered with thick
 - (C) They feed on dry seeds and do not require drinking water
 - (D) They excrete very concentrated urine and do not use water to regulate body temperature.

Which two of the above statements for such animals are true [CBSE PMT 2008]

- (a) C and A
- (b) C and D
- (c) A and B
- (d) B and C
- Considered the following four conditions (A D) and select the correct pair of them as adaptation to environment in desert lizards.

The conditions

- (A) Burrowing in soil to escape high temperature
- (B) Losing heat rapidly from the body during high temperature
- (C) Bask in sun when temperature is low
- (D) Insulating body due to thick fatty dermis

Options

[CBSE PMT (Pre.) 2011]

- (a) (A), (B)
- (b) (C), (D)
- (c) (A), (C)
- (d) (B), (D)
- 50. Which one of the following is categorised as a parasite in true sense [CBSE PMT (Pre.) 2011]
 - (a) The cuckoo (Koel) lays its egg in crow's nest
 - (b) The female Anopheles bites and sucks blood from humans
 - (c) Human foetus developing inside the uterus draws nourishment from the mother
 - (d) Head louse living on the human scalp as well as lying eggs on human hair

Which one of the following animals is correctly matched with its particular named taxonomic category

[NCERT; CBSE PMT (Pre.) 2011]

- (a) Housefly Musca, an order
- (b) Tiger Tigris, the species
- (c) Cuttlefish Mollusca, a class
- (d) Humans Primata, the family
- Pick the mammal with true placenta [KCET 2011]
 - (a) Kangaroo
- (b) Echidna
- (c) Platypus
- (d) Mongoose
- 53. Which of the following is not a mammalian character

[MHCET 20021

- (a) Hairy skin
- (b) Muscular diaphragm (c) 3-chamberd heart
 - (d) RBCs enucleated
- 54. Diaphragm is found in
- [MH CET 2001]
- (a) Crocodile
- (b) Kangaroo
- (c) Ostrich
- (d) Snake
- 55. Arboreal mammals have (a) Flying character
- [MH CET 2001] (b) Burrowing character
- (c) Climbing character
- (d) None of the above
- 56. Hairs occur in all mammals except those of
 - (a) Chiroptera
- (b) Rodentia
- (c) Cetacea The sweat gland are scanty in
 - (d) Primates
- (a) Elephant
- (b) Man
- (c) Rabbit
- (d) Polar bear
- 58. "Sea lion" belongs to
 - (a) Class Reptilia
- (b) Subclass Prototheria
- (c) Superclass Pisces 59. The Zoological name of 'Lion-tailed macaque' is
 - (d) Order Carnivora
 - (a) Macaca rhesus
- (b) Macaca silenus (d) None of these
- (c) Macaca mulatta Locomotion in Kangaroo is
 - (a) Saltatorial
- (c) Cursorial
- (b) Volant
- Pinna is absent in
- (d) Creeping
- (a) Sirenia
- (c) Rodentia
- (b) Primates
- (d) All of these
- Which one has a poison gland 62. (a) Wall lizard
- (b) Scoliodon
- (c) Rat snake (d) Male platypus In mammals, few vertebrae join to form
 - [EAMCET 1995]
 - (a) Humerus
- (b) Femur
- (c) Synsacrum
- (d) Atlas
- 64. time because it possesses
- Whale is air breather but can live under water for a long [CPMT 1997]
 - (a) Large lungs
- (b) Small lungs
- (c) Blubber
- (d) Retea mirabile
- 65. Only poisonous mammal or monotreme mammal is [CBSE PMT 1992, 93; RPMT 1995; CPMT 1997;

- BCECE 1997; MP PMT 2002; WB JEE 2009]
- (c) Guinea pig
- (b) Echidna (d) Snake
- Which will not affect echolocation in bats
- [AFMC 1997]

[EAMCET 1994]

[RPMT 1995]

(a) Covering eyes only

(a) Ornithorhynchus

- (b) Covering the whole head
- (c) Covering the ears
- (d) Covering the eyes and ears

67.	Most primitive living mammals which provide an evidence of organic evolution from geographical distribution are found in [AIIMS 1998]	2.	Given below are types of cells present in some animals. Each one is specialized to perform a single specific function except [NCERT]
	(a) Africa (b) Australia		(a) Choanocytes (b) Interstitial cells
	(c) China (d) India		
68.	The zoological name of lion is [MP PMT 2000]		
	(a) Felis leo (b) Panthera tigris (c) Panthera pardus (d) Panthera leo persica	3.	Which one of the following sets of animals share a four chambered heart [NCERT]
69.	Which of the following mammals lacks corpus callosum [MP PMT 2000]		(a) Amphibian, Reptiles, Birds
	(a) Macaca (b) Macropus		(b) Crocodiles, Birds, Mammals
	(c) Balaenoptera (d) Ornithorhynchus		(c) Crocodiles, Lizards, Turtles
70.	Vestigial pelvic girdle and bones of hind limbs are		
	characteristic of [HPMT 2000]		(d) Lizards, Mammals, Birds
	(a) Whales (b) Otters	4.	
	(c) Rodents (d) Sharks		skin [NCERT]
71.	Which of the following exist in maximum number of terms of genera and species [AFMC 2000]		(a) Snake and Frog (b) Chameleon and Turtle
	of genera and species [AFMC 2000] (a) Aquatic mammals (b) Carnivore mammals		(c) Frog and Pigeon (d) Crocodile and Tiger
	(c) Herbivore mammals (d) Terrestrial mammals	_	Birds and mammals share one of the following
72.		5.	
1710707	(a) Whale (b) Elephant		CHARACTERISTICS AND AN ADMINISTRATION OF THE PARTY OF THE
	(c) Camel (d) Dinosaur		(a) Pigmented skin
73.	Without teats, mammary glands are found in [EAMCET 1998;		(b) Alimentary canal with some modification
	BHU 2000; MHCET 2000; CBSE PMT 2001]		(c) Viviparity
	(a) Prototheria (b) Metatheria (c) Eutheria (d) Theria		(d) Warm blooded nature
74.	Bats belong to which order		
14.	[MP PMT 1994; CBSE PMT 2000; BVP 2001]	6.	
	(a) Carnivora (b) Chiroptera		single taxonomic group (order) [NCERT; AFMC 2012]
	(c) Dermoptera (d) Cetacea		(a) Cuttlefish, Jellyfish, Silverfish, Dogfish, Starfish
75.	A group of animals having marsupium [MP PMT 2001; CBSE PMT 2001; MHCET 2001; BVP 2001]		(b) Bat, Pigeon, Butterfly
	(a) Monotremata (b) Eutheria		(c) Monkey, Chimpanzee, Man, Gorilla
	(c) Metatheria (d) Prototheria		(d) Silkworm, Tapeworm, Earthworm
76.	Echidna is found in [BHU 2001]	7	
	(a) India (b) Africa (c) Malaysia (d) Australia	7.	
77.	(c) Malaysia (d) Australia Which one of the following is egg-laying mammal [RPMT 2001; MP PMT 2001]		 (a) Mesoglea is present in between ectoderm and endoderm in Obelia
	(a) Pangolin (b) Tachyglossus		(b) Radial symmetry is found in Asterias
	(c) Porcupine (d) Bat		(c) Fasciola is a pseudocoelomate animal
78.	Order primata contains [CPMT 2001]		
	(a) Shrew and hedge hog (b) Bats and vampire		(d) Taenia is a triploblastic animal
	(c) Monkeys and man (d) Horses and zebra The order insectivora comes under [KCET 2001]	8.	Which one of the following statements is incorrect [NCERT]
79.			(a) In cockroaches and prawns excretion of waste material
	(a) Class-mammalia (b) Class-insecta (c) Phylum-echinodermata (d) Phylum-arthropoda		occurs through malpighian tubules.
80.	Which of the following represents order of 'Horse' [NEET 2017]		(b) In ctenophors, locomotion is mediated by comb plates
	(a) Equidae (b) Perissodactyla		
	(c) Caballus (d) Ferus		
			(d) Earthworms are hermaphrodites and yet cross fertilization take place among them
	NCERT	9.	Which one of the following is oviparous [NCERT]
	Exemplar Questions		(a) Platypus (b) Flying fox (Bat)
1	In some animal groups, the body is found divided into		(c) Elephant (d) Whale
1.	compartments with at least some organs/organ repeated. This characteristic feature is named [NCERT]	10.	Which one of the following is not a poisonous snake [NCERT]
	(a) Segmentation (b) Metamerism		(a) Cobra (b) Viper
	(c) Metagenesis (d) Metamorphosis		(c) Python (d) Krait
	(c) Metagenesis (d) Metamorphics		NT/ C2#3157231

11. Match the following list of animals with their level of organization

Division of Labour

Animal

- A. Organ level
- Pheritima
- B. Cellular agregate level
- Fasciola
- C. Tissue level
- iii Spongilla
- D. Organ system level

ii-C,

ii-D,

iv Obelia

Choose the correct match showing division of labour with animal example [NCERT]

- (a) i-B,
- iv-A
- (b) i-B. ii-D.
- iii-D, iv-A
- (c) i-D, ii-A,
- iii-B, iv-C

iii-C,

- i-A,
- iii-C, iv-B
- 12. Body cavity is the cavity present between body wall and gut wall. In some animals the body cavity is not lined by mesoderm. Such animals are called [NCERT]
 - (a) Acoelomate
- (b) Pseudocoelomate
- (c) Coelomate
- (d) Haemocoelomate
- 13. Match the column A with column B and choose the correct option

Column A

Column B

- A. Porifera
- Canal system
- B. Aschelminthes
- Water-vascular system
- C. Annelida
- Muscular Pharynx Comb Plates
- D. Arthropoda
- iv. Jointed appendages v. Metameres
- E. Echinodermata

[NCERT]

- (a) A-ii, B-iii, C-v, D-iv, E-i
- (b) A-ii, B-v, C-iii, D-iv, E-i
- (c) A-i, B-iii, C-v, D-iv, E-ii
- (d) A-i, B-v, C-iii, D-iv, E-ii

Critical Thinking

Objective Questions

- Note the following:
 - A. It is a fresh water, metamerically segmented protostome
 - B. The clitellum is absent
 - C. It is unisexual
 - D. Its larval form is Trochophore
 - E. The nervous system is found in the epidermis

Which of the above is true of "paddle worm"

[EAMCET 2009]

- (a) A, B and E
- (b) B, C and E
- (c) B, C and D
- (d) C, D and E
- 2. Which of the following endoparasites of humans does show viviparity [AIPMT (Cancelled) 2015]
 - (a) Enterobius vermicularis
 - (b) Trichinella spiralis
 - (c) Ascaris lumbricoides
- (d) Ancylostoma duodenale

3. Match the following

	List-I	36	List-II
(A)	Green glands	(1)	Scolopendra
(B)	Amphids and phasmids	(II)	Respiratory organ
(C)	Ctenidia	(III)	Shell protein
(D)	Poison claw	(IV)	Excretory organs
(E)	Concholin	(V)	Sense organs

The	correct n	natch is		[EA	MCET 2009]
	Α	В	С	D	E
(a)	IV	V	II	1	III
(b)	I sold re	III	IV	V	II
(c)	II	IV	V	III	I
(d)	III	IV	V	I	I

Match list I with list II and choose the correction option

List I (Organism)

List II (Excretory structure)

Malpighian tubules

(A) Cockroach

(B)

- Nephridia (1) (2)
- (C) Earthworm

Clarias

- (3)Kidneys
- (D) Balanoglossus
- Flame cells (4)
- (E) Flatworm
- Proboscis bland (5)
 - [Kerala PMT 2009]
- (a) (A) (1), (B) (3), (C) (2), (D) (4), (E) (5)
- (b) (A) (3), (B) (1), (C) (2), (D) (5), (E) (4)
- (c) (A) (2), (B) (1), (C) (3), (D) (5), (E) (4)
- (d) (A) (2), (B) (1), (C) (5), (D) (3), (E) (4)
- (e) (A) (2), (B) (3), (C) (1), (D) (5), (E) (4)
- 5. Coelom is cavity found between
 - (a) Ectoderm and Endoderm (b) Mesoderm and Endoderm
 - (c) Body wall and ectoderm
 - (d) Mesoderm and body wall
- In Hydra, both pseudopodia and flagella occur in 6.
 - (a) Nutritive cells
- (b) Epithelio-muscular cells

[CPMT 1994]

- (c) Sensory cells
- (d) Gland cells
- 7. Common between trichocysts
- of Paramecium and
- nematocysts of Hydra is
 - (a) Attachment and defence (b) Defence only
 - (c) Sensitivity
- (d) Food capturing
- In Hydra, egestion of undigested food and excretion of nitrogenous wastes occur through [CBSE PMT 2001]
 - (a) Mouth and tentacles
- (b) Mouth and body wall
- (c) Mouth and mouth
- (d) Body wall and body wall
- The scientific name of Asian tiger mosquito [WB JEE 2009] (a) Aedes aegypti

9.

- (b) Aedes albopictus
- (c) Aedes taeniorhychus
- (d) Aedes albolineatus

10. Taenia saginata differs from Taenia solium in

[CBSE PMT 1990]

- (a) Absence of scolex hooks
- (b) Absence of scolex hooks and uterine branching
- (c) Absence of scolex hooks and presence of both male and female reproductive organs
- (d) Presence of scolex hooks
- 11. Correctly matched set of phylum, class and example is

[MP PMT 2009]

- (a) Protozoa Mastigophora Entamoeba
- (b) Mollusca Bivalvia Pinactada
- (c) Arthropoda Diplopoda Scolopendra
- (d) Chordata Cyclostomata Phrynosoma
- 12. Sites of first, second and third moulting of Ascaris larva are

[AIIMS 2002]

- (a) Soil, lung, intestine
- (b) Soil, alveoli, lung
- (c) Soil, intestine, lung
- (d) Liver, stomach, intestine
- 13. Match List I with List II and select the correct option

	List I		List II
A.	Protozoa	1.	Pennatula
B.	Aschelminthes	2.	Beroe
C.	Porifera	3.	Monocystis
D.	Ctenophora	4.	Wuchereria
E.	Cnidaria	5.	Cliona

[Kerala PMT 2008]

- (a) A-3, B-5, C-4, D-1, E-2
- (b) A-4, B-3, C-5, D-2, E-1
- (c) A-3, B-4, C-5, D-2, E-1
- (d) A-2, B-4, C-5, D-3, E-1
- (e) A-3, B-4, C-5, D-1, E-2
- 14. Dorsal vessel of Earthworm is [APMEE 1996; Pb. PMT 1999]
 - (a) Distribution
 - (b) Collecting
 - (c) Collecting in first thirteen segments and distributing in the rest
 - (d) Distributing in first thirteen segments and collecting in the rest
- 15. Blood glands of Pheretima take part in

[APMEE 2001]

- (a) Formation of red blood corpuscles
 - (b) Formation of phagocytes
 - (c) Maintenance of blood volume
 - (d) Maintenance of blood circulation
- 16. Read the following statements and select the correct option
 - A. Circulatory system in arthropods is of closed type
 - B. Parapodia in annelids help in swimming
 - C. Phylum Mollusca is the second largest animal phylum
 - D. Aschelminthes are dioecious

[NCERT; Kerala PMT 2012]

- (a) A and C alone are wrong
- (b) A alone is wrong
- (c) C alone is wrong
- (d) C and D alone are wrong
- (e) D alone is wrong

17. Weberian ossicles are found in

[AIIMS 1999]

- (a) Frogs
- (b) Snakes
- (c) Fishes
- (d) Birds
- Match the items in column I with column II and choose the correct option

Column I			Column II
(A)	Ascus	(1)	Spirulina
(B)	Basidium	(2)	Penicillium
(C)	Protista	(3)	Agaricus
(D)	Cyanobacteria	(4)	Euglena
(E)	Animalia	(5)	Sponges

[Kerala PMT 2009]

- (a) (A) (2), (B) (3), (C) (4), (D) (5), (E) (1)
- (b) (A) (1), (B) (2), (C) (3), (D) (5), (E) (4)
- (c) (A) (2), (B) (5), (C) (3), (D) (1), (E) (4)
- (d) (A) (1), (B) (2), (C) (3), (D) (4), (E) (5)
- (e) (A) (2), (B) (3), (C) (4), (D) (1), (E) (5)
- 19. Which of the following group of characters is present in all chordates in some or other stage in their life

O

Chordates differ from nonchordates in having

[Odisha JEE 2012]

- (a) Mammary glands, hair and gill slits
- (b) Notochord, gill slits and dorsal tubular nervous system
- (c) Notochord, scales and dorsal tubular nervous system
- (d) Gill slits, vertebral column and notochord
- What is true about Nereis, Scorpion, Cockroach and Silver fish [CBSE PMT 2007]
 - (a) They all have jointed paired appendages
 - (b) They all posses dorsal heart
 - (c) None of them is aquatic
 - (d) They all belong to the same phylum
- 21. Which of the following pairs are correctly matched

	Animals		Morphological features
(A)	Crocodile	-	4-Chambered heart
(B)	Sea Urchin	-	Parapodia
(C)	Obelia	-	Metagenesis
(D)	Lemur	_	Thecodont

[CBSE PMT 2007]

- (a) A, C and D
- (b) B, C and D
- (c) Only A and D
- (d) Only A and B
- Which one of the following is matching set of a phylum and its three examples [CBSE PMT 2006]
 - (a) Mollusca-Loligo, Teredo, Octopus
 - (b) Porifera-Spongilla, Euplectella, Pennatula
 - (c) Cnidaria-Bonellia, Physalia, Aurelia
 - (d) Platyhelminthes-Planaria, Schistosoma, Enterobius
- 23. Which is living fossil
- [NCERT; MP PMT 2000]
- (a) Coelacanth
- (b) Limulus
- (c) Sphenodon
- (d) All of these

24. The group 'amniota' includes

[EAMCET 1998; KCET 1999; Wardha 2005]

- (a) Birds and reptiles
- (b) Birds and mammals
- (c) Reptiles and mammals
- (d) Reptiles, birds and mammals
- 25. The animal group, where the adults are degenerated but larvae are well developed, is [CPMT 1999]
 - (a) Agnatha
- (b) Tunicates
- (c) Amphibians
- (d) Cephalo chordates
- 26. Which one of the following statements is incorrect

[CBSE PMT 2006]

- (a) In insects, circulating body fluids serve to distribute oxygen to tissues
- (b) The principle of countercurrent flow facilitates efficient respiration in gills of fishes
- (c) The residual air in lungs slightly decreases the efficiency of respiration in mammals
- (d) The presence of non-respiratory air sacs, increases the efficiency of respiration in birds
- 27. Which of the following statement is true [Kerala PMT 2006]
 - (a) All living members of class cyclostomata are parasites on some fishes
 - (b) There are about 2,000 species in the class osteichthyes
 - (c) Ciona belongs to the subphylum cephalochordata
 - (d) Arthropods are diplobastic animals
 - (e) Ascaris lumbricoides is a flat worm
- 28. Heterocercal tail is found in

[RPMT 2002]

- (a) Cartilaginous fishes
- (b) Bony fishes(d) Amphibians
- 29. Stenohaline fishes are represented by
 - y [MP PMT 2002]
- (a) Fresh water fishes only
 - (b) Marine fishes only
 - (c) Those which can tolerate a narrow range of salinity in water only
 - (d) Those which can tolerate a wide range of salinity in water
- 30. Fishes having swim bladder, which do not have direct communication with the exterior and where resorbent and secretory part is not sharply separated from one another are called as [MP PMT 2002]
 - (a) Physostomes
- (b) Physoclists
- (c) Euphysoclists
- (d) Paraphysoclists
- **31.** Which one of the following combination is generally recommended for composite fish farming in India

[MP PMT 2001]

- (a) Catla, Cyprinus, Clarias
- (b) Catla, Labeo, Cirrhinus
- (c) Cirrhinus, Cyprinus, Channa
- (d) Clarias, Chanos, Cyprinus
- 32. Which type of coelom is found in frog [RPMT 2001]
 - (a) Enterocoel
- (b) Schizocoel
- (c) Pseudocoel
- (d) Haemocoel

- 33. Which of the following statements are true / false
 - A. In Torpedo the electric organs are capable of generating strong electric shock to paralyze the prey
 - B. Bony fishes use pectoral, pelvic, dorsal, anal and caudal fins in swimming
 - C. Amphibian skin is moist and has thick scales
 - D. Birds are poikilothermous animals
 - E. The most unique mammalian characteristic is the presence of milk producing mammary glands by which the young ones are nourished

[Kerala PMT 2006; CBSE PMT 2014]

- (a) A, B and C are true; D, E are false
- (b) A, B and E are true; C and D are false
- (c) A, D and E are true; B and C are false
- (d) A, B and D are false; C and E are true
- (e) Only D is true; A, B, C and E are false
- 34. Which of the following snake is not poisonous

[AIIMS 2000; CPMT 2001]

- (a) Naja naja
- (b) Python
- (c) Bungarus
- (d) Hydrophis
- Limbless lizard is
- [MP PMT 2000]
 (b) Ophisaurus
- (a) Draco(c) Amblyrhynchus
- (d) Moloch
- 36. Reptiles share which of the following character with birds and mammals [Pb. PMT 2000; CBSE PMT 2002]
 - (a) Amnion
- (b) Diaphragm
- (c) Homeothermy
- (d) All of these
- In which of the following subclasses of reptiles, the skull has a solid roof [MP PMT 2002]
 - (a) Anapsida
- (b) Diapsida
- (c) Synapsida
- (d) Parapsida
- 38. Which of the following bird is viviparous
 - viviparous [RPMT 1999]
 - (a) Penguin
- (b) Humming bird
- (c) Albatross
- (d) None of these
- 39. Which of the following sets is of flightless birds

[NCERT; MHCET 2002; Kerala PMT 2010]

- (a) Penguin, Pecock, Fowl, Rhea, Kiwi, Moa, Ostrich
- (b) Emu, Penguin, Rhea, Kiwi, Moa, Cassowary, Ostrich
- (c) Albatros, Humming bird, Falcon, Hawk, Emu
- (d) Ostrich, Emu, Kiwi, Falcon, Albatros
- 40. Which is the common character between all the mammals

[BHU 1999]

[KCET 2007]

- (a) They are oviparous
- (b) They are herbivorous
- (c) They are carnivorous
- (d) They have seven cervical vertebrae
- 41. Find the odd example(a) Sea lily
- (b) Sea fan
- (c) Sea cucumber
- (d) Sea urchin
- 42. Annual migration does not occur in the case of

[CBSE PMT 2006]

- (a) Salamander
- (b) Arctic tern
- (c) Salmon
- (d) Siberian crane

40	20 . 1	11 1	11	Marcon & Co. Co.
43.	Match	the 1	Oll	priiwo

Column I			Column II
A.	Euplectella	1.	Sea pen .
B.	Physalia	2.	Pinworm
C.	Pennatula	3.	Venus flower basket
D.	Enterobius	4.	Midwife toad
E.	Alytes	5.	Portuguese man of war

[MP PMT 1994; BHU 2001; Kerala PMT 2007, 091

- (a) A-5, B-4, C-3, D-2, E-1
- (b) A-5, B-3, C-4, D-2, E-1
- (c) A-4, B-5, C-1, D-2, E-3
- (d) A-3, B-5, C-1, D-2, E-4
- (e) A-2, B-1, C-3, D-4, E-5
- During its life cycle, Fasciola hepatica (Liver Fluke) infects its intermediate host and primary host at the following larval [CBSE PMT 2003] stages respectively
 - (a) Redia and miracidium
 - (b) Cercaria and redia
 - (c) Metacercaria and cercaria
 - (d) Miracidium and metacercaria
- 45. Sea cows are aquatic mammals included under

[MP PMT 2001]

- (a) Lagomorpha
- (b) Pinnipedia
- (c) Cetacea
- (d) Sirenia
- 46. Given below are four matchings of an animal and its kind of respiratory organ
 - 1. Silver Fish trachea, 2. Scorpion book lung, 3. Sea squirt - pharyngeal gills, 4. Dolphin - skin [CBSE PMT 2003]
 - (a) 3 and 4
- (b) 1 and 4
- (c) 1, 2 and 3
- (d) 2 and 4
- Sycon belongs to a group of animals, which are best 47. described as [CBSE PMT 2003]
 - (a) Multicellular having tissue organization, but not body cavity
 - (b) Unicellular or acellular
 - (c) Multicellular without any tissue organization
 - (d) Multicellular with a gastrovascular system
- 48. The correct route through which Ascaris passes to complete its life cycle after infecting a fresh host is

[BHU 1999; MP PMT 2013]

- (a) Intestine \rightarrow Liver \rightarrow Heart \rightarrow Lung \rightarrow Pharynx \rightarrow Gullet → Stomach → Intestine
- (b) Outside → Intestine → Liver → Heart → Lung → Pharynx → Gullet → Intestine
- (c) Intestine \rightarrow Liver \rightarrow Heart \rightarrow Lung \rightarrow Pharynx \rightarrow Gullet → Stomach → Intestine → Outside → Intestine
- (d) Outside → Intestine → Liver → Heart → Lung → Pharynx → Gullet → Stomach → Intestine Outside
- Cockroach and earthworm have common type of

[Pb. PMT 2004]

- (a) Heart
- (b) Nerve cord
- (c) Nephridia
- (d) Spermathecae

- 50. Fertilization in earthworm is
- [RPMT 1999]

- (a) Cross fertilization
- (b) Mutual fertilization
- (c) Self fertilization
- (d) None of these
- Choose the correct combination of the following [CPMT 2000]
 - (a) Annelida and porifera-phyla
 - (b) Aves and chordata-classes
 - (c) Mollusca and hydrozoa-classes
 - (d) Oligochaeta and arthropoda-phyla
- 52. Maximum nutritional diversity is found in the group

[CBSE PMT (Pre.) 2012]

- (a) Fungi
- (b) Animalia
- (c) Monera
- (d) Plantae
- Phylum annelida resembles mollusca in embryonic features because both have [MP PMT 1999]
 - (a) Spiral cleavage and mesoderm formation
 - (b) Identical conspicuous segmentation in body, muscles and nervous system
 - (c) Meroblastic cleavage and ectoderm formation
 - (d) Special type of mouth parts
- The group that does not fit into this category [MP PMT 1993]
 - (a) Amphibia
- (b) Reptiles
- (c) Aves
- (d) Mammals
- 55. In bioluminesence storage, energy changes into [AFMC 2002]
 - (a) Light energy
- (b) Radiant energy
- (c) Chemical energy
- (d) Mechanical energy
- The main difference between Gymnophiona (Apoda) and Urodela is that Urodela
 - (a) Have two auricles and one ventricle
 - (b) Have smooth moist skin
 - (c) Have a cloaca
 - (d) Respire by lungs in the adult stage
- 57. Body cavity surrounding alimentary canal but it is not lined by cellular layer in which of the following [BHU 2003]
 - (a) Nematodes
- (b) Platyhelminthes
- (c) Annelids
- (d) Echinoderms
- Match the items in column I with column II and choose the 58. correct option

	Column I		Column II		
A.	Binary fission	1.	Algae		
B.	Zoospore	2.	Amoeba		
C.	Conidium	3.	Hydra		
D.	Budding	4.	Penicillium		
E.	Gemmules	5.	Sponge		

[Kerala PMT 2010]

- (a) A-1; B-4; C-5; D-3; E-2 (b) A-2; B-1; C-4; D-3; E-5
- (c) A-2; B-4; C-3; D-5; E-1 (d) A-1; B-4; C-3; D-2; E-5
- (e) A-4; B-1; C-3; D-5; E-2

UNIVERSAL BOOK DEPOT 1960

[NCERT]

59. In which one of the following the genus name, its two characters and its class/phylum are correctly matched

[NCERT; CBSE PMT (Pre.) 2011]

	Genus name	T	wo characters	Class/ Phylum
	Jet all real	(a)	Cnidoblasts	Wing Dynlor
(a)	Aurelia	(b)	Organ level of organization	Coelenterata
		(a)	Body segmented	
(b)	Ascaris	(b)	Males and females distinct	Annelida
(c)	Salamandra	(a)	A tympanum represents ear	A1-11-1-
(0)	Salamanara	(b)	Fertilization is external	Amphibia
(d)	Pteropus	(a)	Skin possesses hair	Manage
(u)	rieropus	(b)	Oviparous	Mammalia

- Sinking of zooplankton during the day and rising to the surface at night is an example of [AIIMS 2010]
 - (a) Circinal rhythm
- (b) Circadian rhythm
- (c) Tidal rhythm
- (d) None of these
- 61. Which one of the following is not correctly matched

[WB JEE 2011]

- (a) Sycon canal system
- (b) Star fish radial symmetry
- (c) Ascaris flame cell
- (d) Prawn haemocoel
- 62. Match the following and select the correct answer

Column I		Column II		
A.	Choanocytes	1.	Platyhelminthes	
B.	Cnidoblasts	2.	Ctenophora	
C.	Flame cells	3.	Porifera	
D.	Nephridia	4.	Coelenterata	
E.	Comb plates	5.	Annelida	

[Kerala PMT 2010]

- (a) A-2, B-1, C-4, D-5, E-3 (b) A-2, B-4, C-1, D-5, E-3
- (c) A-5, B-1, C-3, D-2, E-4 (d) A-3, B-4, C-1, D-5, E-2
- (e) A-3, B-1, C-4, D-5, E-2
- Which one of the following statements about all the four of Spongilla, Leech, Dolphin and Penguin is correct

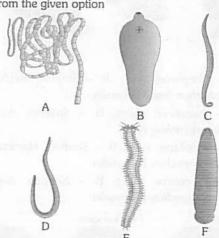

[CBSE PMT (Pre.) 2010]

- (a) All are bilaterally symmetrical
- (b) Penguin is homoiothermic while the remaining three are poikilothermic
- (c) Leech is a fresh water form while all others are marine
- (d) Spongilla has special collared cells called choanocytes, not found in the remaining three
- 64. Animals possess nerve networks or nervous systems to respond to their environment. But the single celled Amoeba does not possesses any nerve cell, so, how it come to know whether a particle it encounters is a grain or sand and not its dinner [AIIMS 2009]
 - (a) By chemotaxis
- (b) By skin
- (c) By hormones
- (d) All of these

65. Retractile claws are found in

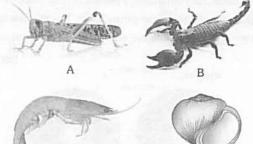

[MP PMT 2013]

- (a) Cat and Lion (c) Hyaena
- (b) Leopard
- (d) All of the above
- **66.** Identify the names of the following figure A, B, C, D, E and F from the given option

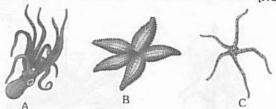

- (a) A Tape worm; B Liver fluke; C Male Roundworm;
 D Female Roundworm; E Nereis; F Hirudinaria
- (b) A Tape worm; B Liver fluke; C Female Roundworm;
 D Male Roundworm; E Nereis; F Hirudinaria
- (c) A Tape worm; B Liver fluke; C Male Roundworm;
 D Female Roundworm; E Hirudinaria; F Nereis
- (d) A Tape worm; B Liver fluke; C Female Roundworm;
 D Male Roundworm; E Hirudinaria; F Nereis

67. Identify the following figures correctly

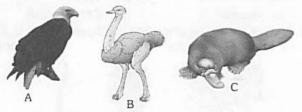

- (a) A Butterfly, B Scorpion, C Prawn, D Pila
- (b) A Locust, B Scorpion, C Prawn, D Snail
- (c) A Locust, B Prawn, C Scorpion, D Pila
- (d) A Locust, B Scorpion, C Prawn, D Pila
- 68. Identify the names of the following figure from the given option [NCERT]

- (a) A Ophiura, B Asterias, C Octopus
- (b) A Octopus, B Asterias, C Ophiura
- (c) A Octopus, B Asterias, C Ascidia
- (d) A Octopus, B Ascidia, C Ophiura

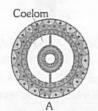

69. Identify the name of given animals with their respective classes [NCERT]

- (a) A Neophron, Aves, B Struthio, Reptilia; C Ornithorhynchus, Mammalia
- (b) A Neophron, Aves; B Struthio, Aves; C Ornithorhynchus, Aves
- (c) A Neophron, Aves; B Struthio, Mammalia; C Ornithorhynchus, Mammalia
- (d) A Neophron, Aves; B Struthio, Aves; C Ornithorhynchus, Mammalia

70.

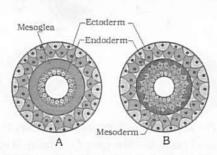

In which phylum A, B and C are found

[NCERT]

[NCERT]

- (a) Sponges, Aschelminthes, Platyhelminthes respectively
- (b) Aschelminthes, Platyhelminthes, Annelids respectively
- (c) Platyhelminthes, Annelids, Aschelminthes respectively
- (d) Annelids, Aschelminthes, Platyhelminthes respectively
- 71. The given figure shows the germs layer. The animals having structures shown in the figure are respectively known as

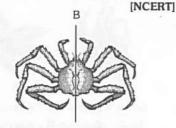

- (a) Triploblastic, Triploblastic(b) Diploblastic, Diploblastic
- (c) Triploblastic, Diploblastic (d) Diploblastic, Triploblastic
- 72. Identify the symmetry of animals A and B respectively

AR

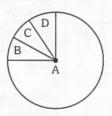

(c) Radial, Bilateral

- (b) Bilateral, Bilateral
- (d) Bilateral, Asymmetrical

- Select the Taxon mentioned that represents both marine and fresh water species [CBSE PMT 2014]
 - (a) Cephalochordata
- (b) Cnidaria
- (c) Echinoderms
- (d) Ctenophora
- 74. Given below is the representation of the extent of global diversity of invertebrates. What groups the four portions (A-D) represent repectively [CBSE PMT 2014]

Options

	Α	В	С	D
(a)	Molluscs	Other animal groups	Crustaceans	Insects
(b)	Insects	Molluscs	Crustaceans	Other animal Groups
(c)	Insects	Crustaceans	Other animal groups	Molluscs
(d)	Crustaceans	Insects	Molluscs	Other animal

75. Which of the following characteristics is mainly responsible for diversification of insects of land

[AIPMT (Cancelled) 2015]

- (a) Bilateral symmetry
- (b) Exoskeleton
- (c) Eyes
- (d) Segmentation
- 76. Which of the following characteristic features always holds true for the corresponding group of animals

[NEET (Phase-I) 2016]

		[IVEET (I mase-I) 2010
(a)	Cartilagious endoskeleton	Chondrichthyes
(b)	Viviparous	Mammalia
(c)	Possess a mouth with an upper and a lower jaw	Chordata
(d)	3 – chambered heart with one incompletely divided ventricle	Reptilia

- Which one of the following characteristics is not shared by birds and mammals [NEET (Phase-I) 2016]
 - (a) Ossified endoskeleton
- (b) Breathing using lungs
- (c) Viviparity
- (d) Warm blooded nature
- 78. Chitin is chemically a polymer of [Uttaranchal PMT 2001]

The chitinous exoskeleton of arthropods is formed by the polymerisation of [AIPMT 2015]

- (a) N-acetyl gluconic acid
- (b) N-acetyl glucosamine
- (c) N-acetyl muramic acid
- (d) None of these

UNIVERSAL BOOK DEPOT 1960

- Which of the following statements(s) is/are correct about Macropus spp [WB JEE 2016]
 - (a) They are metatherian mammals
 - (b) They are only found in Austria
 - (c) They have true placenta
 - (d) External ears are present
- An important characteristic that hemichordates share with Chordates is [NEET 2017]
 - (a) Absence of notochord(c) Pharynx with gill slits
- (b) Ventral tubular nerve cord
- (c) Pharynx with gill slits (d) Pharynx without gill slits

 81. Which among these is the correct combination of aquatic mammals [NEET 2017]
 - (a) Seals, Dolphins, Sharks (b) Dolphins, Seals, Trygon
 - (c) Whales, Dolphins, Seals (d) Trygon, Whales, Seals

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : Sponges have tissue level of organization.
- Reason : Sponges are multicellular.
- Assertion : In mollusca, circulatory system is of closed type.
 - Reason : The blood of mollusca contains haemoglobin [AIIMS 1995]
- 3. Assertion : Leucosolenia shows ascon type of canal
 - Reason : In Leucosolenia water passes through ostia

 → spongocoel → osculum.
- Assertion : Sponges do not show any animal nature.
 - Reason : Sponges are sessile with no apparent way of capturing food or eliminating water.
- 5. Assertion: The duck-billed *Platypus* and the spiny anteater, both are egg-laying animals yet they are grouped under mammals.
 - Reason : Both of them have seven cervical vertebrae and 12 pairs of cranial nerves. [AIIMS 2005]
- **6.** Assertion : Tapeworm, roundworm and pinworm are endoparasites of human intestine.
 - Reason : Improperly cooked food is the source of all intestinal infections. [AIIMS 2004, 08]
- Assertion : Coelenterates are known as Radiata.
 Reason : Coelenterates are bilaterally symmetrical.
- 8. Assertion: Hydra is green coloured.
 - Reason : Green colour is due to the presence of chlorophyll in their body wall.
- 9. Assertion : Nerve cells in coelenterata have complete co-ordination in their body.
 - Reason : True nerve cells occur for the first time in coelenterate.

- Assertion : King cobra is adaptive to oriental realm.
 - Reason : Wallace line prevents interaction of king cobra and kangaroo. [AIIMS 2009]
- 11. Assertion : Bats and whales are classified as mammals.
 - Reason : Bats and whales have four-chambered heart. [AIIMS 2003, 08]
- 12. Assertion : All birds, except the ones like koel (cuckoo) build nests for retiring and taking rest during night time (day time for nocturnal).
 - Reason : Koel lays its eggs in the nests of tailor bird.
- 13. Assertion : Obelia is dimorphic in nature.
 - Reason : Obelia shows polyp and gonangia form.
- 14. Assertion : Coelenterates show alternation of generation.
- Reason : In coelenterates, asexual generation is followed by sexual generation.
- 15. Assertion : Lateral line system is found in fishes and
- aquatic larval amphibians.

 Reason : Lateral line system has receptor of sensory
- cells derived from ectoderm. [AIIMS 2002]
- **16.** Assertion : *F.hepatica* undergoes both aerobic and anaerobic respiration.
- Reason : Fasciola respire only in absence of oxygen.
- **17.** Assertion : Plasmodium vivax is responsible for malaria.
 - Reason : Malaria is caused by polluted water.
 - [AIIMS 2001]
- 18. Assertion : Birds have one ovary.
 - Reason : This reduces the body weight for flight.
 - [AIIMS 1999]
- 19. Assertion : A shark can stay at a desired level in water without swimming.
 - Reason : It has a buoyancy-regulating organ called as the swim bladder. [AIIMS 1999]
- 20. Assertion : Sponges belong to Porifera.
 - Reason : Sponges have canal system. [AIIMS 1998]
- **21.** Assertion : There is no chance of malaria to a man on the bite of male *Anopheles* mosquito.
 - Reason : It carries a non-virulant strain of Plasmodium. [AIIMS 1998]
- 22. Assertion : Cold blooded animals do not have fat layer.
 - Reason : Cold blooded animals use their fat for
 - metabolic process during hibernation.
- [AIIMS 1997]
 23. Assertion : Acraniata is a group of organisms which do
 - not have distinct cranium.

 Reason: It includes small marine forms without head.
- [AIIMS 1997]
 24. Assertion : The skeleton of sponges is made up of
 - spicules.

 Reason : Composition of spicules help in
 - classification of sponges. [AIIMS 1995]

UNIVERSAL BOOK DEPOT 1960

282 Animal Kingdom

25.	Assertion	:	Cephalization is advantageous to an animal.	41.	Assertion	:	The fangs of snake is the maxillary teeth.
	Reason	:	It improves the appearance of the animal.		Reason	•	The poison apparatus in snake consists of poison gland, ducts and fangs.
	A		[AIIMS 1994]	42.	Assertion	:	In reptiles, hemipenes is present.
26.	Assertion Reason	:	Blood is colourless in the insects. Insect blood has no role in O_2 transport.		Reason	:	Hemipenes is the combination of both ovary and penis.
			[Alims 1994]	43.	Assertion	:	Parental care is seen in amphibians.
27.	Assertion	:	Lophodont dentition is also found in the mammals.		Reason	:	Amphibians have taken several method to protect their eggs and offspring.
	Reason	:	Lophodont type of dentition is specially for herbivore mammals.	44.	Assertion	:	In frogs, the entire skin serves a tangoreceptors.
28.	Assertion	:	'Calabar swelling' is caused by 'eye worm'.		Reason		Tactile organs and patches are presen
46	Reason	:	Loa loa is called the 'eye worm'.				throughout the skin of frog.
29.	Assertion	:	Metamerism is the characteristic of annelida.	45.	Assertion	:	"Lymph heart" is present in frog.
	Reason	:	Metamerism is one type of body		Reason	:	Lymph in frog is circulated by lymph heart.
30.	Assertion	:	segmentation. Blood is red in annelida.	46.	Assertion	:	In frog, most of the absorption takes place in intestine.
	Reason	:	RBCs are absent in them.		Reason	:	The intestine in frog is the coiled structure.
31.	Assertion	:	Baleen is an example of aquatic adaptaion.	47.	Assertion	:	Amphibians are poikilothermal.
	Reason	:	Baleen is a balloon like structure present beneath the skin of mammals.		Reason		Amphibians often undergoes summer sleep.
32.	Assertion		Spermathecae are the main part of	48.	Assertion		In fishes, heart is venous.
J	rissertion		reproductive system of annelida.		Reason		Only veins are present in the heart of fishes.
	Reason	:	Spermathecae help in sperm transfer.	49.	Assertion		Ampullae of lorenzini are found beneath
33.	Assertion		Coprophagy is the characteristic of mammal.				the skin of head region in fishes.
	Reason	:	Coprophagy is found in all mammals.		Reason	:	Ampullae of lorenzini acts as receptors.
34.	Assertion	:	Both true ribs and floating ribs are present in mammals.	50.	Assertion	:	Lateral line canal is one of the mair characteristics of fishes.
	Reason	:	By nature, sternal ribs are true ribs as, they possess all the characters of ribs.		Reason	;	Lateral line canal is a system of sense organ concerned with life in water.
35.	Assertion	:	Cutaneous glands help in regulation of body temperature.	51.	Assertion	:	Characters of cyclostomes show an advance over Amphioxus.
	Reason	:	Cutaneous glands are produced from stratum germinativum.		Reason	:	Cyclostomes have some degenerated characters.
36.	Assertion	:	Annelids are ureotelic.	52.	Assertion	:	Amphioxus has a simple organization
	Reason	:	Only excretory product of annelids is uric acid.		Reason		compared to vertebrates. Many important craniate structures are
37.	Assertion	:	Open circulatory system is found in most arthropods.	E 2			lacking in Amphioxus.
	Reason	:	Arthropods contain haemolymph which directly bathes internal tissues and organ.	53.	Assertion		Glochidium larva rapidly disperse to a great distance.
			[AIIMS 2010]	1868	Reason	:	Glochidium is parasitic on fish.
38.	Assertion	:	The birds can maintain a constant body temperature.	54.	Assertion	:	Respiration in <i>Amphioxus</i> is done by both water and blood.
	Reason	:	Birds possess feathers covering their body.		Reason	:	Amphioxus is aquatic and possesses blood.
39.	Assertion	:	Moulting or ecdysis occurs only in in-	55.	Assertion	:	Detorsion is the characteristic of mollusca.
	P-		vertebrates.		Reason	:	Detorison is an arrested stage of torsion.
	Reason		In birds, moulting usually takes an average time of six weeks.	56.	Assertion	:	Tube feet are characteristic organs of echinodermata.
40.	Assertion	:	Birds have no mammary gland.		Reason	:	Tube feet have an important role in
	Reason	:	Pigeons secrete 'pigeon's millk'.				respiration.

Assertion Endostyle is present at the pharyngeal groove of the midventral wall of the pharynx of Amphioxus. Reason Endostyle has an important role in respiration. 58. Assertion Herdmania has digestion mechanism like higher group of animals. Reason Liver of Herdmania possess several enzymes required for digestion. 59. Assertion In Balanoglossus notochord is replaced by pygochord. Pygochord supports adbominal region. Reason 60. Assertion Water vascular system is the characteristic of echinoderms. Reason Main function of water vascular system is locomotion. Assertion Balanoglossus is often considered as "acorn worms". Reason The word 'acorn worm' has no meaning.

Answers and Solutions

Important terms and classification of animals

- (a) Echinodermates and chordates are deuterostomous animals, in which blastopore of gastrula forms anus, so anus is formed earlier than mouth.
- 13. (b) The cell aggregate plan is seen in simplest animals, such as sponge. This plan exhibits essentially cluster of cells with rudimentary of labour amongst them.
- 18. (c) Blind sac body plan is found in coelenterates and flat worms. In this type of body plan animals has a single opening that act as both mouth and anus.
- 22. (a) From evolutionary point of view platyhelminthes are first triploblastic animals but do not contain coelom.
- 23. (b) Whole animal kingdom is classified into two sub-kingdom protozoa and metazoa. Unicellular animals are placed in protozoa while multicellular are included in metazoa.
- (c) All sponges are aquatic, mostly marine rarely fresh water (e. g. spongilla)
- 36. (d) True coelom is present in Annelid while platyhelminthes have pseudo (false) coelom called pseudocoelomate animals.
- 39. (a) In nemathelminthes or round worm, coelom is present but it is derived from blastocoel. It is not lined by peritoneum. This type of coelom is known as pseudocoelom.
- (a) Veliger, trochophore or glochidium larva are characterstic of mollusca.
- 44. (c) Metamerism is a condition in which the body is composed of a linear series of similar body segments called metameres or somites. It is found in Annelida, Arthropoda and chordata.

Phylum-Porifera

- 7. (b) Many pores are present on the body known as ostia through which water enters into the body. Ostia correspond to mouth of other animals.
- 8. (a) Choanocytes or collar cells are present only in sponges.
- (b) Sponges have a canal system and they need a continuous current of water flowing through their bodies for respiration, excretion, nutrition and reproduction.

- 12. (d) Food vacuole is transferred to amoebocytes and digestion is completed there.
- (d) In Leucosolenia, further development results in the formation of stereogastrula or parenchymula larva.
- 15. (b) Euplectella with its imprisoned shrimps makes a good wedding gift in Japan, symbolizing the idea "till death us do part".
- (a) Water currents produced by choanocytes because they are flagellated.
- 18. (b) Spongilla is known as fresh water sponge.
- 20. (a) The larva of cliona or boring sponge or sulphur sponges bores through and damages the skeleton of corals and shells of molluscs. It is harmful to pearl industry.
- 22. (b) Classification of sponges is primarily based on skeleton or spicules.
- **23.** (b) Amphiblastula and stereogastrula are the larval stages of sycon.
- 24. (d) When bathsponges are dried all its cells are destroyed except spongin fibre.
- 25. (c) Sponges have excellent regeneration power so each piece develop into complete individual.
- 26. (a) Archaeocytes may be converted into other types of cells and are also called undifferentiated totipotent cells.
- 27. (d) The spongin fibres are secreted by cells termed spongioblasts. They are formed of protein collen and occur as a network.
- 28. (b) In porifera, bodywall is with outer pinacoderm (ectoderm), inner choanoderm (endoderm) and gelatinous noncellular mesenchyme in between.
- (a) Food coming through the incoming water is ingested by choanocytes.
- 32. (a) The course taken by water into the canal system is.

 water from outside

 through dermal ostia

 through prosopyles radial canals

 through apopyles prosopyles outside.
- 34. (a) The gemmules are asexual reproductive bodies found in all fresh water and a few marine sponges. They are formed as internal buds and protect the species during unfavourable conditions.

- 35. (b) Spongin fibres occurs in various forms in the class Demospongiae. It may occur as a cement connecting together the siliceous spicules.
- **36.** (b) Digestion of food takes place partially in choanocytes and partially in wandering amoebocytes.
- 42. (a) Ascon is the simplest type of canal system, in which the body is thin-walled, bilaterally symmetrical and hollow due to the central cavity known as the spongocoel or gastrovascular cavity.
- 45. (a) Collar cells occur in sponges and located at the anterior end of each choanocyte.
- 47. (c) If carmine particles are placed close to osculum of a living sponge, these will be carried away.
- 49. (a) Sponges are multicellular grade organism.
- 50. (d) The sponges closely resemble to colonial choanoflagellates belonging to the phylum protozoa.
 Both possess collared and amoeboid cells.
- 53. (d) Sponges have numerous mouthlets(ostia) and one exit (osculum).
- 54. (b) Incurrent canals are communicated to outside through ostia but end blindly at their inner ends. Pinacocytes line these canals throughout.

Phylum-Coelenterata

- (a) Metagenesis is alternation of generations found in cnidaria phylum eg. Obelia
- (b) In class scyphozoa of phylum coelenterata, the polyp form is reduced or absent.
- 8. (b) Obelia shows alternation of asexual and sexual phase is (both phase are diploid). The asexual phase is represented by the colony while the sexual phase is medusa. The two alternate in life cycle. Such an alternation between asexual and sexual phases is called metagenesis.
- (c) Sea cucumber is the common name of Cucumaria. It is belong to phylum Echinodermata.

- 13. (d) The ctenophora is a small phylum of marine animals, which are commonly known as comb jellies or sea walnuts. The phylum takes its name from two Greek words, ketos = comb and phoros = bearing, as the animals possess eight comb like for locomotion. In Ctenophora, asexual reproduction is totally absent.
- 15. (a) Polyp and medusa are the asexual and sexual phase present respectively in coelenterates.
 Aurelia (jelly fish) belongs to class Scyphozoa, in which medusoid phase is dominant, polypoid phase absent.
- (b) Jelly-fishes (Aurelia) are the animals which belong to the class scyphozoa of the phylum coelenterata.
- 17. (d) Special type of cells called nematocytes are present in only coelenterata. These cells are used for food catching, defensive and offensive purposes.
- (a) Nematoblast (cnidoblast) are sensory in nature and acts as a organ for offense and defence.
- 20. (a) In Hydra the exchange of oxygen and CO₂ and the excretion of waste nitrogeneous matter (chiefly ammonia) occur directly by diffusion through cell membrane to outside.
- 22. (a) Body cavity of hydra is called coelenteron or gastrovascular cavity. It is surrounded by the body wall. The mouth leads into this cavity.
- (d) Pneumatophore is a gas filled chamber found in Physalia which helps in floating.
- 27. (d) Larval stage is absent in Hydra.
- 29. (c) Coelenterates are diploblastic animals i.e., derived only from two embryonic germ layers. Ectoderm and endoderm. They show radial symmetry.
- 32. (d) Sea pen are pen-like colonial coelenterates.
- (a) In hydrozoa, either only polyps are found or polyps and medusae are present. Examples – Hydra, Obelia, Physalia etc.
- 36. (c) Physalia is commonly known as 'portuguese man of war' due to sudden appearance and disappearance like active Navy ships of portugal which is pelagic, marine swimming animal.
- (d) Statocyst help to maintain equilibrium in larval stage (medusae) of Obelia.
- **38.** (c) Ephyra is a small, medusa like stage in the life cycle of scyphozoans or jelly fish (aurelia).
- 40. (a) Coelenterata (coelom + enteron) or phylum Cnidaria shows both sexual and asexual reproduction. The larval stage are Planula (Obelia) and Ephyra (Aurelia).
- 42. (d) Cnidoblasts (nematoblast) are specialised and modified interstitial cells which are found in coelenterate animals. The cnidoblasts are organs of defence and offence.
- 44. (c) Choanocytes cells is a characteristic feature of sponge which are also known as collar cells.
- **45.** (b) *Hydra* possesses a very primitive nervous system consisting of a synaptic network of bipolar and multipolar nerve cells. Thus, hydra has a nervous system but no brain.

- **46.** (a) Hydra has four types of nematocysts. They are penetrants (largest). Volents (smallest) steroline glutinant (small atriechous) and streptoline glutinants (large holotrichous)
- 50. (a) A unicellular green alga of the genus zoochlorellae and zooxanthallae habitually lives in nutritive-muscular cells of Hydra.
- **52.** (c) *Corallium rubrum* is the precious red coral of commerce. It is highly valued as it is used for making jewellery.
- **53.** (d) A sexually mature medusa of *obelia* bears four groups of gonads situated on the middle of four radial canal.
- **55.** (b) Stinging cells or cnidocytes having nematocysts which is found in ectoderm.
- **59.** (d) Nematocyst plays an important role in locomotion, food capture both offence and defence.
- **61.** (b) A mechanical stimulation of cnidocil by contact with an object is essential, but not sufficient, for discharge.
- (d) Gorgonia (sea-fan) is an animal. All animal lack cell wall.
- 64. (b) The hydra has a great power of regeneration, the power of replacing lost tissues. If a living hydra is cut into two or more very small fragments, every fragment develops into a new individual. Basal disc is developed towards lower side and mouth, hypostome and tentacles, developed at upper side in each part whatever is required according.
- **65.** (a) The interstitial cells become active and form germ cells by repeated multiplication which bulge out as gonads.
- (d) Cnidoblast or nematocysts are derived from interstitial cells of epidermis.
- **75.** (a) The medusa is strictly carnivorous. The food includes minute worms, nematods, insects, crustaceans, etc.
- **80.** (c) In this method of locomotion of *hydra*, usually the body first extends and then bends over, so that the tentacles attach to the substratum with the help of adhesive atrichous isorbizas.
- 82. (a) When the body can be divided into two similar halves by one or two vertical planes only, the radial symmetry is called biradial symmetry. It is present in the sea anemone.
- **86.** (b) Ctenophores have certain characteristics in common with the coelenterates, but there is no evidence that they were derived from the latter.
- 87. (d) During the development in Hydra, a solid gastrula is formed. The solid gastrula is neither ciliated nor free swimming because it is still attached to the parent body. This type of gastrula is characteristically called stereogastrula which represents the planula stage of hydrula.

Phylum-Platyhelminthes

- (a) Flame cell or solenocyte or protonephridia and nephridia are excretory organs of phylum platyhelminthes and annelida respectively.
- (a) Planaria (Dugesia) belong to class Turbellaria of phylum platyhelminthes. Mostly free living flatworms are placed in class Turbellaria.

- 3. (d) Self fertilization is fusion of male and female gametes (sex cells) produced by the same individual. Selffertilization occurs in bisexual organisms, including most flowering plants, numerous protozoans, and many invertebrates.
 - Flukes are hermaphrodites, meaning each worm has both ovaries and testes. Probably cross fertilization is the rule, but self fertilization is certainly a possibility. In any case, it means that every individual is capable of producing fertilized eggs, certainly an advantage in species in which a high reproductive output is required.
- 5. (b) In cestodes digestive system is completely absent due to endoparasitic mode of life but it may be present in Trematoda and Turbellaria.
- 6. (b) Schistosoma is blood fluke.
- 9. (b) Onchosphere, hexacanth and cysticercus (bladderworm) are different larval stage of *Taenia-solium*.
- 13. (d) Solenocytes are flame cells like structures attached within the body of nephridium. Each cell has nucleus, cytoplasm and long flagellum that runs through tubules.
- 14. (c) In Fasciola, laurer's canal is a temporary vaginal canal, which arise from oviduct during breeding season and act as fertilization tube.
- (d) Being parasitic in mode of life, locomotory organs are totally absent in *Taenia*.
- 18. (a) On the basis of body shape and habitat, platyhelminthes are classified into three classes. Turbellaria, Trematoda and cestoda.
- 20. (a) Among invertebrates upto platyhelminthes (flatworm), they have no coelom and are called acoelomate animals.
- 24. (d) Planaria/Dugesia is a free living leaf like flatworm found in fresh water. It has high power of regeneration so it is used in regeneration experiments.
- (b) Ventral surface of Dugesia's body is covered with fine hair like locomotory structure called cilia.
- 29. (d) Taenia Solium is a facultative anaerobe. It decomposes glycogen into CO₂ and fatty acids to liberate energy. However it is also capable of aerobic respiration and utilizes even traces of oxygen when available in host fluids.
- 30. (a) Platyhelminthes (liver-fluke) are first acoelomate animals, which have organ system organization and bilateral symmetry.
- 32. (a) Mehlis's glands of Tapeworm are associated with reproductive system. Secretory substance of mehlis's glands act as lubricant.
- 34. (b) Taenia has no digestive system, it obtain digested nutrients (like glucose, amino acid, glycerol) from small intestine of host through body surface with the help of microvilli.
- **36.** (b) Hexacanth embryo of *Taenia* is present in ripe proglottids or gravid proglottids, which is covered by shell structure, called onchosphere.
- 37. (a) Schistosoma lives in hepatic portal system and mesenteric blood vessels of human beings, so commonly called "blood fluke".

- **38.** (c) Fertilized egg of *Taenia solium* develops into an embryo that gets covered by a shell. The shelled embryos are called onchospheres. Secondary host acquires infection by ingesting the onchosphere, released from *Taenia*.
- 39. (b) Hymenolepis nana, belong to class cestoda and generally known as dwarf tapeworm, which length about 2-4.5 c.m. Life cycle of Hymenolepis is monogenetic.
- **40.** (a) Life history of liver fluke is digenetic, primary host is liver of sheep and secondary host is snail.
- **41.** (a) Schistosoma mansoni is the common human blood fluke. It belongs to class Trematoda of platyhelminthes. Blood fluke is digenetic, primary host is man and secondary host is snail.
- **42.** (a) Miracidium, sporocyst and cercaria are different form of larva in life history of schistosoma.
- **43.** (d) Mature proglottids are in the middle having reproductive organs both male and female.
- 45. (d) Shelled hexacanth larva in pig muscle, absorbs a large amount of watery fluid from host tissue and grows to a spherical pea sized, sac like cyst called bladder worm or cysticercus.
- **46.** (a) Mostly flatworms are included in class Turbellaria of phylum platyhelminthes e.g. planaria.
- 47. (a) Anus is absent in Fasciola hepatica. Undigested food material is probably ejected through the mouth or diffused into excretory system
- **49.** (b) Hexacanth moves in the body and ultimately settles in the muscles of secondary host (pig). Here it forms an encysted bladderworm or cysticercus. Cysticercus remain viable for upto six months.
- 50. (b) Different larval stage of liver fluke are found in following sequence.
 Miracidium → Sporocyst → Redia → Cercaria → Metacercaria
- **55.** (c) Taenia solium (Tape worm) and Echinococcus (Dog Tapeworm) are endoparasite. They obtain their food from host through body surface. So lacks alimentary canal.

Phylum-Nemathelminthes

- (d) Enterobius vermicularis is the human 'pin worm' or 'seat worm' and is perhaps the most common parasitic nematode of man throughout the world.
- (a) Pineal setae is the main characteristic of male Ascaris and situated on the dorsal side of cloaca.
- (d) Ascaris is monogenetic so it completes its life cycle in single host i.e., man.
- (a) Taenia is grouped into phylum platyhelminthes and is acoelomate.
- (c) Filariform larva of Ancylostoma infects a new host (man) by chance contact with his skin.
- (b) In Ascaris first moulting takes place in soil, second in intestine, third and fourth in lungs.
- (a) In Ascaris amphids are chemoreceptor which are present on ventrolateral lips.
- (c) Body cavity of Hookworm is pseudocoelom so it is called pseudocoelomate.

- 14. (b) Ascaris being an endoparasite respires anaerobically because the oxygen content in the hosts intestine is usually poor.
- **17.** (d) The adult *Wuchereria bancrofti* live in lymph vessel and lymph glands. It is a viviparous nematode.
- (b) Ascaris is monogenetic; its infection is through contaminated food and water.
- **23.** (a) The epidermis of Ascaris is syncytial (coenocytic) with scattered nuclei and with out partition wall.
- 24. (d) Male Ascaris is differentiable from female Ascaris tail end of male Ascaris is characterized by the presence of numerous genital papillae on ventral surface. There are 50 pairs of preanal papillae in front of cloaca, and 5 pairs of postanal papillae behind it. Sometimes, two chitinous spiculate process of equal size are seen protruding out of the cloacal aperture. These are called peneal setae or spicules which serve to transfer sperms into female vagina during copulation.
- 25. (d) In Ascaris, female is with straight posterior end of the body.
- 27. (c) Ascaris is monogenetic parasite; so there is no intermediate host only one host is required for the development.
- (c) Ascaris also secretes anti-enzyme and presence of, cuticle both protect it from hosts digestive enzymes.
- 30. (c) Ascariasis can be treated by antihelminthetic drugs such as Alcopar, Antipar, santonin, chenopodium oil and Tetrachloroethylene etc.
- (c) Dracunculus is digenetic, intermediate host is cyclops or water fleas.
- **33.** (b) Microfilariae are the larva of Wuchereria which are carried by Culex mosquito.
- 36. (c) Presence of the resistant thick cuticle is not degenerate but a specialized character with reference to parasitism.
- 38. (d) The sense organ of Ascaris are simple elevations supplied by nerve. They include various papillae, amphids and phasmids.
- 39. (a) The excretory pore (one) is situated midventrally, a little behind the mouth.
- (d) Pseudocoelom developes from blastoderm i.e., between mesoderm and endoderm of embryo.
- (d) Hookworm (Ancylostoma duodenale) live in the intestine of man and feed upon blood. No secondary host
- **46.** (b) Lifespan of Ascaris in the host is of 9-12 months.
- **47.** (a) Ascaris has three denticulate lips, one median dorsal and two venterolateral.
- **50.** (c) Microfilariae appear in peripheral blood circulation during night while day they disappear.
- 55. (b) Wuchereria is a ovoviviparous parasite which releases numerous juveniles called microfilariae.
- **56.** (b) The embryonated egg passes into the intestine of man and second stage larva hatches out from the egg.

Phylum Annelida

- 3. (d) Two male genital pores lie ventrolaterally in segment 18.
- (c) The annelids are triploblastic, i.e., having three germ layers-ectoderm, mesoderm and endoderm.
- (a) Species of monocystis are typically endoparasites of earthworms and occurs in their coelom and seminal vesicles.
- 6. (a) Pseudocoelom or false coelom is found in nematodes.
- 8. (b) Both annelids and arthropods possess ventral nerve cord.
- **14.** (c) Typhlosole is a highly glandular, vascular longitudinal ridge increasing the area for absorption of digested food.
- **15.** (c) Botryoidal tissue is found surrounding the alimentary canal of leech and is probably excretory in function.
- 17. (d) In 4, 5 and 6 segment red colour follicular bodies called blood glands serve for the manufacture of blood corpuscles and haemoglobin.
- 18. (b) Annelids like oligochaetes exhibit concentric "tube within a tube" body plan with multicellularity and bilateral symmetry.
- **19.** (a) Earthworm is brown or clay coloured. This is because of the pigment porphyrin.
- 20. (c) Prof. Karm Narayan Bahl of Lucknow University published a memoir on Indian earth worm *Pheretima* in 1926. He was awarded Joy Govind law memorial gold medal in 1942 for notable research in Asiatic Zoology.
- **22.** (b) One pair of ovary and 11 pairs of testis are found in Leech or *Hirudinea*.
- 24. (a) The Aphrodite is a marine polychaete which is commonly called the 'Sea mouse'. It belongs to the phylum Annelida.
- **29.** (a) Clitellar region contains 2000 nephridiopores per segment, so called "forest of nephridia".
- **30.** (c) Coelomic fluid of earthworm contains granulocytes, mucocytes, leucocytes and chloragogen cells.
- **32.** (c) In earthworm, two pairs of genital papillae are situated ventrally on 17th and 19th segments. It helps in copulation.
- **33.** (b) Flow of blood in dorsal blood vessel of earth worm is from posterior to anterior direction.
- **35.** (c) The single female genital pore is situated in the median position on 14th segments.
- (b) Hearts of Pheretima are situated in the segment 7, 9 (Lateral hearts) and 12, 13 (Lateral oesophageal hearts).
- 38. (d) In earthworm, fertilization is external and occurs in cocoon.
- 39. (a) During breeding season, glandular cells of clitellum become very active and secrete a slimy substance that forms a girdle like covering around the clitellum. In air, this gradually dries and hardens to form a tough but elastic, ring-like egg capsule or cocoon.
- 40. (b) Earthworms are monoecious or hermaphrodites but fertilization is crossed type due to protandrous condition.
- **42.** (c) Excretory products of earthworm are urea (about 50%), ammonia (about 40%) and traces of creatinin.
- **44.** (b) In pheretima posthuma, the clitellum occurs around the segments 14, 15 and 16.

- (c) Photoreceptors (with L shaped lens or optic organelles) of earthworm occurs on dorsal surface of the skin.
- 52. (b) In each of the segment 7, 9, 12 and 13 is found a pair of large, thick, muscular and rhythmically contractile hearts (Total 4 pairs).
- 56. (d) In earthworm, blood is red in colour, respiratory pigment haemoglobin is dissolved in the blood plasma.
- 57. (b) In leech, a triradiate mouth is found at its bottom. The mouth is used for puncturing the skin of the host. It is also suctorial.
- 58. (a) A larval stage is absent in earthworm, so their is no metamorphosis.
- 63. (b) The common Indian earthworm is pheretima posthuma.
- (d) Posterior sucker of Hirudinaria take part in locomotion and attachment.
- 67. (b) In earthworm, blood vascular system is different in first 13 segments as regards to number, arrangement and nature of blood vessels.
- 68. (d) Chloragogen cells are small star shaped, yellow cells concerned with storage of reserve food, deamination of proteins, formation of urea and also excretory.
- 74. (d) Nephridia are absent in the first three segments and the last segment. Some workers believe that all the nephridia are of micronephridia type. Other consider septal nephridia to be meganephridia.
- 76. (a) Trochophore larva is present during the development of archiannelida and polychaeta of the phylum annelida.
- **78.** (a) Four pairs of spermatheca are present in earthworm which are situated a pairs in the each 6th, 7th, 8th and 9th segments. They opens outside on intersegmental grove 5/6, 6/7, 7/8, 8/9.
- 79. (d) In between the 26th segment and the rectum intestine has a median dorsal fold projecting into the lumen. This is know as typhlosole.
- (a) Roof of pharynx contains pharyngeal glands containing chromophil cells secreting mucus and proteases.
- 81. (a) Septal nephridia are the only nephridia with nephrostome or funnel.
- (d) In earthworm, coelomic fluid works as a hydraulic skeleton, aids in locomotion.
- 86. (b) In earthworm, first segment or peristomium has a ventral mouth with a dorsal lobe or prostomium.
- (c) Neurons in earthrorm are motor, sensory and adjuster (association neurons).
- 93. (a) In dorsal blood vessel valves are present in front of septum in each segment.
- (b) Oxygen carrying blood pigment of earthworm is haemoglobin which is dissolved in blood plasma.
- (d) The coelomic fluid of earthworm is milky white without haemoglobin.
- 102. (a) Each photoreceptor cell of earthworm has a nucleus and the cytoplasm contains an optic organelle or L – shaped lens or phaosome made up of a hyaline substance.

- 105. (b) Pharyngeal nephridia of pheretima are situated in the segments, 4, 5 and 6. They opens in the anterior part of alimentary canal, i.e., buccal cavity and pharynx. They are without nephrostome.
- 109. (d) Locomotion in earthworm is carried with the help of buccal cavity, setae and the body muscles.

Phylum Arthropoda

- 4. (b) Metamorphosis is a conversitonal process in which small cockroach (nymph) convert into adult due to secretion of juvenile hormone.
- (c) Insecta is a another name of hexapoda, because they have 3 pair jointed legs on thoracic region.
- (c) Glow-worm and fireflies belong to the insect order coleoptera. Lampyris noctiluca is the common European glow-worm.
- (a) In cockroach, pigment sheath of ommatidia is non contractile so capable of only apposition or mosaic vision even during night.
- (c) Presence of jointed legs is unique character of phylum Arthropoda.
- **14.** (a) Arthropoda is largest phylum and includes about 80% of total animals. It includes about 9,00,000 species.
- (d) Malpighian body is related with kidney of higher chordates animals. It consist of glomerulus and bowman capsule.
- 17. (c) Mandibles are totally absent in the housefly (Musca).
- 22. (b) Tegra, sterna and pleura are joined by a flexible arthrodial membrane.
- 24. (c) In arachnids, respiration occurs through book lungs which are connected with the outside through spiracles or stigmeta.
- **26.** (d) The class insect has largest number of animals. It has about 7,75,000 species.
- 27. (d) Spider belongs to class arachnida.
- 30. (d) Most of the economically important species of phylum Arthropoda are found in class Insecta. It includes cockroach, bedbug, termites silkmoth, aphid, rat flea, wasp etc.
- **36.** (d) Haemolymph is found in insect blood which is colourless.
- **38.** (c) In some arthropodes like spiders, scorpions, mites, ticks etc., respiration occurs through book lungs or tracheae.
- 39. (c) The taste receptor (gustato receptors) are organs of taste, mainly confined to the tips of maxillary palps, labial palps labium and hypopharynx, in cockroach.
- (b) Xenopsylla cheopis, resembles the human flea and is the chief transmitter of bubonic plague.
- 42. (c) White ants are found in the tropical and warm temperate countries of the world, white ants are colonial, polymorphic and social insects.
- (d) Each compound eye of cockroach is composed of 2000 visual units called ommatidia.

- 45. (a) Malpighian tubules are the excretory organs of insects. It opens at the junction of midgut and hindgut (ileum) in cockroach. Malpighian tubules absorb excretory substances from haemolymph and fat bodies and pass into the proctodaum.
- 47. (b) The pupa of mosquito is known as tumbler. It has a life span of 2 7 days.
- 49. (d) Juvenile hormone is produced by corpora allata in insects. It favours the development of juvenile characteristics. During larval life, this hormone predominates and each moult yields another larger juvenile and keeps the larva in immature condition or maintains juvenility.
- 52. (b) In cockroach, an elongated, flat phalic gland or conglobate gland on the right side of ventral nerve cord and open out through a small pore close to male gonopore.
- (c) A larval stage occurs in housefly that lives in dung and is called maggot.
- 55. (a) In Pheretima septa are absent in first four segments and in between 9th and 10th segment.
- **58.** (d) After completion of metamorphosis housefly and mosquito will transform into an adult called 'Imago'.
- **59.** (a) The mosquito (*Culex*, *Anopheles*, and *Aedes*) are pathogenic. The fleas (*Culex*) is also pathogen *i.e.*, ectoparasites of birds and mammals, feeding on blood and the *tse-tse* fly is pathogen for sleeping sickness.
- **61.** (a) Moulting is controlled by a steroid hormone ecdysone produced by prothoracic glands.
- (c) Cockroach is omnivorous, feeds on all sorts organic debris.
- 63. (a) Johnston's organ lies in the second segment of antennae. In male mosquito, it helps to locate females by flight tone.
- 65. (b) In mosquito and housefly, halteres developes from metathorax. They are balancing organs during flight and also recieve sound stimuli.
- **69.** (a) In cockroach, a pair of many jointed structures are present on the tergite of 10th segment in both sexes, called anal cerci.
- (b) In mosquito, 5th instar larva changes into a pupa (nonfeeding), it is comma – shaped.
- (c) Different stages in the life history of housefly are Egg Larva (Maggot) – pupa – Imago (adult).
- (d) Corpora allata is attached to the brain. It is secrets juvenile horme (Prolongs larval period).
- 74. (a) Cockroach is unisexual and exhibit sexual dimorphism. In male's ninth segment bears a pair of anal styles ventrally.
- **75.** (d) Metamorphosis in cockroach is incomplete or paurometabolous type. Incomplete metamorphosis is also called gradual metamorphosis.
- 76. (d) If food material of housefly is solid, such as a sugar crystal, the fly first pours a little saliva or regurgitates droplets of liquid from its crop to liquify it and then sucks the liquid which fills the tubular pseudo-trachaeae by capillary action.
- **77.** (c) Metamorphosis of insects is controlled by a steroid hormone ecdyson produced by pro-thoracic.

- 79. (b) The total number of ganglia in ventral nerve cord of cockroach is nine pairs, i.e. three pairs thoracic and six pairs adbominal.
- 80. (d) In male anopheles, mandibles are totally absent because it is feed on nector and have only sucking mouth parts.
- **84.** (c) The major excretory product of insects is uric acid, so they are uricotelic.
- **88.** (c) Anopheles shows sexual dimorphism. Sex differentiation can be done on the basis of antennae and maxillary palps.
- 89. (b) In cockroach, the trachea is lived with spiral thickning of cuticle called intima which prevents the tracheal tubes from collapsing (Trachea of rabbits is also non collapsible).
- 92. (a) Cockroach has two pairs of wings. The first pair (mesothoracic) are thick, hard and leathery, protective in function called tegmina or elytra second pair (metathoracic) are thin, soft and membranous.
- 95. (d) Bed bug, sand fly, silk worm are placed in tracheate group of Arthropoda because they have trachae for respiration. Embryonic development of echinoderms shows a number of similarities with those of chordates.
- 97. (b) In female cockroach, abdomen is broader than in male.
- 98. (d) All body tissue receive oxygen directly through tracheoles.
- **100.** (a) In *periplaneta*, wings are well developed and in female of *Blatta*, the tegmina are very short, hind wing absent.
- 101. (a) The heart of cockroach is formed of 13 chambers each chamber (except the last one) has a pair of small lateral apertures called ostia which open into the pericardial sinus.
- 102. (d) Haploid parthenogenesis is called arrhenotoky. In it, development of egg into adult organism without fertilization. Example Honey bees, wasps and ants.
- 104. (c) The longest podomere or segment of cockroach is tibia.
- 106. (b) Housefly and butterfly possess larval stage. Their larval forms are maggot and caterpillar respectively.
- 107. (b) In butterfly, proboscis is long and is formed by galea of maxillae.
- **110.** (c) Locusts is herbivorous in diet and gregarious in nature, migrating or swarming in great number.
- **112.** (a) The labellae are traversed by a series of channels known pseudobracheae, because of their resemble once to tracheae in appearance.
- 113. (b) In cockroach, the tracheal system opens outside by ten pairs of spiracles. The first and third pairs spiracles remain open all the times.
- 114. (a) In insects, juvenile hormone or neotinin is produced by the corpora allata. It favours the development of juvenile characteristics. During larval life, this hormone predominates and each moult yield another larger juvenile.
- 116. (d) Antennae of cockroach bears tactile and olfactory receptors and are sensitive to touch and smell.
- 119. (c) Spider bears spinnerets or spinning organ just anterior to the terminal anus. These produce silken threads for construction of spider-web.

- (b) Ootheca of cockroach contains sixteen fertilized egg in two rows.
- **123.** (c) Ootheca of cockroach if formed of a protein secreted by collaterial gland.
- 125. (b) Palaemon is commonly called as prawn. It is an aquatic animal. It belongs to class crustacea of the phylum arthropoda.
- 127. (b) Sexual dimorphism is found in both Ascaris and cockroach.
- 128. (a) White ants are social and polymorphic insects, living in large, well organised colonies.
- 133. (a) Holometabolous or complete metamorphosis, includes four developmental stages – egg, larva, pupa and adult. Example – Lady Bird beetle (coccinella).
- 134. (c) Malpighian tubules of cockroach are concerned with homeostasis, osmoregulation and excretion. These are between 60 to 150 in number and are arranged in 6 – 8 bundles.
- 135. (b) Nephridia are absent in arthropoda.
- **136.** (b) *Peripatus* belong to onychophora. In *peripatus*, excretory organs are nephridia.
- 137. (b) In case of gradual metamorphosis, the newly hatched creature resembles an adult in general body form, but lacks wings and external genital appendages. It is also called paurometabolous development.
- 139. (b) Caterpillar of bombyx mori after 4 or 5 days, stops feeding and become inactive; Moulting or ecdysis then taken place. The larva repeats this process four times.
- 142. (a) Crustacean are the dominant arthropods of sea, with cephalothorax, biramous appendages, and respiration by gills. Common example are prawn, lobsters and crabs.
- 143. (d) Limulus or king crab belong to the sub class xiphosure and class merostomata of sub phylum chelicerata of phylum arthropoda. It is a living member of very ancient primitive chelicerates and hence called a "living fossil."
- 144. (c) Silver fish (Lepisma) is a primitive wingless insect without metamorphosis. It is belong to the phylum arthropoda.
- 145. (a) Caterpillar and maggot are the larva of respectively butterfly and housefly.
- 147. (b) Mouth parts of housefly are sponging type. These are adapted for sucking liquid or semiliquid.
- 148. (c) Tornaria larva is larva of Balanoglossus.
- 150. (b) The larva of mosquito is also known as 'wriggler'.
- 151. (d) The amount of yolk determine the type of cleavage in the egg. In superficial meroblastic cleavage, the cleavage remains restricted to the peripheral portion of the egg. This cleavage occur in arthropods especially insects.
- **153.** (b) Exoskeleton of arthropod is light weight, tough and composed of structural polysaccharide chitin.
- **155.** (b) In earthworm as well as cockroach, a ventral nerve cord extends back along the midventral axis from the sub pharyngeal ganglion.

- 157. (c) Abductor and adductor muscles associated with the mandibles move these in horizontal plane to cut and chew the food particles that are brought in between the mandibles by the first maxillae.
- 161. (a) In cockroach the food is grinded by mandibles and gizzard. In insects there is no oxygen transporting pigment and nitrogenous excretory product is uric acid.
- 162. (c) Cray fish (Astacus) is the phylum arthropoda.
- 163. (c) Leg of cockroach is five segmented, segments from base are-coxa, trochanter, femur, tibia and tarsus.
- 164. (c) In mosquito, metathoracic or hind wings are modified into halteres which are balancing and sound producing structures.
- 167. (b) Arthropoda have a compound eyes. Each compound eye is made of a large number of independent visual elements, called ommatidia. It helps in photoreception.
- 168. (a) The mouth parts of male mosquito are of sucking type while those of female mosquitoes are of piercing and sucking type.
- 169. (d) In cockroach, pigment sheath of ommatidia is non contractile so capable of only mosaic vision even during night.
- **170.** (c) Musca domestica shows a complete metamorphosis (holometabolous type).
- **171.** (d) Haemocoel is the body cavity of arthropods and molluscs, containing blood.
- **174** (a) Scorpion and ticks belong to the class arachnida of the phylum arthropoda.
- 181. (a) Pheromones are the secretion of small amount of chemical substance leading to specific physiological or behaviour responses in other members of the same species. Pheromones are also used to induce mating.
- 183. (b) In cockroach, newly hatched young one is called nymph. It resembles the adult in general structure but lacks the wings and mature reproductive organs.
- 195. (b) Class crustacea includes cyclops other options are from class insecta.

Phylum-Mollusca

- 4. (c) In sepia, the foot is modified into oral arms and siphon.
- 6. (a) Dentalium is commonly known as 'elephant's tusk-shell'.
- 7. (a) In bivalve molluscs (Unio) the gills are formed by fusion of successive branchial or gill filaments. These are surfaced with cilia. The beating of lateral cilia of gill filaments draw water into the infra branchial chamber of mantle cavity through the incurrent siphon. The water contain food material of Unio.
- (d) Decapoda is not a class of phylum mollusca. It is order of phylum Arthropoda.
- (c) Sea hare (Aplysia punctata) and snail (Helix) belong to same class gastropoda of phylum mollusca.
- 12. (c) Twisting of visceral mass in the snails through an angle of 180° due to which snails become asymmetrical.

- 13. (c) Neopilina is a most primitive mollusca having characters of annelida i.e., internal metameric segmentation, 5 pair of nephridia etc. There is no common name of this mollusc which is truly a living fossils and connecting link between annelids and molluscs.
- 17. (b) Cephalopoda word is composed of two words *cephalo* and *poda* which in Greek language means head and foot respectively *i.e.* foot present on head.
- 18. (d) The head of snail bears a pair of short, fleshy and stump-like optic stalk or ommatophores, one on either side behind 2nd pair of tentacles each ommatophore bears a small, black and some what circular eye, slightly below its tip on the other side.
- (c) Mantle secrets a calcareous shell which is generally external but may be internal an supportive or absent.
- **20.** (c) Snail moves with the creeping activity of the muscular sole of its foot.
- (c) Octopus belong to the class cephalopoda of phylum mollusca.
- **25.** (a) Mantle, foot and shell are characteristics of a mollusc. Out of the given options *Nautilus* is a mollusc, it is a tetrabranch cephalopod.
- **28.** (a) Loligo is a commonly known as "cuttle-fish". It is belong to phylum mollusca.
- 29. (b) Teredo is commonly known as 'shipworm'. It is a highly specialized marine bivalve which is very destructive to wood in sea water. The body is long and slender with a small anterior shell. The shell is used for burrowing in the wood of ships or wharves.
- 30. (a) Radula is found in gastropods.
- **31.** (c) In mollusca, blood has amoebocytes and often a copper containing blue respiratory pigment called haemocyanin.
- (b) Unio display filter-feeding that involves straining food from large quantities of water.
- **35.** (b) Snail may tide over long periods of drought by remaining torpid with the shell aperture tightly closed. It is then said to be in summer sleep or aestivation.
- (d) Octopus belongs to the class cephalopoda of phylum Mollusca.
- 37. (c) In mollusca, excretion occurs through paired sac like kidneys (or metanephridia) but in echinodermata kidneys are absent and excretion occurs partly by diffusion through body surface and partly by amoeboid coelomocytes.
- 39. (a) Shell is internal sepia, Loligo.
- (b) Ammonites belong to subclass ammonoidea of class cephalopoda. It is the largest subclass of extinct mesozoic cephalopods.
- 42. (d) Scaphopoda commonly called tusk shell, body within a tubular shell open at both ends.

Phylum-Echinodermata

 (d) Aristotle's lantern is a five teeth masticatory apparatus which is present surrounding to the mouth. It is used by sea urchin for feeding. Presence of Aristotles lantern is characteristic of class Echinoidea.

- 4. (d) Pedicellariae of Asterias are minute, whitish jaw like structure, found on both the body surface, in association with spine. It's help in the capture of prey and removal of debris.
- (c) The members of class crinoidea, are commonly called feather star or sea lilies because of their lily flower like appearance.
- (c) Star fish belong to class Asteroidea of phylum echinodermata.
- **10.** (b) In class ophiuroidea, Ambulacral grooves are absent or covered by ossicles.
- 12. (b) When irritated or when subjected to unfavorable conditions, many species of sea cucumbers cast out a part of their viscera by a strong muscular contraction that may either rupture the body wall or evert its contents through the anus or sometime mouth. The lost part regenerate again.
- **14.** (c) Echinoderms are exclusively marine most members are bottom dwellers or banthonic some are pelagic while a few are sedentary.
- **16.** (c) Adult echinodermata (Star fish) show pentamerouradial symmetry while larvae are show bilateral symmetry.
- 23. (d) Cephalization is a process of Brain formation. In echinodermata brain is absent, nervous system is consist only nerve ring and radial nerve cords.
- **24.** (d) Sea squid (*loligo*) belong to class cephalopoda of phylum mollusca.
- **27.** (a) Echinodermats are true enterocoelic animals, which is formed from enteron of gastrula like chordata.
- 28. (c) Tube feet act as locomotory organ in star fish.
- **30.** (a) Antedon belong to class crinoidea of phylum echinodermata. It is a living fossil and commonly known as feather star.
- 31. (a) Gorgonocephalus (Basket-star) belong to ophiuroidea. The body of Gorgonocephalus is consist of large pentagonal disc and five elongated and much branched arms
- 33. (d) Sea lilies are member of crinoidea having long stalk.
- 35. (d) Sea lily belong to class crinoidea of phylum echinodermata. Echinoderms possess both exoskeleton and endoskeleton. The endoskeleton consist of calcareous plates or ossicles while exoskeleton consist of spines and pedicellariae.

Phylum-Chordata

- 3. (d) The larva (tadpole) undergo retrogressive metamorphosis i.e., change from better developed larva to less developed adult e.g., Herdmania. The notochord is only present in the tail of larva and diasppear in adult.
- 5. (b) On the basis of presence or absence of jaw subphylum vertebrate is classified into Agnathostomata and Gnathostomata. In gnathostomata all that animals are included in which jaw is present.
- (c) In poikilothermal (cold blooded) animals, body temperature varies according to the temperature of the environment.

UNIVERSAL BOOK DEPOT 1960

- (b) Amphioxus (Branchiostoma) is placed in subphylum cephalopoda, in which notochord is present throughout life along entire length of the body.
- 9. (a) The blood vascular system in hemichordates is simple and open type. It includes a dorsal heart and two longitudinal vessels (one dorsal and one ventral). In chordates, closed circulatory system is found except in hemichordata or stomochordata (e.g., Herdmania) where, open circulatory system occurs.
- (c) This type of metamorphosis shows retrogression or degeneration from larva to adult.
- 12. (b) Both are included in class cyclostomata.
- (d) Homeothermic or warm blooded animals are able to maintain constant body temperature. e.g. Aves and Mammals.
- 22. (c) A post anal tail occurs in most chordates atleast in embryonic stage. In majority of the chordates it helps in balancing. Tail provides protection to genital and anal regions.
- 24. (d) Crocodile, Penguin, Whale and Dogfish all are chordates. So, all have gill slits at some stage of development.
- **25.** (b) In cyclostomata, body is eel shaped with scales jaw and lateral fins. Mouth rounded and suctorial. *e.g.* Petromyzon and myxine.
- 32. (a) In vertebrata, notochord is replaced partly or fully by a jointed vertebral column (back bone) i.e. vertebral column is derived from notochord.
- (b) Presence of well developed skull or cranium is important dignostic feature of chordata.
- 37. (c) Ostracoderms are earliest known primitive fish like extinct vertebrate. These along with cyclostomes constitute the Agnatha.
- 40. (c) Homeothermous animals are also known as warmblooded or endothermal animals. With constant body temperature, body heat is produced by the metabolic reaction taking place within the body. e.g. Aves and mammals.
- (a) In fishes and amphibian, amnion is absent and called Anamniota.
- (c) In urochordata, notochord and nerve cord is found only tail region in tadpole like larva.
- 45. (c) Notochord is the prime diagnostic feature of phylum chordata. Chordates possess notochord either throughout whole life or during early embryonic period.
- 48. (c) Tunicates are ciliary or filter feeder animals, which obtain their food from diatoms, desmids, protozoans and others pelagic microscopic organism, suspended in sea water, by the ciliary movement of wheel organ.

Class-Pisces

(a) Lateral line system is found in fishes. It serves to detect
waves in water current, thereby helps in swimming
process by perceiving the distance of surrounding
objects.

- (b) Elasmobranchii (dog fish) is an alternative name for cartilaginous fish or chondrichthyes. The name refers to the fact that the gill-slits are exposed and not covered by an operculum.
- (d) Torpedo (Astrope) is the electric ray. Their electric organs are highly modified masses of muscles cells.
- (d) Protopterus is the member of Dipnoi, which shows double breathing through gills as well as lungs.
- (a) Cyclostomes lack paired appendages.
 Aves have dry skin, without glands, only preen gland at base of tail present. Whale lack body hairs and hind limbs.
- (d) Sea horse (Hippocampus) has bony plates/scutes in addition to scales.
- 16. (a) Silver fish (Lepisma) is an arthropod.
- 17. (a) Dog fish or scoliodon is a true fish whereas silver fish, star fish and whale are arthropod, echinoderm, and mammal respectively. Catfish is a true fish. It has sensory barbels without scales.
- 19. (b) One auricle and one ventricle.
- 20. (c) Sea horse (Hippocampus) belongs to the class osteichthyes (due to bony skeleton) of super class pisces.
- (b) Pisces, amphibia and reptiles are unable to maintain constant body temperature hence, called poikilothermic or cold blooded animal.
- 22. (b) Fishes have two chambered heart one auricle and one ventricle, which receive only venous blood and pump it to gills for purification.
- 23. (a) Sea horse or hippocampus is a fish.
- 30. (b) Wallago attu is commonly known as catfish. It possess very small eyes and well developed sensory barbels by which they make a good vision and find their way.
- **33.** (b) *Hemicyclaspsis* is a genus of fossil, primitive, jawless fish like animals belonging to the class ostracodermi.
- 34. (b) Sucker fish attached to shark, feeds on the left over of shark's prey. The relationship is that of commensalism or ectocommensalism.
- (d) Whale-mammals, cuttlefish-cephalopod and silver fish-Insect.
- (a) Anadromous fishes move from sea to fresh water for breeding e.g. salmon.
- 39. (a) Anguilla is commonly known as freshwater eel. Eel is the name for a number of smooth snake like fishes with continuous dorsal anal and tail fins and without peluic fins. Anguilla anguilla the European eel is born in the Sargasso sea.
- 41. (b) Echeneis is commonly known as sucker fish. Its upper surface bears a large, flat oval adhesive disc or sucker. Sucker represents modified anterior dorsal fin.
- 42. (a) Claspers are intromittent organs found on the pelvic fins of male cartilaginous fishes like sharks. Sphyrna is commonly known as 'hammer-headed shark'.
- 47. (c) Lateral line system in a fish and some aquatic larvae (Tadpole) is made up of neuromast organs. It detects vibrations and pressure changes in water.
- (c) Latimeria is called living fossil as it has remained unchanged for several million years.
- 50. (a) Cartilagenous fishes belong to the class chondrichthyes due to cartilagenous endoskeleton of superclass pisces.

- (c) Anguilla sp (Eel) is a catadromous fish that lives in fresh water and breeds in sea.
- **53.** (d) All chondrichthyes possess cartilaginous endoskeleton without exception.
- **54.** (a) In class chondrichthyes males possess claspers on the plevic fins.
- (a) Mackerel is a marine fish having rich source of omega-3 fatty acids

Class-Amphibia

- 4. (b) Tortoise is a reptile belonging to the order chelonia.
- (d) Mud puppy is an aquatic salamander of genus Necturus with persistant gills. It is found in North America.
- (b) Salamander is a semiterrestrial lizard-like tailed carnivorous and nocturnal amphibian.
- (c) Ichthyophis is a limbless amphibian of 15-22 cm length that lives in burrows in moist soil.
- (a) Ability to change colour as in amphibians by expansion and contraction of pigment cells is called metachrosis.
- 10. (a) Rhacophorus has characteristic large webs developed between the much elongated digits. Webs and flattened body serve as a parachute in gliding from higher elevation to a lower ones, so they are designated 'flying frogs'.
- 11. (c) Hyla is also known as tree frog.
- 12. (a) The functional kidney of a frog tadpole is pronephros (head kidney) developed from nephrostomes in the anterior region.
- 13. (c) Environmental factors affect metamorphosis in several ways. Abundence of food, cold temperature or insufficient iodine (component of thyroxin hormone) may cause failure of metamorphosis and retention of larval features. Calcium, magnesium, phosphorus are not found to play any role in metamorphosis in animals. Larva of Ambystoma is known as axolotl. It is found in USA (North America) and Maxico. It show neoteny or paedogenesis.
- (b) Ichthyophis is a limbless amphibian showing parental care. It has no tongue.
- 16. (a) Pipa americana is commonly known as surinam toad.
- (d) Caecilians or limbless amphibians belong to the order Gymnophiona or Apoda. They are sometimes called blindworms.
- (d) Bombinator is a small sized amphibian found in Europe. It is commonly known as Fire-belied toad.
- (c) Frog is ureotelic because nitrogenous excretory product is usually urea.

Class-Reptilia

- (c) Classification of reptiles is based on temporal fossa (vaccuties) on skull.
- (a) Typhlopidae includes burrowing snakes having a vestigeal pelvic girdle and having reduced eyes covered by scales; found in almost all parts of the world except New Zealand.

- (b) Heloderma (Gila monster) is the only poisonous lizard in the world. It is also called 'Beaded lizard' because its scales resemble beads.
- (c) Reptiles have body temperature which varies with that
 of its surroundings and embryos have amnion, chorion
 and allantois.
- (d) Body of Tortoise is enclosed in two shell plates, dorsal carapace and ventral plastron.
- (a) Cobra is characterized by hood supported by ribs bearing spectacle mark dorsally. The third supralabial shield of upper lip touches eye and nasal shield.
- (c) Poison glands of snake are modified salivary glands (Superior labial or parotid glands).
- 14. (b) A snake has no middle ear. It perceives sound through skin from earth.
- **16.** (b) Colour changing power is present in pisces, amphibians and reptiles but absent in aves and mammals.
- 18. (a) In scorpion and spiders the respiratory organs are book lungs. They are named so because their folds resemble the leaves in a book. In this the exchange of gases takes place between the air of interlamelar spaces and the venous blood through the thin membranous walls of the lamellae.
- 20. (a) The tail of most lizard is easily broken off when threatened or seized by a predator. This ability is known as autotomy. Autotomy is voluntary breaking tail to confuse enemy.
- 24. (d) In poisonous snakes, two maxillary teeth are enlarged, grooved or tubular. They are called poison fangs and are concerned with injecting poison.
- **25.** (a) *Draco* is a lizard which glides with the help of patagium, it is called 'flying dragon'.
- **27.** (a) Two common marine poisonous snakes are *Enhydrina* and *Hydrophis*.
- **28.** (c) Snakes shed scaly epidermis of skin periodically usually in one piece. This process is termed moulting of ecdysis of cornified cells of skin.
- 29. (b) A viper can be easily identified by its triangular, pearshaped head bearing small cephalic scales.
- **31.** (a) Gavial or gharial, *Gavialis gangeticus* is found in freshwater. It lives in Gangas and Brahmputra rivers and grows to 8 metres.
- **36.** (b) The lung cavity of crocodile is separated from rest of the body cavity by a muscular diaphragm.
- **39.** (b) There are two species of *Heloderma*, *H. Suspectum* and *H. horridum*. Both are found in America.
- **41.** (c) Shelled eggs are found in reptiles and birds are known as cleidoic eggs.
- **43.** (b) Calotes versicolor is commonly known as Garden lizard. It is quite common in hedges, garden and jungles.
- 45. (b) Foramen of panizzae is a aperture in the heart of lizards and crocodiles. It is located at the point where right and left aortae cross each other and are in contact.
- **49.** (a) Python and Boa have vestigeal pelvic girdle and hind limbs.
- **50.** (d) In some reptiles, cloacle aperture is transverse and male is without copulatory sacs (Penis) *e.g. sphenodon*. They are includes in order Rhynchocephalia.

- (c) Eyelids of snake are immovable, nictiting membrane is absent.
- 52. (b) The loss of water from body is prevented by dry cornified scales on the body of reptiles. It is a favourable land adaptation.
- **55.** (c) In India, antivenin injections are prepared at Haffkin's Institute, mumbai and central Research Institute, Kausuali (Shimla).
- 56. (b) Poison of cobra is most virulent. It is a neurotoxin attacking nerve centres and causing paralysis of muscles, especially those of respiratory muscles.
- (d) Crocodile is a carnivorous and feeds on fish, aquatic birds and mammals. It has the codont teeth.

Class-Aves

- (c) Coverts are small feathers similar to quills meant for filling gaps on the wings and tail.
- (a) A synsacrum is formed by fusion of posterior thoracic, lumbar, sacral and anterior caudal vertebrae.
- (d) Penguin is a flightless bird occurs in flocks in the Antarctic region and some islands of south Africa.
- (a) The flightless bird cassowary occurs in N.E. Australia and New Guinea.
- (c) Presence of a single functional ovary of the left side in the female bird leads to reduction of weight which is so essential for flight.
- (a) Ratitae are the flightless birds which are grouped under super order paleognathae.
- (c) Archaeopteryx possessed prolonged jaws or beak. However, it contained teeth.
- (a) Heterocoelous is a term used to denote a vertebra whose centrum has one face convex and the other concave.
- (a) The syrinx or sound producing organ lies at or near the junction of trachea and bronchi.
- 20. (a) Huxley has called birds to be glorified reptiles.
- 25. (b) Birds are homoeothermal or capable of keeping their body temperature constant.
- 27. (b) Pigeon are noted for their unique ability to produce 'pigeon milk' by crop glands. It is formed by the degenration of the epithelial cells lining the crop. The milk is produced by both sexes.
- 29. (b) The clavicle and interclavicles are fused to form a v-shaped bone, called furcula or wishbone or merry thought bone which help in flying.
- (d) Birds have bipedal locomotion because fore limbs are modified into wings.
- (d) Egg of ostrich weights nearly 1.5 Kg. and requires about 50 minutes to boil it. It is the largest egg among the animals.
- (c) Bones of birds are pneumatic or hollow and have no bone marrow.
- 33. (b) In birds, only one gland is present in the skin at the base of short tail or uropygium. It is known as oil or preen gland.
- (c) Kiwi is the smallest living flightless bird. It is found in New Zealand.

Class-Mammalia

- (b) Prototherians are primitive, egg laying mammals, oviparous mammals, reptile like mammals, confined to Australian region.
- (d) Most important character of mammals is the presence of mammary gland and internal fertilization.
- (a) Manis (Pangolin or scaly anteater) belong to the order pholidota of the class mammalia.
- 8. (b) Eutheria includes viviparous placental mammals.
- (a) Animals belonging to the order rodentia have each jaw with one pair of long rootless chisel-like incisors growing throughout life.
- (d) Mucous makes skin moist. Moist skin is helpful in respiration.
- (b) Rabbit belongs to the order lagomorpha of the class mammalia.
- (a) Didelphis (opossum) is a tree dwelling which is found in America. It is belong to the metatheria.
- 20. (b) Monotremes is a group showing peculiar characteristics as a mixture of reptilian and mammalian features.
- **21.** (b) Kangaroo (*Macropus*) found in Australian region which is belong to the order marsupilia or metatheria.
- (d) Most unique character of mammalian brain is presence of corpus callosum. It connect the two cerebral hemispheres internally.
- **34.** (b) The zoological name of common north indian hare is Lepus ruficaudatus.
- 36. (c) Double vagina is main character of marsupilia.
- (c) Except a few, only mammals possess seven cervical (neck) vertebrae.
- 42. (c) Ungulata comprises large sized hoofed mammals such as pig, horse, ass, camel, deer, sheep, goat, cow, buffalo etc. These animals are domesticated by man for centuries.
- 49. (c) The adaptations in desert lizard are(i) Burrowing in soil to escape high temperature
 - (ii) Bask is sun when temperature is low
- 50. (d) Head louse living on the human scalp as well as laying eggs on human hair is a parasite in true sense. Female mosquito is not considered as a parasite, though it needs human blood for reproduction. Koel that lays in crow's nest is just a brood parasite.
- **51.** (b) The zoological name of tiger is *Panthera tigris* in which *Panthera* is genus and *tigris* is species.
- **53.** (c) 3-chamberd Heart is found in only members of class Amphibia and Reptilia.
- **54.** (b) Diaphragm is commonly found in only mammals (kangaroo) except crocodile.
- **58.** (d) Sea lion (*Zalophus*) is a larged-eared seal. It is belong to the order carnivora.
- **62.** (d) In male platypus a grooved erectile poison spine is present on the tarsus which is served by a poison gland in the thigh. The poison is used to immobilize a female during coition.
- 64. (d) In whale, Retea mirabilia are present which store extra oxygen and help the animal to remain under water for some time.

- (d) Brain of prototherian relatively small, simple and without corpus callosum.
- 73. (a) In prototherian, mammary glands are modified sudorific glands and they lack the nipples or teats.
- **75.** (c) Marsupium or marsupial pouch is the main characteristic of metatherian (mammals).
- (d) Echidna (Tachyglossus) is found in Australia, New Guinea and Tasmania.
- 77. (b) Members of order Monotremata of sub class prototheria are oviparous. i.e. egg laying mammals. e.g. Echidna (Tachyglossus), Ornitho-rhynchus (Duck billed platypus).
- (c) Order Primata includes lemurs, loris, tarsiers, monkeys, apes and man.
- (a) Order Insectivora comes under sub class Theria of class Mammalia.

Critical Thinking Questions

- 2. (b) Trichinella spiralis shows viviparity.
- (a) Nutritive muscular cells bear both flagella and pseudopodia.
- (b) Trichocysts of Paramecium and nematocysts of Hydra are the organ cells of offence and defence.
- (b) In Hydra, undigested residues are egested from coelenteron through mouth and body wall.
- **10.** (a) *Taenia saginata* is also 'unarmed tapeworm' because the scolex does not possess hooks.
- **14.** (d) Dorsal blood vessel is collecting blood vessel in the segments 14 onwards and distributing blood vessel in segments 1 to 13.
- **15.** (a) Blood glands of *Pheretima* serve for the manufacture of blood corpuscles and haemoglobin.
- 17. (c) Weberian ossicles refer to a paired chain of three or four small bones in certain fishes e.g. Carps and cat fishes. It connects the air bladder with auditory capsule.
- 19. (b) Presence of notochord, Dorsal tubular nerve cord, Pharyngeal gill clefts, post anal tail, RBCs and hepatic portal system is distinguising feature of chordates.
- 21. (a) Crocodile is an exceptional case of reptile having 4 chamber in heart while other reptile shows 3 or 3½ chambered heart.
- (d) All these (coelacanth, limulus and sphenodon) are representative of its own kind hence called living fossil.
- 24. (d) The characteristic feature of amniota is the development of amnion and other foetal membranes during development. Amnion and other foetal membranes are developed in reptiles, birds and mammals.
- 25. (b) Tunicates (Herdmania) shows retrogressive metamorphosis which results in the degeneration in adult.
- 28. (a) In mostly cartilagenous fishes caudal fins (Tail fins) forms two unequal lobe, which act as steering organ in locomotion.
- 29. (c) Stenohaline fishes have only a narrow range of salinity tolerance and hence remain restricted to either fresh or salt water.

- 30. (b) Two type of air bladders are known. In the more generalized groups of teleosts, the air bladder retains connection with the gut via a pneumatic duct, just as in ganoids and dipnoi. Such an open air bladder is called physostomous. In the teleost Erythrinus the air bladder has a lateral attachment to gut. Such a closed or ductless air bladder is called physoclistous.
- **31.** (b) Catla, Labeo and cirrhinus are fresh water fishes. These are important cultiable species in india.
- (a) Enterocoelic coelom is found in echinoderm to chordates.
- **34.** (b) Python captures its prey and directly engulfs it by creating suction pressure inside its mouth.
- **35.** (b) Ophisaurus is a limbless lizard also known as glass snake.
- 36. (a) Pisces and amphibia are anamniotic while reptiles, aves and mammals are amniotic.
- (a) Anapsida has a solid roof due to the absence of any temporal vacuties on skull.
- **39.** (b) All flightless birds belong to the super order Ratitae e.g. Emu, Panguin, Rhea, Kiwi, Moa, Cassowary.
- **40.** (d) The presence of seven cervical vertebrae is common feature of mammals.
- 45. (d) Sea cows (Rhytina) belong to order Sirenia of mammals. Presence of blubber and few hairs are characters of order sirenia.
- 46. (c) Silver fish belong to insecta in which respiratory organ is trachae, scorpion belong to Arachnid which respiratory organ is book lung sea squirt (Herdmania) belong to urochordata, which respiratory organ is pharyngeal gills.
- (c) Sponges "multicellular grade" organism but exhibit cellular level of organization.
- 48. (c) Embryonated eggs → Mouth → Intestine → Liver → (2nd stage larva)
 Heart → Lungs → trachea → Pharynx → Intestine.

(4th Stage larva)

- 49. (d) Cockroach and earthworm have common type of spermatheca. The spermathecae receive and store sperm cells during copulation.
- 50. (a) Earthworm is a bisexual or hermaphrodite but always shows cross-fertilization due to protandrous conditions.
- 54. (a) Reptiles, aves and mammals are amniotes while amphibia is an anamniote.
- 55. (a) Bioluminescence is a method of light producing by living organisms in which usally certain protein called luciferins in the presence of oxygen and an enzyme luciferase, are converted to oxyluciferins with the libration of light.
- (b) In some gymnophiona, dermal scales are embedded in dermis. Skin shows transverse wrinkles.
- (a) Pseudocoelom formed by blastocoel surrounds the alimentary canal in Nematodes (Ascaris).
- **59.** (c) Salamandra is a tailed amphibian, has tymphanum which represents ear.

- 60. (b) Circadian rhythm or diurnal rhythm is any 24 hour periodicity in the behaviour or physiology of animals or plants. Examples are the sleep/activity cycle in many animals and the growth movements of plants. Circadian rhythms are generally controlled by biological clocks
- **64.** (a) Although the *Amoeba* has no sense organs, it responds to chemical stimuli. It makes this determination by chemotaxis, a kind of chemical sense. This is the same response mechanism that our white blood use when they encounter and phagocytize a pathogen.
- **73.** (b) Members of *ctenophora*, *cephalochordate* and echinodermata are exclusively marine.
- 74. (b) A Insects
 - B Molluscs
 - C Crustaceans
 - D Other animal groups.
- (b) Exoskeleton is mainly responsible for diversification of insects on land.

Assertion and Reason

- (e) Sponges are the lowest multicellular animal but they
 have simple structures. Organs and tissues are absent.
 The constitution cells perform their functions more or
 less independently exhibiting division of labour
 performing specialized functions. Hence, they possess
 cellular level of organization.
- (d) In Mollusca, circulatory system is of open type with a heart made up of two auricles and a ventricle. The blood has haemocyanin.
- 3. (a) Leucosolenia shows simplest (ascon) type of canal system. In this, surrounding water enter the canal system through ostia. This water of sea enters into the spongocoel and pushed out readily through osculum. Course taken by the water current in the body of sponge may be shown as under.

 $\begin{array}{ccc} & & & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & \\ & & \\$

- 4. (e) Robert Grant (1857) was the first to recognise and prove the true animal nature of sponges. The animal nature of sponges was well established on the following grounds-
 - (i) Sponges feed on inwafted solid particles. Their mode of nutrition is truely holozoic.
 - (ii) Sponge cells are devoid of cellulose cell walls.
 - (iii) Life cycle of sponges include swimming ciliated larval stages resembling those of other marine animals. Sponges are sessile and digestion is very simple without any apparent way of capturing food or eliminating wastes.
- 5. (a) The duck billed platypus and the spiny anteater are primitive oviparous, reptiles like mammals and these are included in subclass prototheria of class mammalia. Both of them have 12 pairs of cranial nerves and 7 pairs of cervical nerves.

- 6. (b) Tape worm belonging to phylum platyhelminthes, pinworms and roundworm belonging to phylum nematoda, are all endoparasites. They all are intestinal parasites. In case of Taenia solium man gets infection by uncooked or improperly cooked measly pork. Cysticercus becomes active on reaching the intestine. Proscolex everts or evaginates in the intestinal wall. Ascaris, being an endoparasite inhabits the small intestine of man, more frequently of children than of adults. Man gets infection by consuming contaminated or uncooked food and water. Enterobius vermicularis or pinworm live in caecum, appendix and at the junction of large and small intestine. They are also transmitted in the same way like Taenia and Ascaris.
- 7. (c) Coelenterata is the phylum of acoelomate and radially symmetrical lower invertebrates. Due to their radial body symmetry they are also known as radiata. Bilateral symmetry starts from the phylum platyhelminthes.
- 8. (c) H. viridis is green in colour. Its bright green colour is not because of chlorophyll containing chloroplasts, but due to the presence of symbiotic zoochlorallae, Chlorella vulgaris, a unicellular green alga, that lives in its gastrodermal cells.
- 9. (a) Coelenterates possess a very primitive type of nervous system. This system is composed of many nerve cells. In coelenterates, the separate mechanisms for digestion, respiration and excretion, reproduction etc evolved for the first time. Thus there is a constant need to maintain coordination between these systems. Nerve cells are developed for this purpose, for the first time in coelenterates. Nerve in Hydra is the beginning in the evolution for nervous system.
- 10. (b) Realm is a large landscape (generally subcontinental) having its unique biodiversity. South Asia (including India) occurs in oriental realm; king cobra is endemic here and kangaroo is found in Australian realm. Wallace line is the imaginary line separating oriental and Australian realms.
- 11. (b) Bats and whales are the members of class Mammalia (L. Mamma = breast). The bats are the only mammals which have wings can realy fly while whales are the largest animals in existence. Both bats and whales have four chambered heart but birds and crocodiles also have four chambered heart.
- 12. (b) The birds are the most beautiful among the animals. They show court ship, nest building, parental care, migration and territorial behaviour. Koel (Eudynamis) does not make any nest but lays eggs in the crow nest. In this way koel is nest parasite.
- 13. (a) Hydroid colony of Obelia is dimorphic, exhibiting two types of individuals or zooids which differ both morphologically as well as physiologically. These two zooids are-
 - (i) Polyps the nutritive zooid of the colony
 - (ii) Gonangium the reproductive zooid.

UNIVERSAL BOOK DEPOT 1960

300 Animal Kingdom

- 14. (a) Alternation of generations may be defined as a phenomenon whereby, in the life history of an organism, a diploid asexual phase and a haploid sexual phase regularly alternates with each other. This type of true alternation of generations is also called metagenesis. In coelenterates, an asexual polypoid generation appears to alternate regularly with a sexual medusoid generation.
- 15. (a) Lateral line system of fishes and aquatic larval amphibians whose receptors are group of sensory cells derived from ectoderm.
- 16. (c) F. hepatica undergoes both aerobic and anaerobic respiration depending on the availability of oxygen. Oxygen content in bile being extremely low, respiration in F. hepatica is anaerobic or anoxybiotic. This is an exothermic reaction involving release of energy (heat). If free oxygen is available, aerobic respiration takes place.
- (c) Plasmodium vivax is responsible for malaria. It spreads by bite of female Anopheles. Its spread does not have any relation with polluted water.
- 18. (a) Birds have many adaptations for flight. They have pneumatic bones and only one ovary which reduces the body weight.
- 19. (d) Shark is a cartilagenous fish and lack buoyancy regulating organ called Swim bladder. These fishes swim constantly or will sink to the bottom. They cannot stay at a desired level in water without swimming.
- **20.** (b) Sponges belong to Porifera and they have characteristic canal system.
- (c) Malaria can not be transmitted by the bite of male Anopheles mosquito it does not carry active stage of Plasmodium.
- 22. (b) In cold blooded animals, there is no fat layer below skin and their temperature varies with the environment. These animals use their body fat during hibernation to carry out.
- 23. (b) Acraniata includes marine forms without head or cranium. They lack jaws, vertebral column, paired appendages.
- 24. (b) Spicules help in making skeleton of sponges. These are made up of silica, calcium or spongin substances. The structure of spicules also help in classification of sponges.
- 25. (c) Cephalization is the differentiation of head at anterior end. This does not play any role in appearance of animal but it may involve in accumulation of nervous tissue and sense organs in head.
- 26. (b) Insects blood is colourless. The blood also does not play any role in transport of oxygen. Insects have tracheal respiration.
- 27. (b) In lophodont condition, found in elephants, there is an intricate folding of enamel and dentine. Cresentic enamel cusps are connected by several transverse ridges called lophos. A single large lophodont molar, 30 cm by 10 cm, is present at one time in each half of each jaw. These are adapted to grind all sorts of plants, including grasses.

- 28. (b) One of the important human filaria is the African eyeworm Loa loa, transmitted by mangofly chiefly found in Africa. They commonly invade subcutaneous tissue and during their migration may pass across the eye-ball, hence the name eyeworm.
 Loa microfilariae is very injurious and fatal when they penetrate brain and spinal cord and perhaps carry neurotropic viruses. During their migration, they cause itense itching and swelling. They also cause swelling
- 29. (b) The body of annelids is divided into segments called metameres, externally ring like grooves (annuli) and internally by vertical partitions called septa. The external segmentation corresponds to internal segmentation. This phenomenon is called metamere or metameric segmentation. Phylum annelida represents the first group of metazoan animals developing a true coelom with metameric segmentation.

and pain in eyes, known as "calabar swellings".

- 30. (b) In annelida, blood is red due to the presence of haemoglobin or erythrocruorin dissoved in plasma. RBCs are absent in them. Blood corpuscles are colourless. Instead of blood, leeches posses reddish haemocoelomic fluid that flows in haemocoelomic channels.
- 31. (c) In whale bone whales, teeth are absent. Instead, the upper jaw carries two transverse rows of numerous triangular fringed horny plates of baleen or whale bone. This serves as the effective sieve for straining plankton (mostly krill) which forms their chief food.
- 32. (a) In annelida four pairs of flask shaped sacs, each with a diverticulum for storage of sperms and large ampulla for their nourishment is present. Spermathecae occur in 6-9 segments. They receive sperm during copulation. As cross fertilization occurs in earthworm, the sperms of one worm are transferred to spermathecae of the other.
- Rabbits). This is the process by which many rodents form a special kind of faeces from the contents of the caecum and these are reingested, so that the food passes through the digestive system second time. Rabbit is coprophagus in habit, eating its own faeces in order to get maximum amount of nutrient from its food. Faeces produced during night alone are eaten up which are soft and moist due to incompletely digested cellulose. Thus passing through the gut once more, the faeces are subjected once again to digestion and absorption.
- 34. (b) All the sternal parts of the thoracic ribs except the last five, attached the sternum below by hyaline cartilage. Therefore, they are called as true ribs. Actually last two pairs of ribs (11th and 12th pair) provided with the sternal parts and they are not connected with the sternum and hence, known as floating ribs. Floating ribs protect the kidney.

- 35. (b) Sweat glands produced from stratum germinativum, plays an important role in the regulation of body temperature. When the body temperature rises too much, the sweat glands are stimulated to take up water from blood vessels and to pour out their secretion on the general surface of the skin. Evaporation of sweat from the body surface uses up latent heat of vaporization from the skin, thus the extra heat of the body is used up and the body cools down reducing the temperature.
- **36.** (c) Aquatic annelids excrete ammonia, and terrestrial species (earthworm) excrete urea. However, earthworms are less ureotelic than other terrestrial animals. Excretory fluid contains 40% urea, 20% ammonia and 40% amino acids and other nitrogenous compounds, but no uric acid or urate.
- 37. (a) Most arthropods certain molluscs and tunicates contain open circulatory system. In them, a fluid composed of blood mixed with tissue fluid bathes with internal tissues and organs directly. It oozes through spaces or cavities that surround the organs, this mixture of fluid is usually referred to as haemolymph.
- 38. (a) Birds have a constant body temperature which commonly remains in between 104° to 112°F, even in subzero weather. Thus they are called homoiothermal. The feathers serve the most important function of retention of heat. Because the plumage forms an efficient, non-conduction covering with its innumerable dead air spaces, useful as insulation. In cold weather, the heat loss is reduced to minimum by fluffing out the feathers, which increases the depth of insulating material by adding to the air spaces within the feathery layers. In warm weather, the feathers are often held close to the body to allow some escape of body heat.
- 39. (e) Moulting or ecdysis occurs not only in invertebrates, but in birds also. In birds, shedding and replacement of feathers is moulting or ecdysis which takes place gradually, moulting usually takes an average time of six weeks. At the base of each feather follicle, a dermal papilla persists from which new feathers will form. Thus there is a continuous replacement of feather throughout life. The replacement of feathers is seasonal in some birds such as peacock, while in other birds such as pigeon it is gradual throughout the year.
- 40. (b) Though pigeons have no mammary glands, (as they belong to class aves not to mammals), milk is secreted by them. The pigeons are oviparous, the eggs are laid in the nest and are incubated by the warmth of the parent's body and hatching occurs after a fortnight. The immature, helpless and featherless young ones are nourished by parents by a fatty curdy secretion, the pigeons milk which is secreted in their crop. The parental care and homing instinct are well developed in pigeons.
- 41. (b) The poison apparatus of snake consists of a pair of poison glands, their ducts and a pair of fangs. The poison glands are situated one on either side of the upper jaw. The poison glands are possibly the superior labial glands or parotid glands. The fangs are sharply pointed and are enlarged maxillary teeth.

- 42. (c) The hemipenes are the copulatory organs found in Uromastix and some other reptiles. These are two eversible hollow sacs lying under the skin behind the cloacal aperture at the base of the tail. Proximally, the hemipenes communicate with the urodaeum of the cloaca. During copulation, only one hemipenes, is inserted into the cloaca of the female. Erection of the hemipenes is due to the muscular action and filling with blood, then they are everted and become cylindrical and project beyond the cloaca.
- 43. (a) Parental care is clearly seen in amphibians. They protect their eggs by keeping them —

 (i) In enclosures in the water, (ii) In holes near water, (iii) In nests, on trees or on rocks, overhanging water, (iv) In transparent gelatinous bag in the water, (v) On trees or in moss, away from water. They also show direct nursing by the parent. The examples are—

 (i) Tadpoles transported from one place to another by
 - (i) Tadpoles transported from one place to another by males, (ii) Eggs protected by male who covers with his body, (iii) Eggs carried round the legs by the female, on the back of the female etc.
- 44. (a) The entire skin of frog serves as organs of touch as it is abundantly supplied with sensory nerve endings situated in the spaces between the cells. Thus the skin is called tangoreceptor. At places, groups of epidermal cells-tactile organs and patches are present. These are very much sensitive to touch and also to temperature. The tactile organs make the skin of frog sensitive to touch, heat, cold and the effects of the chemicals.
- 45. (a) From the diffused lymphatic system lymph is pumped back into veins by two pairs of lymph hearts. One of which is situated just behind the transverse processes of the third vertebra opening into the sub scapular veins, the second pair of lymph hearts is found on either side at the end of the urostyle. They open into the femoral vein.
- 46. (b) In frog, most of the absorption takes place in intestine. The intestine of frog is so formed, that it gives the greater surface area. The intestine is the longest part of the alimentary canal where the absorption of the digested food materials take place.

 To increase the absorptive surface of the intestine, the internal lining of the intestine forms transverse folds in the duodenum and longitudinal folds in the region of the ileum and rectum.
- 47. (a) Amphibia is cold blooded or ectothermal animal as its body temperature does not remain constant but fluctuates with that of environment. Thus it is called poikilothermal animal. In winter the temperature of the body activities ceases down. In this condition it can not live more on the land, so it takes winter sleep or hibernation in underground. Similarly during the summer it once again goes underground to sleep as its all body activities are slowed down due to high temperature. This is known as summer sleep.
- 48. (c) In fishes, the heart is mainly two chambered one auricle and one ventricle. Heart of Scoliodon receives only deoxygenated or venous blood, hence named as venous heart. The auricle opens to the ventricle through atrioventricular aperture. Mainly the impure blood passes from the heart to the gills only once. Therefore, they have single circulation only.

- 49. (b) The ampullae of Lorenzini are found in clusters on the dorsal and ventral surfaces of the head embeded below the skin but opening externally on the surface of the skin. The ampullae of Lorenzini were formerly regarded as neuromast organs but Sand (1938) has proved that these are thermoreceptor organs. The change in the temperature of water is carried to the brain through the ampullary receptors.
- 60. (a) A faint line runs on either side of the body extending from the head to the posterior end of the tail, this is called lateral line (also called neuromast system). It marks the position of an underlying canal which runs along side of the body and contains special receptor organs. The lateral line canal extends anteriorly into the head, where it branches into several canals; at intervals these canals opens to the exterior through the pores. These canals contain neuromast organs like rheoreceptors or current receptors. The latter can perceive vibration of very low frequency and detect disturbances in water.
- 51. (b) Following are the characters of cyclostomes showing an advance over Amphioxus. A distinct head, however may be secondary, a so-called cranium, a more advanced brain, pro and mesonephric kidneys, secondary notochord, vertebrae introduced (lampreys) etc. Cyclostomes also have some particular specialization like tongue apparatus, sucking mouth with horny teeth, sac-like gill pouches, separate branchial sac with branchial basket etc.

The degenerated characters of cyclostomes are -

(i) tongue apparatus (ii) rudimentary paired eyes in hagfishes (iii) lack of exoskeleton (iv) reduced liver and lack of gall bladder and bile duct in adult lamprey.

- 52. (a) Amphioxus is devoid of heart, head, kidneys and paired limbs. Paired sense organs are absent here receptors are of primitive types. A complete notochord is persistant with no vertebral column. This shows that it has a simple organization compared to vertebrates because many important craniate structures are lacking in it. But it is definitely a simple chordate having a large number of primitive characters such as a notochord, dorsal hollow nerve cord, and gill clefts.
- 53. (a) The life cycle of fresh water mussel, including a parasitic glochidium larva on a fish host has many advantages. Besides affording protection and a means of nourishment, it ensures a far wide and more rapid dispersal of the species. A fish may carry these tiny parasites to great distances before they drop off. Considering the sluggish habits and poor locomotory ability of the mussels, this is probably the only way to ensure their proper distribution.
- 54. (a) In Amphioxus, some exchange of O2 and CO2 occurs between the water current and blood through the gill-clefts, but this appears doubtful since the blood contains no respiratory pigment. The pharyngeal wall of Branchiostoma is richly vascular and the water current entering the pharyngeal cavity brings O2. The blood flows so close to the surface that some exchange between CO2 of blood and O2 of water can easily occur. It appears more probable that an exchange of gases occurs over the whole surface of the body and particularly in the walls of atrium.

- development of gastropods, which rotates the visceropallium anticlockwise brought 180° from its initial
 position, so that mantle cavity, with its pallial complex,
 is through in front of the body in adult. Changes
 occuring in torsion are to certain extent reversible. This
 reversion is known as detorsion and it is a very
 characteristic of the whole group of the euthyneura.
 Formerly, this condition was looked upon as an
 arrested stage in the torsion, but there is the same
 reduction of the paired parts of the pallial complex as in
 the specialized streptoneura. Total detorsion, as shown
 by the typical opisthobranchia is accompained by the
 reduction of disappearance of the shell.
- 56. (c) Each ambulacral groove of echinoderms contains two double rows of short, tubular retractile projections, called as podia or tube feet, that end in suckers. Tube feet are characteristic organs of echinoderms serving variously for locomotion, capturing of food, respiration etc.
- 57. (c) In the mid ventral wall of pharynx is a shallow groove called endostyle. The endostyle is lined with gland cells which secrets mucus. The larval endostyle is lost during metamorphosis of lamprey, it contributes to the formation of a thyroid gland in the adult. Like thyroid it concentrates radioactive iodine in itself. Similar endostyle is found in urochordate and the ammocoete larva of lampreys.
- 58. (a) Digestive mechanism of Herdmania is similar to that of higher group of animals due to possessing several enzymes used in digestion. In Herdmania, the liver secretes a yellowish-brown digestive fluid into the stomach, it has many enzymes, an amylase which splits carbohydrates into maltose, a protease which breaks down proteins and a weak lipase which probably acts on fats. And also secretion of pyloric gland probably has an accessory digestive function similar to that of pancreas.
- 69. (d) Pygochord is longitudinal rod like structure extending from the ventral side of the intestine to the body wall, in the post hepatic region of the trunk. Its cells are vacuolated. It supports the post hepatic region of the body but probably also performs some other functions not yet understood.
- 60. (b) Water vascular system or ambulacral system is a unique system of echinoderms which helps mainly in locomotion. It is infact a modified part of coelom consisting of a system of canals containing sea water and amoeboid corpuscles. It helps in locomotion by providing a hydraulic pressure mechanism of tube feet may serve for respiratory exchange of gases. Tube feet also help in anchoring the body to substratum and in capturing and handling the food.
- 61. (c) Balanoglossus belong to class enteropneusta. In certain cases, the proboscis pore does not communicate with the proboscis coelom, but terminate blindly, and may send off a narrow tubular diverticulum which opens into the neurocoel. The proboscis sits in the collar somewhat like an acorn in its cup, a character that has given the name "acorn worm" to the group.

ET Self Evaluation Test

1.	Select incorrect pair [MP PMT 2009]	11.	Which of the following is not found in birds [CBSE PMT 1999]
	(a) Porifera-choanocytes (b) Coelenterata-nematocysts		(a) Hind limb (b) Fore limb
	(c) Annelida – segmentation (d) Monera – eukaryote		(c) Pelvic girdle (d) Pectoral girdle
2.	Which of the following is a chordate feature, not shared by	12.	
	the non-chordates	12.	
	[AIIMS 2001; CBSE PMT 2002; CPMT 2005]		(a) Beroe (b) Hydra (c) Sponges (d) Labeo
	(a) Metamerism (b) Axiate organization	13.	
	(c) Bilateral symmetry (d) Pharyngeal gill slits	13.	Paired appendages are not found in [AFMC 2008] (a) Hemichordates (b) Urochordates
3.	Which one of the following invertebrates is a deuterostome		
	and enterocoelous coelomate [MP PMT 2000]	14	(c) Cephalochordates (d) All of these
	(a) Pila (b) Ascaris	14.	Which of the following group is Deuterostome
	(c) Aphrodite (d) Asterias		[Kerala PMT 2000; RPMT 2001]
4.	Helically coiled shaped "X" organ is found in		(a) Annelida, Arthropoda, Mollusca
	[Odisha JEE 2008]		(b) Echinodermata, Hemichordata, Chordata
	(a) Crustacea (b) Porifera		(c) Annelida, Mollusca. Chordata
	(c) Insecta (d) Amphibia		(d) Arthropoda, Mollusca, Echinodermata
5.	Scoliodon is called dogfish due to one of its following	15.	Discoblastula found in [MP PMT 2011]
	characteristics [MP PMT 2000]		(a) Echinoderms and amphioxus
	(a) Mouth (b) Gait		(b) Reptiles, birds and fishes

- (d) Chordates show the presence of nerve cord, Notochord and pharyngeal gill slits.
- (d) Echinodermata and all chordates are deuterostome and enterocoelous.
- (d) In scoliodon, olfactory organs are characteristically large in elasmobranchs correlated with a highly developed sense of smell for perception of chemical substances dissolved in water.
- 7. (a) Placoid scale has a disc like basal plate. It resembles a tooth. These scales are found in cartilagenous fishes (chondricthyes).
- **8.** (b) Icthyophis is a limbless amphibian showing parental care. It has no tongue.
- 10. (d) Sharks and dogfishes have cylindrical body while skates and rays have flattened body with winglike pectoral fins which are not distinct from body.

- (b) In birds, forelimbs are modified as wings for flying.
 Therefore, the forelimb is not found in birds.
- 14. (b) Deuterostomes includes Echinodermata, Hemichordata and chordata. The mouth is derived away from the blastopore.
- 17. (d) Hypnotoxin is secreted by nematocyst cell of tentacles of hydra to paralyse the active prey for easy engulfing.
- (a) Loss of gravid proglottids from posterior end of body is called apolysis.
- 20. (a) Because they are supposed to be associated with the function of excretion just like liver.
- 22. (c) In diptera, hindwings are greatly reduced to drumstick shaped structures, called halters. These carry sense organs and serve as balancing organ during flight.
- 25. (d) An individual with both male and female reproductive organs called hermaphrodite.
- 28. (b) The second stage of juvenile is infective stage of Ascaris which is also called embryonated egg.
- 29. (d) Annelids are first animals in which closed circular system, metamerism segmentation and true coelom is evolved. On the basis of these comments annelids are advanced over nematoda.
- **30.** (b) Presence of two pair antennae is character of class crustacea. Antennae are sensory and help in searching food and shelter.
- 34. (a) The excretory system of crustacea (Palaemon) consists of a pair of antenary or green glands, a pair of lateral ducts and an unpaired renal or nephroperitoneal sac coxa of each antenna encloses an antennary gland.
- 35. (b) Pancreas is absent in cyclostomates, a class of Agnatha. The pancreas is derived from the endoderm of embryo. It lies inferior to the stomach in a bend of the duodenum. It is both an exocrine and endocrine gland.
- **38.** (a) All these three animals are Homeiothermic; although platypus is incomplete homeiothermic.
- 39. (b) In invertebrates nerve cord is found in ventral position that is a part of CNS.

Morphology (Gr. Morphos = Form; logos = Study) is the branch of science which deals with the study of form and structure. In botany, it generally means the study of external features, forms and relative positions of different organs on plants.

Parts of a flowering plant: Flowering plants consist of root, stem, leaves, flower, fruits and seeds.

The root

The root is usually an underground part of the plant which helps in anchorage of plant in soil and absorption of water and minerals from the soil. The root with its branches is known as the root system.

Characteristics of the root

- (1) The root is the descending portion of the plant axis and is positively geotropic and negatively phototropic.
 - (2) It is non-green or brown in colour.
- (3) The root does not bear nodes, internodes, leaves and true buds.
 - (4) Usually the root tip is protected by a root cap.
 - (5) The root bears unicellular root hairs.
- (6) Lateral roots arise from the root which are endogenous in origin (arise from pericycle).

Parts of the root

(1) Region of root cap: The tip of the root is called calyptra or root cap. It is for protection of root tip against any injury. It is formed from meristem called calyptrogen. Pandanus is the only plant with multiple root caps. In the aquatic plants like Pistia, Lemna and Eichhornia instead of root caps, they have root pockets for buoyancy. The root caps are absent in parasites and mycorrhizal roots.

- (2) Region of cell formation or meristematic zone: This region of cell division lies protected below the root cap. It comprises of closely arranged, small, thin walled and isodiamatric cells which have dense protoplasm. Vacuoles of the cells are either reduced in size or absent.
- (3) **Region of cell elongation**: It lies behind the growing point. Cells of this region lose power of division. The cells elongate due to vacuolation *i.e.*, formation of vacuoles.

This region chiefly concerns with absorption of minerals along with some amount of water.

(4) Region of cell differentiation or maturation (Root hair zone): In this region elongated cells are differentiated into permanent tissues depending upon the functions they have to perform. It lies adjacent to the meristematic region some cell of the outermost layer of cells in this region develop root hairs. Most of the water absorption occurs through this region.

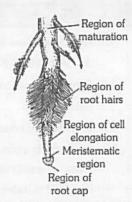

Fig: 2.1-1 Regions of the root

Types of root

Tap root: Tap root is the primary root which develops from the elongation of the radicle of embryo and persists throughout the life of plant. It forms lateral branches or secondary roots which are further branched to form tertiary roots. Thus tap root along with its branches *i.e.*, secondary and tertiary roots form tap root system.

Adventitious root: The root system that develops from any part of the plant body other than the radicle is called the adventitious root system. It is mostly seen in monocotyledonous plants. In grasses, fibrous root system is present.

Modification of roots

Sometimes the root performs functions other than fixation, absorption and conduction so get modified structurally. Both tap roots and adventitious roots may undergo such modifications. There are many types of root modifications.

Modification of tap roots

- (1) Storage roots: In some plants, the primary tap roots are modified for storing reserve food materials. The secondary roots remain thin and they are absorptive in function. The storage roots are usually swollen and assume various forms:
- (i) **Conical**: The swollen root is broad at the base and tapers gradually towards the apex giving a shape of cone, e.g., Carrot.
- (ii) **Fusiform**: The root is swollen in the middle and narrow towards both its base *e.g.*, Radish (*Raphanus sativus*).
- (iii) **Napiform**: The root is nearly globular or spherical in shape. The basal portion of root is much swollen which suddenly tapers towards the apex giving a top-shaped appearance, e.g., Turnip (*Brassica napus*, vern, Shalgam) and Beet (*Beta vulgaris*, vern. Chukandar).

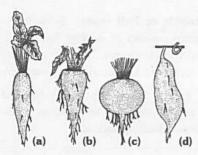

Fig: 2.1-2 Tap root modifications (a) Fusiform (b) Conical (c) Napiform (d) Tuberous

(iv) **Tuberous**: The storage root having no definite shape is called tuberous, .e.g., Mirabilis jalapa (4 O'clock plant).

(2) Branched roots

(i) **Nodular roots** (**Tuberculated roots**): The primary tap roots and its branches of leguminous plants, *i.e.*, plants belonging to sub-family papilionatae of the family leguminosae (e.g., Pea, Gram, Ground nut, Beans etc.), bear nodule like swellings, called root nodules.

They are red in colour due to the presence of leghaemoglobin. The nodules are inhabited by nitrogen fixing bacteria called *Rhizobium leguminosarum*. It converts atmospheric nitrogen into nitrates and supply them to the plant. In turn *Rhizobium* gets nutrients and shelter from the plant.

(ii) Pneumatophores or Respiratory roots: The roots of some plants growing in saline marshes (mangrove plants) suffer from the lack of oxygen. This is due to the water logged condition of the soil. To cope with this situation some root branches grow vertically upwards.

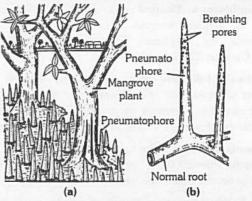

Fig: 2.1-3 Pneumatophores:
(a) Plants showing pneumatophores
(b) Part of pneumatophores showing breathing pores

They become aerial and negatively geotropic. These roots bear many minute pores called pneumathodes (lenticels) towards their upper ends. Gaseous exchange takes place through pneumathodes. Such aerial, porous, roots which help in gaseous exchange are called breathing roots. e.g., Sonneratia, Heritiera, Rhizophora, Avicennia and Ceriops etc. and are found in sundarbans of West Bengal.

For physiological or Vital functions

(1) **Storage roots**: The roots where adventitious roots become swollen to store food. They are of following types:

Tuberous roots: These adventitious roots are swollen without any definite shape e.g., *Ipomoea batata* or (Sweet potato).

Fasciculated roots: These are tuberous roots arising in cluster from the base of the stem. e.g., Dahlia, Ruellia (Menow weed), Asparagus etc.

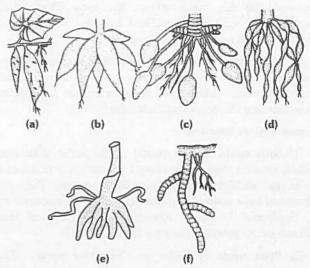

Fig: 2.1-4 Modification of adventitious root: (a) Tuberous root of sweet potato (b) Fasciculated roots of dahlia, (c) Nodulose roots of mango ginger, (d) Moniliform root of Momordica, (e) Palmate roots of Orchis, (f) Annulated roots of Ipecac

Nodulose roots: These roots become swollen at their tips due to accumulation of food *e.g.*, *Maranta* sp. (Arrowroot), *Curcuma amanda* (Mango – ginger).

Moniliform or Beaded roots: These adventitious roots are swollen at frequent intervals. This gives the root a beaded appearance. e.g., Portulaca (Rose moss), Momordica (Bitter gourd), Cyperus (Guinea rush).7

Palmate tuberous roots: In Orchis there is a pair of succulent tuberous root, one of which perishes every year while another new one is formed by its side. Such orchid roots may sometimes be of palmate shape, therefore, called palmate roots.

Annulated roots: The roots of a medicinal plant, Cephaelis ipecacuanha (Ipecac) yields emetine that looks like discs placed one above another, therefore, called annulated.

- (2) **Epiphytic roots**: These roots are also called 'hygroscopic roots'. These roots develop in some orchids which grow as epiphytes upon the trunks or branches of trees. They hang freely in the air and absorb moisture with the help of special sponge like tissue called velamen. Velamen is modification of epidermis. e.g., Vanda, Dendrobium etc.
- (3) Parasitic or Haustorial or Sucking roots: The roots of parasitic plants, which penetrate into the host tissues to absorb nourishment, are called haustorial roots. e.g., Cuscuta (Dodder, Vern, Amarbel).
- (4) Saprophytic roots (Mycorrhizal roots): The roots are associated with fungal hyphae either superficially (ectomycorrhizae) or internally (endomycorrhizae) for absorption of water and minerals. e.g., Monotropa and Sarcodes.
- (5) Photosynthetic or Assimilatory roots: These are green, aerial, adventitious roots which prepare food materials by photosynthesis are called photosynthetic roots or assimilatory roots e.g., Taeniophyllum, Trapa and Tinospora. In some epiphytes like Taeniophyllum, the stem and leaves are absent. The entire plant is represented by thin green, ribbon like roots which contain velamen. These roots absorb moisture from the atmosphere and manufacture food materials by photosynthesis.
- (6) **Reproductive roots**: Some fleshy adventitious root develop buds which can grow into new plants. These are called reproductive root. These roots serve as means of vegetative propagation. e.g., Sweet potato, *Dahlia* etc.

For mechanical function

- (1) Stilt roots (Brace roots): The aerial, adventitious obliquely growing roots that develop from the lower nodes of the stem to give additional support are called stilt roots. These roots bear several large overlapping root caps called multiple root caps. e.g., Sugarcane, Pandanus, Rhizophora, Sorghum and Maize. Pandanus (screw pine) is a common sea shore plant.
- (2) Prop roots or Pillar or Columnar roots: These adventitious aerial roots arise from horizontal aerial branches of the trees like Ficus benghalensis (Banyan). They grow vertically downward, penetrate the soil, become thick and assume the shapes of pillars. They provide support to the spreading branches of tree. Prop roots possess lenticels for aeration.

In India, the biggest banyan tree having large number of proproots are found at Indian Botanical Gardens, Kolkata and Kadiri (Andhra Pradesh).

- (3) **Buttress roots**: The horizontal plank like aerial, adventitious roots that develop at the base of the stem to give additional support are called buttress roots or ballast roots, *e.g.*, *Terminalia* and *Salmalia*.
- (4) **Climbing roots**: The aerial adventitious roots that arise from the nodes or internodes of weak stemmed plants to climb up

their support are called climbing roots, e.g., Pothos, Piper betel, Vanilla and Hedera. In Pothos and Hedera, climbing roots develop all over the stem. In Vanilla, single tendril like root arise at each node. Hence they are called tendrillar roots. In Piper betel, many short branched, adventitious roots arise at each node. These roots are called clinging roots.

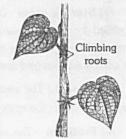

Fig: 2.1-5 Climbing root of Piper betel

- (5) Floating roots: These roots develop from the nodes of floating aquatic plants like Jussiaea (=Ludwigia). They store air, become inflated and spongy, project above the level of water, make the plant light and function as floats.
- (6) Contractile or Pull roots: Some roots of plants with underground stems contract or swell so that the aerial shoots are kept in a proper depth in the soil. These roots are called contractile or pull roots, e.g., Canna, Crocus, Allium, Lilium, Freesia, etc.
- (7) Root thorns: In aroids like Pothos and many palms (Acanthorhiza and Iriartea) the adventitious roots become hard and pointed hence called root thorns.

The stem

The stem develops from the plumule of the germinating seed. Normally it is the aerial part of the plant body.

Characteristics of stem

- (1) Stem is an ascending axis of the plant and develops from the plumule and epicotyl of the embryo.
- (2) It is generally erect and grows away from the soil towards light. Therefore, it is negatively geotropic and positively phototropic.
- (3) The growing apex of stem bears a terminal bud for growth in length.
- (4) In flowering plants, stem is differentiated into nodes and internodes. A node occurs where leaves are attached to the stem. Internode is the portion of stem between the two nodes.
- (5) The lateral organs of stem (i.e., leaves and branches) are exogenous in origin (from cortical region).
 - (6) The young stem is green and photosynthetic.
 - (7) Hair, if present, are generally multicellular.
- (8) In mature plants, stem and its branches bear flowers and fruits.

Diverse forms of stem

- (1) Reduced stems: In some plants, the stem is in the form of a reduced small disc which is not differentiated into nodes and internodes. e.g., (a) A reduced green-coloured disc-like stem lies just above the base of fleshy roots of Radish, Carrot and Turnip; (b) Green-coloured small discoid stem occurs in free-floating Lemna, Spirodela and Wolffia; (c) Highly reduced non-green discoid stem occurs at the base of Onion and Garlic bulbs, etc.
- (2) Erect stems: Majority of angiosperms possess upright, growing-ascending, vertically-erect stems. They are fixed in the soil with the help of roots.
- (3) Weak stems: They are thin, soft and delicate which are unable to remain upright without any external support. They are of two types: upright weak stems and prostrate weak stems.

(i) Upright weak stem

Twiners: The stems are long, slender, flexible and very sensitive. They twin or coil around an upright support on coming in its contact due to a special type of growth movement called nutation. They may coil the support to the right (anticlockwise from the top or sinistrorse) e.g., Convolvulus sp., Ipomoea quamoclit Clitoria ternatea, etc. or to the left (clockwise or dextrorse), e.g., Lablab.

Climbers: The stem is weak and unable to coil around a support. They usually climb up the support with the help of some clasping or clinging structure. They are of four types:

- (a) Tendril climbers: Tendrils are thread like green structure which help in climbing the plants. They may be modified stem (e.g., Vitis), stem branches (e.g., Passiflora) and inflorescence (e.g., Antigonon).
- (b) Root climbers: Adventitious roots arise from the nodes and penetrate into the upright support so that the climber climbs up, e.g., Betel vine (Piper betel), Tecoma, Ivy, etc.
- (c) Scramblers or Hook climbers: These weak stemmed plants slowly grow over other bushes and rest there. They attain this position with the help of curved prickles (e.g., Rose), curved hooks on flowering peduncle (e.g., Artabotrys), prickles on stem (e.g., Lantana), spines (e.g., Climbing Asparagus) or spinous stipules (e.g., Zizyphus).
- (d) Lianas: These are woody perennial climbers found in deep forests. At first, they are just like ordinary twiners but once they reach to the top and get sunlight, become woody, e.g., Tinospora, Ficus, Bauhinia, Bignonia, etc.

(ii) Prostrate weak stem

Trailers: The stem creep on the ground but roots do not arise at the nodes. They are of three types:

(a) Procumbent: The stem creeps on the ground totally e.g., Tribulus, Basella, Evolvulus.

- (b) Decumbent: Branches, after growing horizontally for some length, grow vertically upwards, e.g., Portulaca, Tridax, Lindenbergia, etc.
- (c) Diffuse: Branches grow profusely in all directions, e.g., Boerhaavia.

Creepers: These weak-stemmed plants grow prostrate and develop adventitious roots from their nodes. Creepers are of three kinds:

- (a) Runners: This prostrate aerial stem has a long internode and creeps horizontally. Axillary buds arise from nodes to form aerial shoots and roots. e.g., Cynodon (doob grass) and Oxalis.
- (b) Stolons: They are special kinds of runners which initially grow upwards like ordinary branches and then arch down to develop new daughter plants on coming in contact with the soil. e.g., Strawberry (Fragaria vesica), Colocasia, Peppermint (Mentha piperita), Jasminum (Jasmine).
- (c) Offsets: They are weak, elongated, horizontal branch of one internode that arises in the axil of a leaf. At the tip, it produces cluster of leaves above and tuft of roots below. The offset may break off from the parent plant and act as individual plants. They are found usually in aquatic plants and rarely is terrestrial plants. They are helpful for vegetative propagation. e.g., Eichhornia (water hyacinth), Agave, Pistia.

Modification of stem

Underground stem

The underground stems lack green colour because of their geophillous nature. They can be identified as stems because of the presence of nodes, internodes, scale leaves, buds and branches. Based on the type of growth (transverse/vertical/oblique) and the part that stores food (main stem/ branch/ leaf base), the underground stems are classified into several types :

(1) Sucker: This is a sub aerial branch that arises from the main stem. Initially it grows horizontally below the soil surface and later grows obliquely upward. They are shorter and stouter than the runners. e.g., Mentha arvensis (mint vern. Podina) and Chrysanthemum.

(2) Stem tuber: Stem tuber is the tuberous tip of an underground branch. It occurs beneath the soil at any depth. The axillary branches (stolons) that are produced near the soil surface grow into the soil and their tip become swollen due to accumulation of starch and proteins e.g., Solanum tuberosum (potato). In potato, the stem nature is evident by the presence of 'eyes' on its brownish corky surface. Each eye is a pit like structure and represents the node. Axillary bud is situated in the pit of the eye. The stem tubers are differentiated from the tuberous roots by the presence of vegetatively propagating eyes.

- (3) **Rhizome**: The rhizome is a thickened, underground dorsiventral stem that grows horizontally at particular depth within the soil. The rhizome is brown in colour. It can be distinguished from the modified root by the presence of nodes, internodes, terminal bud, axillary bud and scale leaves. The terminal bud develops aerial shoot that bears inflorescence. Adventitious roots develop on the ventral surface of the rhizome. The rhizomes are perennial and vegetatively propagating structures. It is of following types:
- (i) Rootstock: They are upright or oblique or vertical with their tips reaching the soil surface. e.g., Alocasia indica and Banana.
- (ii) **Straggling**: They are horizontal in position and generally branched (Sympodial or Monopodial), e.g., Nelumbo nucifera (Lotus), Zingiber officinale (Ginger), Curcuma domestica (Turmeric), Saccharum etc.
- (4) Corm: The corm is an underground modification of main stem with more diameter than length. It grows vertically at particularly depth in the soil. The corm stores food materials and becomes tuberous. It is non green in colour and conical, cylindrical or flattened in shape. The corm bears scale leaves at each node. In the axils of these scale leaves axillary buds arise which grow into daughter corms. The terminal bud of the corm is large.

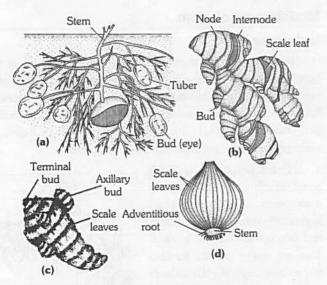

Fig: 2.1-7 Underground modification of stem
(a) Tuber s of potato (b) Rhizome of ginger
(c) Corm of colocasia (d) Bulb of onion

It grows into aerial shoot and bears leaves and flowers. Adventitious roots normally develop from the base or all over the body of the corm. With the help of some special adventitious roots called the contractile roots or pull roots, the corm remains constantly at a particular depth. The corm propagates vegetatively by daughter corms. e.g., Amorphophallus, Gladiolus, Colocasia and Crocus (Saffron).

(5) Bulb: A bulb is a specialized underground stem which bears roots on it's lower side and rosette of fleshy leaf bases or fleshy scales on the upper side. In a bulb, the stem is reduced and

- becomes discoid. On the lower side of the disc adventitious roots develop in clusters. The upper side of the disc shows compactly arranged scale leaves so as to form an underground bulb. The leaf bases or scales become fleshy due to accumulation of food (carbohydrates) and water. The terminal bud grows into inflorescence or aerial shoot (scape), while some of the axillary buds develop into daughter bulbs. Bulbs are of two types, tunicated bulb and scaly bulb.
- (i) **Tunicated bulb**: In tunicated bulb, the fleshy leaf bases are arranged in a concentric manner. The entire bulb is covered by peripheral dry membranous leaf bases called tunics, hence called the tunicated bulb. e.g., Allium cepa (Onion), Narcissus and Tulip. Compound tunicated bulbs as in Allium sativum (garlic).
- (ii) Scaly or Imbricated bulb: In scaly bulb, the fleshy scale leaves are arranged loosely overlapping one another. Such bulbs are not covered by any tunics, hence called naked bulbs or scaly bulbs. e.g., Lilium bulbifera (Lily).

Aerial stem

- (1) Tendrils: The tendrils are thin, wiry, leafless and spirally coiled branches. The terminal part of a tendril is sensitive. It holds the support by coiling round it. The tendrils help the weak stems to climb the support. In some weak stemmed plants, the axillary bud or terminal bud may modify to form tendrils which are specially called stem tendrils. Stem tendrils are of following four types:
 - (i) Axillary: e.g., Passiflora.
- (ii) Extra-axillary: e.g., Luffa (vern. Ghiatori), Cucurbita (vern. Kaddoo), Lagenaria (vern. Lauki).
 - (iii) Apical bud tendrils: e.g., Grape Vine (Vitis vinifera).
 - (iv) Floral bud or Inflorescence tendrils: e.g., Antigonon.
- (2) **Stem thorns**: The axillary buds of some plants become arrested and get modified into stiff, sharp and pointed structures, called thorns. They are deep seated structures having vascular connections with stem. Besides reducing transpiration, they protect the plant from browsing animals. e.g., Citrus, Duranta, Bougainvillea, Pomegranate, Flacourtia, Aegle marmelos etc. In Alhagi the thorns bear flowers.
- (3) **Phylloclades:** The phylloclade is special modified photosynthetic stem present mostly in xerophytes. It is green, flattened or cylindrical structure which has distinct nodes and internodes. Xerophytes show many adaptations to check the rate of transpiration. Reduction of leaf size, early leaf fall, formation of scale leaves, spines, thorns, thick cuticle, presence of fewer stomata are some of the xerophytic characters. In such cases, the stems become flattened to carryout photosynthesis. These modified stems are called phylloclades. Usually the phylloclades retain water in the form of mucilage. e.g., Opuntia, Casuarina, Cocoloba and Ruscus.

In Opuntia, the leaves are modified into spines and the stems becomes fleshy leaf like phylloclade. In Casuarina the leaves are modified into scales. The phylloclade in Ruscus is leaf like and bear flowers. In Cocoloba, after the modification of leaves into scales the stem becomes ribbon like phylloclade with distinct nodes and internodes.

- (4) Cladodes: These are modifications of stem and branches of limited growth. It has one internode only. Each cladode is green, flat or cylindrical, leaf like structure which performs photosynthesis. In Asparagus, the leaves are reduced to curved spines. In Ruscus aculeatus, the leaf like cladode are borne in the axils of scale leaves.
- (5) **Thalamus**: Thalamus of a flower is a modified stem apex. The other floral parts (sepals, petals, stamens and carpels) are born on the thalamus. It may be convex (*Ranunculus*), concave (*Lathyrus*) or flask shaped (Rosa).

Stem branching

In angiosperms, always the branches are produced by the growth of axillary buds or lateral buds. This type of branching is known as lateral branching. The lateral branching is classified into two kinds racemose and cymose.

(1) Racemose branching: In this type of branching, the terminal (or apical) bud of the main stem grows indefinitely and the axillary buds grow out into lateral branches in acropetal succession.

This type of branching is also called monopodial branching. Due to monopodial branching the shoot system of plant appears conical e.g., Eucalyptus, Polyalthia (Ashoka tree).

- (2) **Cymose branching:** In cymose branching the terminal bud is active for a short period and becomes modified into some permanent structures like tendrils, thorns of flowers etc. Due to the terminal bud modification the growth of the main stem is definite. This is also called sympodial branching. Further growth in the plant is carried by one or more axillary buds. Cymose branching may be of three types:
- (i) Uniparous or Monochasial type: In uniparous type of branching only one lateral branch is produced at each time below the modified terminal bud. Here the successive lateral branches that are formed unite to form a stem. Such a stem is called false axis or sympodium. The uniparous branching is of two kinds, helicoid and scorpioid.
- (a) **Helicoid branching**: If the successive lateral branches develop on one side it is called helicoid branching. *e.g.*, *Saraca*, *Canna* and *Terminalia*.
- (b) Scorpioid branching: If the successive lateral branches develop on either side alternately, it is called scorpioid branching, e.g., Cissus, Gossypium and Carissa.

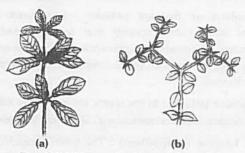

Fig: 2.1-8 Types of uniparous branching (a) Helicoid type branching in *Terminalia* (b) Scorpioid type branching in *Carissa*

- (ii) Biparous or Dichasial type: When the activity of terminal bud stops, further growth of plant takes place by two lateral branches, e.g., Viscum (Mistletoe), Silene, Stellaria, Mirabilis jalapa (Four O' clock), Dianthus (Pink), Carissa carandas (Karonda), etc.
- (iii) Multiparous or Polychasial type: When the activity of terminal bud stops, further growth of plant takes place by a whorl of three or more axillary branches. The axis is said to be multipodial, e.g., Euphorbia tirucalli, Croton, Nerium odoratum (Oleander).

Buds

A bud is a compact undeveloped young shoot consisting of a shoot apex, compressed axis and a number of closely overlapping primordial leaves arching over the growing apex. Buds which develop into flower are called floral buds.

Nature of buds: According to nature they are of following types:

- Vegetative buds: These buds grow to form only leafy shoots.
 - (2) Floral buds: These buds grow to form flowers.
- (3) Mixed buds: They produce both vegetative and floral branches.

Position of buds: They are of following types:

(1) Normal buds: These buds are borne on stems either terminally or laterally. Since they are borne in normal positions, they are called normal buds.

Apical buds: They are borne at the apex of the main stem or a branch. They are also called terminal buds. Cabbage is a large apical bud.

Lateral buds: The buds, which are borne in any other place except at the apices of main stem and its branches, are called lateral buds.

- (i) Axillary buds: The buds develop in the axil of leaves and produces branches.
- (ii) Accessory buds: They are additional buds borne at the leaf bases. Accessory buds are of two kinds.
- (a) Collateral buds: Present on the side of axillary bud e.g., lilies
- (b) Superposed buds: Present above the axillary bud e.g., Aristolochia.
- (iii) Extra-axillary Buds: These buds develop on the node but outside the leaf base.
- (vi) Adventitious buds: When a bud grows from a position other than normal, it is called adventitious bud. Adventitious bud may be:
- (a) Foliar buds: Appearing on leaves e.g., in Bryophyllum, Begonia, Kalanchoe.
- (b) **Radical buds**: Developing on roots e.g., *Ipomea batatus* (sweet potato), Dalbergia
 - (c) Cauline buds: Developing on stem e.g., rose.

Bulbils or Specialised buds: Modification of whole buds into swollen structures due to storage of food materials are called bulbils. e.g., In Lilium bulbiferum and Dioscorea bulbifera, the bulbils develop in axil of leaves; in Agave, floral buds of inflorescence transform into bulbils; In Oxalis, they develop just above the swollen roots.

The leaf

The leaf is a green, flat, thin, expanded lateral appendage of stem which is borne at a node and bears a bud in its axil. It is exogenous in origin and develops from the leaf primordium of shoot apex. The green colour of leaf is due to presence of the photosynthetic pigment — chlorophyll which helps plants to synthesize organic food. The green photosynthetic leaves of a plant are collectively called foliage.

Characteristics of leaf

- (1) The leaf is a lateral dissimilar appendage of the stem.
- (2) A leaf is always borne at the node of stem.
- (3) The growth of leaf is limited.
- (4) The leaves do not possess any apical bud or a regular growing point.

Parts of a typical leaf

The leaf consists of three parts namely, leaf base (usually provided with a pair of stipules), petiole and leaf blade or lamina.

- (1) Leaf base (Hypopodium): Leaf base is the lower most part of the leaf meant for attachment. It acts as a leaf cushion. Some times leaf base shows different variations as follows:
 - (i) Pulvinus leaf base: In members of leguminosae the leaf
- base is swollen. Such swollen leaf bases are called pulvinus leaf bases as seen in mango leaves. It helps in seismonastic movements (e.g., Mimosa pudica) and nyctinastic movements (e.g., Enterobium, Arachis, Bean).
- (ii) Sheathing leaf base: In grasses and many monocots, the leaf base is broad and surrounds the stem as an envelope, such a

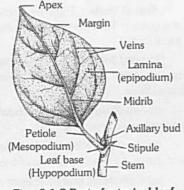

Fig: 2.1-9 Part of a typical leaf

leafbase is called sheathing leaf base. e.g., Sorghum, Wheat and Palms. In grasses (Sorghum, Wheat etc.) the sheathing leaf base protects the intercalary meristem.

- (iii) Amplexicaul: Leaf base completely encircles the stem. e.g., Polygonum.
- (iv) Modified leaf base: The leaf bases in few plants perform accessory functions and show modifications. In Allium cepa (Onion), the leaf bases store food materials and become fleshy. In Platanus and Robenia, the leaf bases protect the axillary buds and grow around them to form cup like structures.
- (v) Stipule: The stipules are the small lateral appendages present on either side of the leaf base. They protect the young leaf or leaf primordia. Leaves with stipules are called stipulate and those without them are called exstipulate. The stipules are commonly found in dicotyledons. In some grasses (Monocots) an additional outgrowth is present between leaf base and lamina. It is called ligule. The leaves having ligules are called ligulate.

Types of stipules : Depending upon the structure and position various kinds of stipules are recognized.

Free lateral stipules: A pair of freely arranged stipules present on either side of the leaf base are called free lateral stipules, e.g., Hibiscus and Cotton.

Adnate stipules: The two stipules that fuse with the leaf base or petiole on either side are called adnate stipules, e.g., Arachis and Rose.

Inter petiolar stipules : Stipules present in between the petioles of opposite leaves, e.g., Ixora and Hamelia.

Axillary stipules : Stipules present in the axil of a leaf are called axillary stipule. These are also called intrapetiolar stipule, e.g., Tabernamontana and Gardenia.

Ochraceous stipules: Membranous tubular stipules that ensheath the axillary bud and a part of internode is called ochraceous stipule. It is formed by the union of two stipules, e.g., Polygonum and Rumex.

Hairy stipules: These are hair like stipules which are dry in nature, e.g., Anacampsora.

Foliaceous: Green, expanded, leaf like stipules are called foliaceous stipules. They carryout photosynthesis, hence called assimilatory stipules, e.g., Pisum sativum and Lathyrus aphaca.

Spinous: In some plants the stipules are modified into hard, pointed defensive organs called spines, e.g., Acacia arabica, Prosopis juliflora and Zizyphus.

Convolute or Bud scales: Scales which protect the buds are called bud scales. Sometimes they are modified into stipules. The bud scales fall off as the buds open, e.g., Artocarpus and Ficus.

(2) Petiole (Mesopodium): A petiole or leaf stalk is a cylindrical or sub cylindrical structure of a leaf which joins the lamina to the base. A leaf with a petiole is called petiolate and the one without it is called sessile.

Modification of petiole

Winged petiole: Green, flattened petioles may be called winged petioles, e.g., Citrus and Dionaea.

Tendrillar petiole: In few plants the petioles are modified into tendrils and helps the plant in climbing. e.g., Clematis and Tropaeolum.

Leaf like petiole (Phyllode): A modified petiole which is flat, green and lamina like is called phyllode. It is a photosynthetic organ. e.g., Acacia auriculaeformis (Australian babool).

Swollen or Spongy petiole: Sometimes the petiole becomes swollen and spongy due to the development of aerenchyma. This type of petioles encloses much air and helps the plant to float. It is a hydrophytic adaptation *e.g.*, *Trapa bispinosa* and *Eichhornia*.

Spinous petiole: In few plants, the leaf blades fall off and the petioles become hard and spinous *e.g.*, *Quisqualis* (Rangoon creeper).

(3) Lamina (Epipodium): The green expanded portion of the leaf is called the lamina. It performs vital functions like photosynthesis and transpiration.

UNIVERSAL BOOK DEPOT 196

Shape of lamina: It varies in different plants as follows.

(1) Acicular type	(2) Linear type
Needle shaped leaves.	Long and slightly broader leaves.
e.g., Allium cepa, Pinus Pinus	e.g., Triticum (wheat), Oryza sativa Grass
(3) Lanceolate type Lance shaped leaves. e.g., Nerium, Polyalthea. Nerium	(4) Orbicular or Rotund type More or less circular leaves. e.g., Lotus, Nasturtium Lotus
(5) Elliptical oval type Leaves are like an ellipse. e.g., Psidium (Guava), vinica Vinca	(6) (i) Ovate type Egg or top shaped leaves. e.g., China rose (ii) Obovate type Inverted egg shaped. e.g., Juglans regia (Walnut), Prunus amygdalus (badam)
(7) Spathulate Spoon like leaves. e.g., Drosera, Calandula Euphorbia	(8) Oblique type Leaf lamina is with unequal half. e.g., Margosa Margosa
(9) Oblong type Rectangular leaves. e.g., Banana Banana	(10) Reniform type Kidney shaped leaves. e.g., Hydrocotyle Hydrocotyle
Heart shaped (with a deep notch at the base) leaves. e.g., Betel, Banyan (ii) Obcordate type Inverted heart shaped. e.g., Oxalis, Bauhina	(12) Saggitate type Leaves shaped like an arrow head. e.g., Sagittaria Sagittaria
Leaves like saggitate but the two basal lobes are directed outwards. Le.g., Ipomoea.	(14) Lyrate type Leaves shaped like a lyre. e.g., Raphanus sativus (Raddish), Brassica campestris (mustard) Mustard
Hollow and cylindrical leaves. e.g., Onion Onion	(16) Cuneate type Wedge shaped leaves. e.g., Pistia

Margin of lamina: The margin of the lamina may be of different types as given.

Entire Leaves with smooth margin.	Serrate Leaves have saw like margin.	Repand Leaves have wavy margin.	Dentate Leaves have large pointed teeth like margin.	Crenate Leaves have round teeth margin.	Spiny Leaves have spiny margin.	Margins have incisions which are further incised.
Mango	Hibiscus	Polyalthia	Aloe	Bryophyllum	Argemone	Ricinus

Apex of lamina: The apex of the leaf lamina shows variations in different plants.

1) Acute The apex is narrow and pointed. e.g., Mango. China rose	(2) Acuminate The apex is drawn out into a long tapering tail. e.g., Ficus religiosa.
(3) Obtuse The apex is rounded. e.g., Banyan.	(4) Mucronate Round apex with sharp pointed tip. e.g., Vinca.
(5) Cuspidate or Spiny The apex is spinous. e.g., Date palm.	(6) Tendrillar The apex form a tendril. e.g., Gloriosa.
(7) Cirrhose The mucronate like apex ends with fine thread like structure. e.g., Banana.	(8) Truncate The shape is abruptly cut across. e.g., Paris polyphylla.
(9) Retuse The apex obtuse is partial e.g., Pistia	(10) Emarginate The obtuse apex is deeply notched. e.g., Bauhinia, Oxalis.

Surface of lamina: The surface of the lamina may be of many kinds.

Glabrous: Smooth and without hair. e.g., Mangifera indica.

Glaucus: Covered by waxy coating with white tinge. e.g., Calotropis.

Scabrous: Rough surface. e.g., Ficus.

UNIVERSAL BOOK DEPOT 1960

Viscose: Sticky surface. e.g., Cleome.

Pubescent: Covered with soft and wooly hair. e.g., Tomato.

Pilose: Covered with long distinct scattered hair. e.g., Grewia pilosa.

Hispid: Covered with long rigid hair. e.g., Cucurbita.

Spinose: Covered with small spines. e.g., Solanum xanthocarpum.

Texture of lamina : The texture of lamina also varies in different species.

Herbaceous: When the lamina is thin and soft.

Coriaceous: When the lamina is leathery.

Succulent: When the lamina is thick, soft and juicy.

Hygrophytic: When the lamina is very thin, membranous and spongy.

Life Span or Duration

- (i) **Caducous** (Fugacious): Leaves falling down soon after their appearance, e.g., Opuntia (vern. Chhittar Thor).
- (ii) **Deciduous or Annual :** Leaves falling off almost simultaneously at the and of growing season. The phenomenon is called **leaf fall**, e.g., Mulberry, Poplar. In *Euphorbia royleana* the leaves are **drought deciduous**.
- (iii) Persistent (evergreen): Leaves live for more than one season. They fall down individually at different times. Plants look evergreen, e.g., Pinus, Eucalyptus, Mango, Oleander.

Leaf Insertion

- (i) **Radical**: Leaves borne on a reduced stem and appear to arise directly from the top of the root, e.g., Radish, Turnip.
- (ii) Cauline: Leaves found on the nodes of the main stem, e.g., Maize, Rose, Althaea.
- (iii) Ramal: Leaves produced on the nodes of the stem branches, e.g., Dalbergia, Peepal, Zizyphus.

Types of leaves

On the basis of shape of lamina, the leaves are classified into two types, namely, simple leaf and compound leaf.

- (1) **Simple leaves:** The leaf having single undivided lamina is called the simple leaf. The simple leaf may be entire (e.g., Mango and *Hibiscus rosa sinensis*) or lobed. The lobes of a simple leaf may be entire pinnately arranged (e.g., Brassica) or palmately arranged (e.g., Gossypium, Passiflora and Ricinus).
- (2) Compound leaves: A compound leaf is one in which the lamina or the leaf blade is completely divided into many segments or units called leaflets or pinnae. When pinnae of leaflets are attached in various ways to the portion of leaf axis known as the rachis. The compound leaves may be of two types, namely, pinnate compound leaves and palmate compound leaves.
- (i) **Pinnate compound leaves:** It is the most familiar and widespread type of compound leaf in which the rachis is elongated and bears two rows of simple or divided leaflets. The leaflets may be arranged alternately or in pairs along with the rachis. It is of following types:

Unipinnate compound leaf: Here the primary rachis is unbranched and bear leaflets on either side. Unipinnate leaves are of two types:

Paripinnate: The unipinnate leaf with even number of leaflets. They are borne in pairs. e.g., Tamarindus indica (Imli), Cassia etc.

Imparipinnate: The unipinnate leaf with odd number of leaflets. The rachis is terminated by single unpaired leaflet. e.g., Neem, Rose, Murraya.

Bipinnate compound leaf: In this type, the primary rachis is divided once and produce secondary rachis. The leaflets develop on the secondary rachis. *e.g.*, *Delonix* and *Acacia*, *Mimosa pudica*, *Albizzia* (sub family mimosoideae).

Tripinnate compound leaf: In this type the primary rachis divides twice and produces secondary and tertiary rachii. The leaflets develops on the tertiary rachii. e.g., Moringa (Soanjana) and Millingonia.

Decompound leaf: Here the primary rachis divides many times without any definite order. The lamina is dissected into many units. e.g., Coriandrum, Carrot etc.

(ii) **Palmate compound leaf:** In a palmately compound leaf, the leaflets are arranged at the tip of the petiole. According to the number of leaflets present at the tip of the petiole. These leaves are of following types:

Unifoliate: In this case, a palmately compound leaf is reduced to a single terminal leaflet. e.g., Citrus (Khatta), Lemon, etc.

Bifoliate: This type of leaf has only two leaflets attached side by side at the tip of petiole, e.g., Balanites roxburghii, Hardwickia binata, etc.

Trifoliate: This type of leaf has three terminal leaflets, *Aegle marmelos* (Wood apple, Vern, Bael), *Oxalis corniculata*, *Trifollium* (Clover), etc. These leaves differ from trifoliate imparipinnate (e.g., *Lablab*) in having all the three leaflets attached at the tip of petiole.

Quadrifoliate: This leaf has four leaflets attached to the tip of petiole. e.g., Paris quadrifolia, Marsilea.

Multifoliate (Digitate): A palmately compound leaf having five or more terminal leaflets, e.g., Bombax malabarica, Cleome viscosa, Gynandropsis pentaphylla, etc.

Phyllotaxy (Phyllotaxis)

The arrangement of leaves on the stem is called phyllotaxy (Gk. *Phyllon* = leaf; taxis = arrangement).

(1) Alternate or Spiral phyllotaxy: When only one leaf is found at each node. The leaves present at successive nodes alternate with each other. The arrangement is said to be alternate or spiral. The leaves are commonly arranged spirally around the stem. In spiral phyllotaxy, the leaves are arranged on the stem in regular vertical row. Such rows are called orthostichies. In practice the angular divergence is determined in the following manner:

Angular divergence =
$$\frac{\text{No. of circles}}{\text{Orthostichies}}$$
 of a circle *i.e.*, 360°

A phyllotaxy is written by taking the number of spirals (circles) as numerator and the number of leaves as denominator. Based on the number of orthostichies seen on the stem, the spiral phyllotaxy may be described as given under.

Distichous or 1/2 Phyllotaxy : Where the angular divergence is 1/2 of 360° i.e., 180°. e.g., Ravenella.

Tristichous or 1/3 Phyllotaxy: Where the angular divergence is 1/3 of 360° i.e., 120°. e.g., Moss, Cyperus rotundus.

Pentastichous or 2/5 Phyllotaxy: Where the angular divergence is 2/5 of 360° i.e., 144°. e.g., China rose.

Octastichous or 3/8 Phyllotaxy: Where the angular divergence is 3/8 of 360° i.e., 135°. e.g., Carica papaya.

In these types, if one adds up two preceeding numerators and denominators, a series is formed called Schimper-Brown Series.

e.g.,
$$\frac{1}{2}$$
, $\frac{1}{3}$, $\frac{1+1}{2+3}$ = $\frac{2}{5}$, $\frac{1+2}{3+5}$ = $\frac{3}{8}$, $\frac{2+3}{5+8}$ = $\frac{5}{13}$, and so on.

- (2) Opposite phyllotaxy: When two leaves are present at a node opposite to each other the type of phyllotaxy is called opposite. It is of two types:
- (i) Opposite superposed: All the pair of leaves of a branch arise in the same plane so that only two vertical rows of leaves are formed. e.g., Jamun, Guava, etc.
- (ii) Opposite decussate: A pair of leaves at one node stands at right angle to the next upper or lower pair so that four vertical rows are formed on the stem. e.g., Calotropis, Zinnia, Tulsi, Quisqualis.
- (3) Whorled phyllotaxy: If more than two leaves are present at a node as whorl, it is called whorled phyllotaxy. It is also called cyclic or verticellate phyllotaxy. e.g., Nerium, Hydrilla and Alstonia.
- (4) **Leaf mosaic**: This is a special type of arrangement of leaves. Older leaves present at the lower nodes of the stem possess longer petioles with bigger lamina and the young leaves of upper nodes bear shorter petioles with smaller lamina. e.g., Begonia, Acalypha and Sycamore.

Vernation (Aestivation)

Arrangement of leaves in bud condition is known as vernation e.g., Imbricate (irregular overlapping), contorted (twisted, regular overlapping of margins), induplicate (margin bent inwardly), equitant (conduplicate in two series, one overlapping the other completely), half equitant, supervolute (convolute leaves, one rolled over other).

Heterophylly

It is the occurrence of more than one type of leaves on the same plant. Heterophylly is of four types:

- (1) Adaptive heterophylly: Submerged leaves are different from floating and emerged leaves of the same plant due to different adaptations. e.g., Limnophila, Heterophylla, Sagittaria, Ranunculus aquatilis. The emerged leaves are broad and fully expanded while the submerged leaves are narrow, ribbon shaped, linear or highly dissected.
- (2) Environmental heterophylly: The heterophylly is due to change in environment including soil, temperature, humidity and air currents. e.g., Sagittaria.
- (3) **Developmental heterophylly**: Young leaves are different from mature leaves, e.g., Eucalyptus.

(4) Habitual heterophylly: Leaves of different shape and incisions occur at the same time, e.g., Jack fruit tree (Artocarpus heterophyllus), Ficus heterophylla, Hemiphragma heterophyllum, Broussonetia papyrifera. In Hemiphragma, the main stem bears ovate and entire leaves while branches possess acicular leaves.

Modification of leaves

Leaf tendrils: The leaves are modified into slender wiry and coiled structures called leaf tendrils. The tendril may be formed by entire leaf or a part of the leaf.

Entire leaf modified into tendril, e.g., Lathyrus aphaca (Wild pea).

Terminal leaflets modified into tendril, e.g., Pisum sativum (Pea), Lathyrus odoratus (Sweet pea), Narvella.

Leaf tip modified into tendril, e.g., Gloriosa.

Petiole modified into tendril, e.g., Clematis.

Stipule modified into tendril, e.g., Smilax.

Midrib modified into tendril, e.g., Nepenthes.

Spines: A pointed structure formed by the modification of entire leaf or part of a leaf is called a spine. Different part of a leaf or entire leaf may be modified into spines. e.g., In *Opuntia* leaves of axillary branches are modified into spines.

In Berberis entire leaf is modified into three spines. In Phoenix leaf tip is modified into spine. In Citrus first leaf of axillary branch modified into spine. In Argemone leaf margin is modified into spine. In Perkinsonia, Acacia and Zizyphus stipules are modified into spines.

Scale leaves: In many xerophytes, the foliage leaves are reduced to scale leaves. They are thin, membranous, dry, small, sessile, colourless structures. e.g., Casuarina, Orobanche and Balanophora.

Phyllode: It is a green, expanded structure formed by the modification of petiole or rachis of leaf. Many xerophytes reduce the size of their leaves to minimize water loss. Such plant develop phyllodes to carryout photosynthesis e.g., Acacia, Melanoxylon and Parkinsonia.

Storage leaves: Leaves become fleshy due to storage of water or food materials. Such leaves are called storage leaves. They are usually found in succulent plants. In plants like Aloe, Allium, Kalanchoe and Peperomia.

Reproductive leaves: In some plants the vegetative propagation is carried out by the production of epiphyllous buds on leaves. Such leaves are called reproductive leaves. The epiphyllous buds when come in contact with soil develop into new plants.

Absorbing leaves : In some rootless, aquatic plants, the submerged leaves are modified into root like structure to absorb water and mineral salts. Such modified leaves are called absorbing leaves. e.g., Utricularia.

Floral leaves: Floral parts such as sepals, petals, stamens and carpels are modified leaves. Sepals and petals are leafly stamens are considered pollen bearing microsporophylls and carpels are ovule bearing megasporophylls.

Cotyledons: The mature embryo shows either one (monocotyledons) or two cotyledons (dicotyledons). Cuscuta, a

parasite is included in dicotyledon. However it has no cotyledon and many cotyledons, as in gymnosperms. These cotyledons are considered as embryonic leaves which are the first leaves of a shoot system.

Trap leaves: The trap leaves are also called insectivorous leaves or carnivorous leaves. Plants having trap leaves usually grow in nitrogen-deficient soils (boggy soils). They have poorly developed root system.

These plants get their nitrogenous requirement by capturing the insects. To attract, capture, kill and digest the insects, the leaves are modified into trap leaves. e.g., Nepenthes.

Leaf Bladders: Some of the leaf segments of aquatic insectivore, *Utricularia*, are modified into bladders for trapping small aquatic animals like *Cyclops*.

Leaf Pitcher: Lamina (e.g., Nepenthes) or whole leaf (e.g., Dischidia, Sarracenia) is modified into pitcher. Pitcher has lid and takes part in catching and digesting small animals in Nepenthes and Sarracenia. In Dischidia the pitcher stores rain water.

Leaf Fall or Leaf Abscission: It is the shedding of leaves. A special layer of parenchymatous cell appears at the base of leaf. The same is called abscission or separation layer. A layer of suberised thick walled cells (cork cells) is formed below it. It is protective layer. The cells of abscission layer gelatinise and the leaf falls leaving a scar.

Venation

The arrangement of veins in the lamina of a leaf is called venation. The veins are the hard structures consisting of xylem and pholem. The veins give mechanical strength and shape to the lamina. Angiosperms exhibit two types of venation.

(1) Reticulate venation

In this type, the lateral veins divide and redivide to form many veinlets. These veinlets are arranged in a net like fashion or reticulum. Reticulate venation is the characteristic feature of dicotyledons. But exceptionally some monocotyledons also show reticulate venation. e.g., Smilax, Alocasia and Dioscorea etc. Reticulate venation is of two types:

- (i) Unicostate or Pinnate venation: This type of venation is characterized by the presence of a single strong midrib that extends upto the apex of lamina. The midrib produce lateral veins on either side which divide repeatedly. e.g., Ficus and Mangifera.
- (ii) Multicostate or Palmate venation: Here more than one prominent veins start from the base of the lamina and proceed upwards.

The lateral veinlets, arising from main veins, form network. Multicostate venation is of two types :

- (a) **Convergent**: When the prominent veins converge towards the apex of lamina. *e.g.*, *Zizyphus* and *Cinnamonum camphora* (kapoor), etc.
- (b) **Divergent**: When the prominent veins spread out towards the margins. e.g., Papaya, Ricinus, Cucurbita etc.

(2) Parallel or Striate venation

In this type, veins and veinlets run parallel to each other. Parallel venation is the characteristic feature of monocotyledons.

Exceptionally few dicots show parallel venation, e.g., Calophyllum and Eryngium. It is of two types:

- (i) Unicostate or Pinnate venation: The leaf lamina possesses single prominent vein which gives rise to a large number of lateral veins. All the lateral veins run parallel towards margin. e.g., Banana, Canna, Curcuma etc.
- (ii) Multicostate or Palmate venation: The leaf lamina possesses several prominent veins which run parallel to each other. It is of two types:
- (a) **Convergent**: The prominent veins run parallel to each other and converge at the apex. *e.g.*, Sugarcane, Maize, Wheat, Bambooes and Grasses.
- (b) Divergent : All the prominent veins of leaf lamina spread out towards the margin. e.g., Fan palm.

Ptyxis: Folding of lamina in bud condition is called ptyxis – circinate (rolled from apex to base, e.g., fern leaves), plicate (plaited, folded lengthwise like Japanese fan, e.g., Fan Palm), conduplicate (folded over midrib, e.g., Bauhinia, Guava), reclinate (upper half bent over lower half e.g., Loquat), crumpled (irregular folding, e.g., Cabbage), involute (margins rolled on upper surface, e.g., Colocasia), revolute (margins rolled on lower surface, e.g., Oleander).

Inflorescence

The flowers are arranged in some definite manner on the plant in each species of the flowering plants. The mode of arrangement of flowers on a specialised branch on top of the plant which bears flowers is called inflorescence. The stalk of the inflorescence is called peduncle.

- (1) Solitary flowers: They are those flowers which are not grouped into inflorescence but occur singly. Solitary flowers are of two types:
- (i) **Solitary terminal**: Single terminal flowers develop on the tip of main stem and its branches, e.g., Poppy
- (ii) **Solitary axillary:** Flower occurs singly in the axil of a leaf (e.g., Petunia) or tip of a peduncle (e.g., China Rose = Shoe Flower = Hibiscus rosa-sinensis).
- (2) Racemose Inflorescence: An inflorescence of indefinite or indeterminate growth having lateral or axillary flowers borne acropetally (oldest at base and youngest at apex). Different types of racemose inflorescence are as follows:

(a) Simple Racemose Inflorescence

- (i) **Typical Raceme** (= **Raceme**) : Unbranched, elongated peduncle bearing pedicellate or stalked flowers acropetally, e.g., Delphinium (Larkspur), Raphanus (Radish), Linaria, Lupinus.
- (ii) **Corymb**: All the acropetally arranged flowers come to lie at the same level due to slight shortening of peduncle and slight elongation of pedicels of lower flowers, *e.g.*, *Iberis*, *amara* (Candytuft).
- (iii) Corymbose-Raceme: Like a corymb near the growing point and raceme lower down though the pedicels of the lower flowers are longer, e.g., Brassica compastris (Mustard).

- (iv) Umbel: Pedicellate flowers arranged centripetally around an extremely reduced peduncle with an involucre below, e.g., Centella (= Hydrocotyle) asiatica (Brahmi Booti), Androsace.
- (v) **Spike**: Sessile (i.e., without stalk) flowers borne acropetally, e.g., Callistemon (Bottle Brush), Amaranthus, Achryanthes, Adhatoda.
- (vi) Spikelet: It is a compact spike having a few flowers borne on axis called rachilla and surrounded by two scales (= bracts) called glumes, e.g., Wheat, Oat, Sorghum, Grass.
- (vii) **Strobile:** It is a spike having persistent and membranous bracts, e.g., Humulus (Hop).
- (viii) Catkin: Compact unisexual spike often hanging, e.g., Morus (Mulberry), Salix (Willow), Populus (Poplar), Betula (Birch), Acalypha, Quercus (Oak).
- (ix) Spadix: A fleshy spike covered with spathe is called spadix. e.g., maize, banana etc.
- (x) Capitulum (Racemose Head, Anthodium): Peduncle is flattened to form receptacle that bears centripetally arranged sessile flowers or florets surrounded by involucre of bracts, e.g., Cosmos, Zinnia, Tagetes, Chrysanthemum, Sonchus, Ageratum. Florets may be tubular or ligulate. Capitula may be homogamous (with one type of florets e.g., only ligulate in Sonchus or Zinnia and only tubular in Vernonia or heterogamous (with two type of florets). Sunflower (Helianthus annuus) is heterogamous with both ligulate female ray florets and tubular intersexual disc florets.

(b) Compound Racemose Inflorescence

- (i) Raceme of Racemes (= Compound Raceme = Panicle): Racemes are borne acropetally on a raceme, e.g., Cassia fistula, Delonix regia, (Gold Mohar), Caesalpinnea (Gulmohar), Yucca, Asparagus, Asphodelus, Margosa.
- (ii) Corymb of Corymbs (= Compound Corymb): An axis bearing a number of corymbs in a corymbose fashion, e.g., Pyrus, Cauliflower. Marketed Cauliflower (Brassica oleracea var. botrytis) represents an undeveloped inflorescence.
- (iii) Umbel of Umbels (= Compound Umbel): Many umbels develop from a common point in an umbellate fashion. It is characteristic of family umbelliferae. Involucre (below mother umbel) and involucels (below each umbellule) may be present, e.g., Coriander, Fennel, Carrot, Cumin.
 - (iv) Spike of Spikes: e.g., Amaranthus spinosus.
 - (v) Spike of Spikelets: e.g., Wheat
- (vi) Spadix of Spadices (Compound Spadix): e.g., Date Palm, Coconut
 - (vii) Capitulum of Capitula: e.g., Echinops.
 - (viii) Panicle of Spikelets: e.g., Jowar, Rice, Oat.
- (3) Cymose Inflorescence: A more or less flat topped, broad inflorescence of determinate growth or definite growth. Where central flower opens first (i.e., central flower is most mature). Here the main axis terminates in a flower.
- (a) Uniparous or Monochasial Cyme: The flowering axis is sympodial. As the growing point ends in a flower, further growth is continued by a lateral branch which also ends in a flower. The process is repeated.

- (i) **Helicoid Uniparous**: The flowers are borne on one side *e.g.*, Begonia, Drosera (sundew). It can be drepanium (flower in one plane) or bostryx (flower in different planes).
- (ii) **Scorpioid Uniparous**: The flowers are borne on both sides alternately, e.g., *Tecoma*, *Freesia*, *Heliotropium*, **Rhipidium** is scorpioid cyme having all the flowers in one plane (e.g., *Solanum nigrum*) while in cincinnus the flowers are borne in different planes.

Solitary axillary flower of China Rose is also considered to be single flowered uniparous cyme.

- (b) **Biparous or Dichasial Cyme**: Growth of the flowering axis is continued by two branches when the growing point of the parent axis is changed into a flower, e.g. Dianthus (Pink), Silene, Nyctanthes, Jasminum, Clerodendron, Bougainvillea, Teak. Arrangement of flowers is either **basipetal** (if axis elongated) or **centrifugal** (if axis short).
- (c) Multiparous or Polychasial Cyme: More than branches continue growth of the flowering axis when the parent axis is changed into a flower, e.g., Calotropis, Hamelia, Asclepias, Arrangement of flowers is generally centrifugal.
- (d) Cymose Head: A number of centrifugally arranged flowers are borne around a receptacle, e.g., Anthocephalus cadamba (Kadam). Acacia, Mimosa and Albizzia also possess such an inflorescence but it is now considered to be capitate or spikate head due to centripetal arrangement of flowers.
- (e) Scapigerous Cyme Umbel: In Onion, a scape bears and umbellate cyme covered by one or more spathes.

(4) Mixed Inflorescence

- (i) **Thyrsus** (**Thyrse**): Cymose clusters arranged acropetally, e.g., Vitis vinifera (Grape Vine).
- (ii) Mixed Spadix (Spadix of Cymes): Spadices having cymose inflorescence arranged acropetally on fleshy axis, e.g., Banana.
- (iii) Panicle of Spikelets: Spikelets arranged in a compound raceme, e.g., Oat, Rice.
 - (iv) Corymb of Capitula: e.g., Ageratum.
- (v) Other Types: Like umbel of capitula, cyme of capitula (e.g., Vernonia), cyme of umbels (e.g., Lantana), cyme of corymbs, etc.

(5) Special Inflorescence

- (i) **Hypanthodium:** It has a flask-shaped fleshy receptacle, a pore or ostiole lined by scales and a short canal bearing hair. Internally the receptacle bears male flowers ostiole, female flowers towards base and sterile female flowers between the two, e.g., Ficus (Peepal, Banyan, Fig).
- (ii) Coenanthium: It has a saucer-shaped receptacle with upturned margin and bearing florets like hypanthodium, e.g., Dorstena.
- (iii) Verticillaster: It is characteristic inflorescence of Ocimum (Tulsi) of family Lamiaceae or Labiatae. Here flowers are arranged in two opposite cymose groups on each node.
- (iv) **Cyathium**: It is characteristic inflorescence of *Euphorbia*, in which single female flower is present in the centre and number of male flowers around it, inside a cup-shaped involucre (whorl of bracts).

Flower

It can be defined as modified dwarf shoot which is meant for sexual reproduction. It is characteristic feature of angiosperm.

Parts of a typical flower: A typical flower of an angiosperm consists of four types of floral parts namely calyx, corolla, androecium and gynoecium.

General description of a flower

The flowers are termed pedicellate if they possess stalks and sessile if they lack them. The flower may be described as complete if it bears all the floral parts and incomplete, when one or more floral parts are absent. Flowers are called bisexual if they bear both androecium and gynoecium e.g., Hibiscus. The unisexual flowers have either androecium or gynoecium. The unisexual flowers may be male flowers or female flowers. The male flower are also called staminate flowers as they have stamens only.

The female flowers have only the carpels and hence called pistillate flowers. Flowers with sterile sex organs are described as neutral flowers. According to the distribution of male, female and bisexual flowers, various patterns are recognized.

Monoecious : Presence of male and female flowers on the same plant, e.g., Acalypha, Cocos and Ricinus. In maize flower are unisexual but plant is monoecious.

Dioecious: Presence of male and female flowers on different plants, namely, male plants and female plants. e.g., Cycas, Carica papaya and Vallisneria.

Polygamous: Presence of unisexual and bisexual flowers on the same plant, e.g., Mangifera and Polygonum.

Symmetry of flower

The number, shape, size and arrangement of floral organs in a flower determines its symmetry. On the basis of symmetry flowers can be of the following types:

Actinomorphic (Regular = Symmetrical): Actinomorphic flowers can be divided (passing through center) by any vertical plane into two equal and similar halves. e.g., Mustard, Brinjal, Catharanthus roseus.

Zygomorphic (Monosymmetrical) : Zygomorphic flowers can be divided into two equal halves by only one vertical division *e.g.*, Pea, Larkspur, *Ocimum*.

Asymmetrical (Irregular): Asymmetrical flowers can not be divided into two equal halves by any vertical division. *e.g.*, *Canna*, *Orchids*.

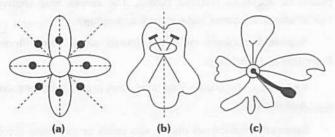

Fig : 2.1-10 Symmetry of flowers (a) Actinomorphic, (b) Zygomorphic, (c) Asymmetrical

Arrangement of floral organs

On the basis of arrangement of floral organs, three types of flowers are recognized. They are :

Acyclic: Here the thalamus is conical or convex and the floral parts are spirally arranged, e.g., Water lily and Magnolia.

Cyclic: Here the floral organs are arranged in regular whorls at the nodes of the thalamus, e.g., Hibiscus and Datura.

Hemicyclic (Spirocyclic): Here some floral parts (sepals and petals) are arranged in regular whorls and the remaining parts (stamens and carpels) are arranged spirally. *e.g.*, *Annona* and *Polyalthia*.

Number of floral parts in whorl is called the merosity. There are two kinds of flowers based on the merosity of the flower. They are isomerous flowers and anisomerous flowers.

If the number of sepals, petals, stamens and carpels of flower is equal, such flowers are called isomerous flowers.

Dimerous: Two floral parts in each whorl. e.g., Poppy flower.

Trimerous: Three floral parts in each whorl. e.g., Monocot flowers (Liliaceae).

Tetramerous: Four floral parts in each whorl. e.g., Mustard.

Pentamerous: Five floral parts in each whorl. e.g., Solanum.

Detailed structure of flower

Angiospermic flowers exhibit many variations in their external morphological characters.

(1) Bract: Bract (hypsophyll) is a small leaf like structure on the peduncle which produces a flower in its axil. The floral buds are usually protected by the bracts.

Flower with a bract is described as bracteate and the flower without a bract is known as ebracteate. Bracteoles are small scale like structures present on the pedicel. Bracts are modified into following structures:

Foliaceous bract: Leaf like, expanded green bract is called the foliaceous bract, e.g., Pisum, Lathyrus, Adhatoda and Gynandropsis.

Spathe: A large modified bract which encloses spadix inflorescence totally or partially. It may be leathery or woody, e.g., *Alocasia, Cocoa, Musa* and *Typhonium*.

Petaloid bract: Brightly coloured petal like bract is known as petaloid bract, e.g., Bougainvillea, Poinsettia and Euphorbia.

Involucre: One or more whorls of green bracts that protect young inflorescence is called involucre, e.g., Coriandrum, Tagetes and Heracleum.

Epicalyx: Whorl of bracteoles present below the calyx or outside the calyx, e.g., Hibiscus rosa sinensis and Malvaviscus arborcus.

Scaly bracts: Reduced, membranous, scale like bracts seen in head inflorescence, e.g., florets in *Tridax* and *Helianthus*.

Glumes: The bracts found on the rachilla of spikelet are called glumes. They may be sterile glumes or fertile glumes (lemma), e.g., Oryza sativa.

(2) **Thalamus**: The terminal part of the pedicel is called thalamus or torus or receptacle. It is a condensed axis of the flower from which all floral parts arise. Depending upon the position of gynoecium on the thalamus with respect to other parts, flowers are of three kinds – hypogynous, perigynous and epigynous.

In many flowers, the thalamus is condensed and the internodes are not seen clearly. But there are some flowers with elongated, distinct floral internodes as mentioned below:

Anthophore: This is the first elongated internode between the calyx and corolla, e.g., Silene, Pennsylvania and Lychnis.

Androphore: It is the second elongated internode between corolla and androecium, e.g., Gynandropsis.

Gynophore: It is the third elongated internode between androecium and gynoecium e.g., Capparis and Gynandropsis.

Gynandrophore: It is an elongated stalk like part between non essential and essential organs of the flower. It is equivalent to androphore, e.g., Passiflora.

Carpophore: This is a stalk like connection present between two carpels. It is formed due to expansion of the thalamus between the carpels, e.g., Coriandrum and Foeniculum.

Androgynophore: When androphore and gynophore are present simultaneously, it is called androgynophore *e.g.*, in *Cleome gynandra Syn. Gynandropsis gynandra*.

(3) Perianth: The non essential organs, calyx and corolla are together called perianth. The perianth protects the stamens and carpels. In angiospermic flowers, the perianth exists in different forms.

Achlamydeous: Perianth is absent and the flowers appear naked. Mostly the achlamydeous flowers occur in cyathium inflorescence. e.g., Euphorbia, Poinsettia.

Chlamydeous: Perianth is present and the flowers usually appear attractive. The chlamydeous flowers are of two types. They are:

Monochlamydeous flowers are with perianth in one whorl, e.g., Amaranthus and Ricinus.

Dichlamydeous flowers are with perianth differentiated into calyx and corolla. They are arranged in two different whorls. The dichlamydeous condition is of two types:

Homochlamydeous: The two whorl or the perianth (calyx and corolla) are similar in all respects and are not identified by different colours, e.g., Michelia.

Heterochlamydeous: The two whorls of the perianth are dissimilar in many respects. The outer whorl consists of small, green sepals and the inner whorl with large variously coloured petals, e.g., Datura and Hibisus. The term "tepals" is used to describe the perianth units when both sepals and petals are similar. e.g., most of the monocots.

(4) Calyx: It is the outermost whorl of the flower. It consists of sepals. Usually, the sepals are small and green. They protect other floral organs when the flower is in bud condition. The calyx is described as polysepalous when the sepals are free (e.g., Annona, Tomato) and gamosepalous when the sepals are united (e.g., Datura and Hibiscus). If sepals are fused less than half of the length of calyx tube it is called as partite and if the fusion of sepals is very little, just at the base of calyx tube, it is said to be connate. The sepals may be deciduous or persistent.

Usually the persistent calyx do not show any growth after fertilization. Such a calyx is termed as marcescent (e.g., Brinjal, Chilies). Sometimes the persistent calyx shows continuous growth even after, fertilization. This type of calyx called acrescent (e.g., Physalis and Shorea).

In some plants a whorl of green sepals like structure is present at the base of calyx called epicalyx. Epicalyx is considered a whorl of the bracteoles and mostly found in the flowers of family Malvaceae (Althaea, Cotton). The calyx may show number of modifications. They are:

Campanulate: Bell shaped, e.g., Althaea.

Cupulate: Cup like, e.g., Gossypium.

Urceolate: Urn shaped, e.g., Hyoscyamus.

Infundibuliform: Funnel shaped, e.g., Atropa belladona.

Tubular: Calyx tube like, e.g., Datura.

Bilabiate: Calyx forms two lips, e.g., Ocimum.

Spurred: One or two sepals forming a beak like structure, e.g., Larkspur.

Pappus : Calyx are modified into hairs e.g., Sonchus, Tridax (Asteraceae/Compositae).

Spinous: When calyx forms spines, e.g., Trapa.

Hooded: When sepals enlarged to form a hood over the flower, e.g., Aconitum.

Petaloid: Enlarged and brightly coloured sepals, e.g., Clerodendron, Mussaenda, Sterculia, Caesalpinia and Saraca.

(5) Corolla: It is the second whorl of the flower consisting of petals. Usually the petals are brightly coloured and scented. They attract the insects which act as agents for pollination. The corolla may be polypetalous (with free petals), gamopetalous (with united petals) or apetalous (without petals). The corolla may undergo modifications or possess some special appendages.

Sepaloid: Green or dull coloured sepals. e.g., Anona, Polyalthia and Artabotrys.

Saccate: The corolla tube may form a pouch on one side. e.g., Antirrhinum.

Spurred: Sometimes one or two petals or the entire corolla tube grow downwards forming a spur that usually stores nectar. e.g., Aquilegia vulgaris.

UNIVERSAL BOOK DEPOT 1960

Corona: Special appendages of different kinds like scales, hairs develop from the corolla. Such appendages are called corona. e.g., Passiflora, Oleander and Nerium.

Forms of corolla: Both polypetalous and gamopetalous corolla exhibit great variation in their forms. It is of following types:

(i) Polypetalous corolla: They are of following types:

Cruciform: Four free clawed petals arranged in the form of a cross, e.g., Mustard and Radish.

Rosaceous: Five free sessile petals with lobes spreading outwards, e.g., Rose, Hibiscus.

Caryophyllaceous: Five free clawed petals with limbs at right angles to the claw, e.g., Dianthus.

Papilionaceous: Five free unequal petals arranged in definite fashion. The posterior petal is the largest and is called standard or vexillum. On either side of the standard, two lateral petals called wings are present. The remaining two anterior petals unite to form a boat shaped structure called the keel. e.g., plants of family papilionaceae.

(ii) Gamopetalous corolla: They are of following types:

Tubular: Five united petals form a cylindrical tubular structure, e.g., disc florets of Asteraceae.

Infundibuliform: It is a funnel shaped corolla, e.g., Datura.

Campanulate: It is bell shaped corolla, e.g., Thevetia.

Rotate: Short tubular corolla with spread out lobes appearing like a wheel e.g., Brinjal.

Hypocrateriform: It is a salver shaped corolla. It is provided with a elongated narrow tube having lobes at the top placed at right angles, e.g., Vinca.

Ligulate: Corolla with a short tube which is drawn out into a tongue shaped structure e.g., ray florets of Asteraceae.

Bilabiate: The irregular corolla is united, in such a way that it appears two lipped. It is the characteristic corolla of labiatae, e.g., Leucas.

(6) Aestivation: The arrangement of sepals and petals in bud condition of the flower is called "aestivation". It may be of following types:

Open: If the margins of perianth members in a whorl are free with wide gap between them, then the type of aestivation is called 'open', e.g., sepals of Mustard.

Valvate: Here the edges of perianth members in a whorl are very nearly touching each other but do not overlap, e.g., calyx and corolla in *Annona*.

Twisted: In this type, the perianth members of a whorl show one edge outside and one edge inside. Thus they regularly overlap the neighbouring members on one side. The twisted aestivation is also called contorted or convolute aestivation, e.g., corolla of *Hibiscus*.

Imbricate: Here in a whorl of perianth members, one is completely inside and another is completely outside. The remaining perianth members show one edge inside and the other edge outside. The imbricate aestivation is of two types, namely, descending imbricate and ascending imbricate.

Descending imbricate: Here the odd petal is posterior and completely outside. The anterior pair of petals are completely inside. The remaining petals show regular overlapping in the descending manner. e.g., Tephrosia, Crotalaria and Dolichos.

Ascending imbricate: Characteristic of corolla of family Caesalpiniaceae. Here the odd petal is posterior and completely inside. One of the anterior petals is completely outside. The remaining petals show regular overlapping in ascending manner, e.g., Cassia and Delonix.

Quincuncial: In this type, out of the five perianth members in a whorl two are completely outside, two are completely inside and the remaining has one edge outside and one-edge inside. This is confined to pentamerous flowers only, e.g., sepals of *Ipomoea*, *Vinca* and *Thevetia*.

Vexillary: Same as papilionaceous corolla.

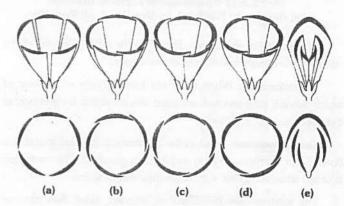

Fig: 2.1-11 Different types of aestivation
(a) Valvate, (b) Twisted, (c) Imbricate,
(d) Quincuncial (e) Vexillary

- (7) Androecium or Stamens: It is the third whorl of a flower consisting of stamens or microsporophylls. Fertile stamens produce pollen grains. Staminodes are the sterile stamens. Petaloid stamens are brightly coloured and appear like petals, e.g., Canna.
- (i) Structure of stamen: A stamen shows a long or short stalk called the filament. The filament ends with a terminal fertile part known as the anther. It encloses microsporangia within which microspores or pollen grains are produced. The filament of the stamen is connected to the anther by means of a "connective". The anther may be monothecous or dithecous. The monothecous anther has only one sac. It is bilocular or bisporangiate, e.g., Hibiscus. The dithecous anther consists of two sacs and is tetralocular or tetrasporangiate as in Datura.

When the face of anther is towards centre of flower it is called introrse e.g., tomato when it is towards the periphery it is called extrorse /e.g., Ranunculus.

(ii) Fixation: The mode of attachment of a filament to anther by connective is called fixation. It is of following types:

Adnate: Filament attached to the total length of the anther on the back. e.g., Michelia (Champa).

Basifixed: Filament is attached to the base of the anther e.g., Datura, Mustard, Radish.

Dorsifixed: Filament is attached to the anther on the dorsal side at middle portion e.g., Passiflora.

Versatile: Filament is attached to the anther at a point so that anther can swing freely in all direction. *e.g.*, Grasses.

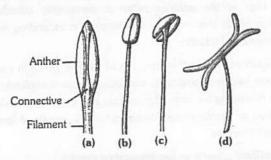

Fig: 2.1-12 Attachment of anther to filament (a) Adnate, (b) Basifixed, (c) Dorsifixed, (d) Versatile

(iii) Length of stamens: Based on the relative lengths of the stamens, the conditions of androecium varies:

Didynamous: When there are four stamens in a flower of which two are long and two are short, the condition is described as didynamous, e.g., Ocimum.

Tetradynamous: Out of the six stamens that are found in a flower, four stamens are long and the two are short. This condition is called tetradynamous, e.g., Raphanus and Brassica.

The stamens are described as inserted when they do not extend beyond the petals or corolla tube (*Dolichos*). When the stamens extend beyond the petals or corolla tube, the stamens are known as exserted (*Acacia*).

(iv) Insertion of stamens: Based on the insertion of stamens, the condition of androecium varies:

Isostemonous: When the stamens form a single whorls and the number of stamen is the same as that of sepals and petals, the flower is isostemonous. (e.g., Solanum) while heterostemonous condition is used for any difference in size., shape or mode of dehiscence.

Diplostemonous: Sometimes there are two whorls of stamens. The first whorl alternating with petals (antisepalous) and the second whorl alternating with sepals (antipetalous). *e.g.*, Cassia.

Obdiplostemonous: In this condition first whorl is antipetalous and the second whorl is antisepalous. *e.g.*, *Dianthus*.

(v) Union of stamens: The union of stamens takes place either among themselves (cohesion) or with other whorls (adhesion). Cohesion of stamen: Usually following types of cohesion among stamens occur. They are:

Adelphous: When the filaments of stamens are united and the anthers remain free. It is of three types:

Monoadelphous: All filaments unite to form a single bundle e.g., Family malvaceae (Hibiscus).

Diadelphous : Filaments unite to form two bundles. e.g., Family papilionaceae (Pisum, Sesbania, Tephrosia). i.e., (q)+1.

Polyadelphous: Filaments unite to form many bundles. e.g., Family rutaceae (Citrus, Melaleuca).

Syngenesious: When the anther of filament are united and the filaments remain free. e.g., *Tridax*, Sunflower etc.

Synandrous: Here all stamens of a flower are united completely to form a single structure. e.g., Family Cucurbitaceae.

Adhesion of stamens: Stamens may unite with other floral organs like sepals, petals or gynoecium. Based on the floral organ involved in the union with stamens, the adhesion may be of the following types:

Epiphyllous: Stamens unite with perianth. e.g., Onion.

Episepalous : Stamens unite with sepals. e.g., Prunus (Peach).

Epipetalous: Stamens unite with petals. e.g., Datura.

Gynandrous: Stamens unite with gynoecium. It is also called gynandrium or gynostegium. e.g., Calotropis.

(8) Gynoecium or Carpels: The gynoecium or pistil is the fourth essential whorl of female reproductive part of the flower and may be made up of one or more carpels (megasporophylls). A carpel has three distinct part, namely ovary, style and stigma.

The lower most swollen fertile part of the carpel is the ovary. It encloses ovules. A sterile pistil is known pistillode. The number of carpels in a gynoecium varies in different flowers.

Monocarpellary: It is a gynoecium with a single carpel, e.g., Bean.

Bicarpellary: It is presence of two carpels in a gynoecium. e.g., Helianthus.

Tricarpellary: It is presence of three carpels in a gynoecium e.g., Cocos.

Tetracarpellary: It is presence of four carpels in a gynoecium. e.g., Cotton.

Pentacarpellary: It is presence of five carpels in a gynoecium. e.g., Hibiscus.

Multicarpellary: It is presence of many carpels in a gynoecium. e.g., Annona.

UNIVERSAL BOOK DEPOT 1960

The ovary encloses one to many chambers called the locules. Based on the number of locules, the ovary may be described as follows:

Unilocular: Ovary with one locule. e.g., Dolichos.

Bilocular: Ovary with two locules. e.g., Solanum.

Trilocular: Ovary with three locules. e.g., Allium.

Tetralocular: Ovary with four locules. e.g., Datura.

Pentalocular: Ovary with five locules. e.g., Hibiscus.

Multilocular: Ovary with many locules. e.g., Abutilon.

Apocarpous : Pistil or gynoecium with separate or free carpels e.g., in Ranunculus

Syncarpous: Condtition of fused carpels.

- (8) Relative position of floral organs on thalamus: Depending upon the form of thalamus and the position of floral whorls with respect to the ovary, the flowers are of the following three types:
- (i) **Hypogyny**: In this case the thalamus is convex and ovary occupies the highest position on it. The outer three whorls, *viz.* sepals, petals and stamens inserted one above the other but below the ovary. Since the ovary lies above the other parts, it is described as superior and the rest of the floral whorls as inferior. A flower having hypogyny is called hypogynous. *e.g.*, China rose, Brinjal, Mustard, etc.
- (ii) **Perigyny**: In some cases, the receptacle or the thalamus forms a swallow or deep cup-shaped structure around the ovary. The pistil is attached at the centre of the concave thalamus. The sepals, petals and stamens are attached at the margins of the thalamus, the flowers are said to be perigynous and ovary is half inferior or half superior. Different type of flowers show different degrees of perigyny. e.g., Rose, Pea, Bean, Prunus, etc.
- (iii) **Epigyny:** In this condition the margin of thalamus grows further upward completely enclosing the ovary and getting fused with it and bear the sepals, petals and stamens above the ovary. The ovary in such cases is said to be inferior and the rest of the floral members superior. *e.g.*, Apple, Sunflower, Cucumber, Guava, etc.

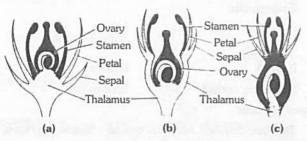

Fig: 2.1-13 Insertion of floral parts on thalamus (a) Hypogynous, (b) Perigynous, (c) Epigynous

(9) Placentation: The ovary contains one or more ovules, which later become seeds. The ovule bearing regions of the carpel is called placenta. The arrangement of placentae and ovules within the ovary is called placentation. The placenta is the cushion-like structure to which the ovules are attached inside the cavity of the placenta, placentation is of the following types:

- (i) Marginal: In this type of placentation, the ovary is simple, unilocular and the ovules are arranged along the margin of the unilocular ovary. The placenta develops along the ventral suture of the ovary. e.g., Pea, Gram, Goldmohur, etc.
- (ii) Axile: It is found in a compound ovary which is two or more chambered, usually as many as the number of carpels e.g., Petunia and Asphodelus. The placentae bearing the ovules develop from the central column or axis which is formed by the fusion of margins of carpels. In certain cases the number of chambers (loculi) increases due to the false septum formation. e.g., Datura, Tomato, etc.
- (iii) Free central: In this free central placentation, the gynoecium is polycarpellary and syncarpous. The ovary in early stages is multilocular, but soon the septa break down leaving it as a unilocular structure. e.g., Dianthus, Slience, Primula, etc.
- (iv) Parietal: In parietal placentation, the ovary is usually one-chambered but in some cases it becomes bilocular due to the formation of false septum called replum, e.g., Brassica compestris (Sarson). The placentae bearing the ovules develop on the inner wall of the ovary at places where the margins of two adjoining carpels meet. The number of placentae corresponds to the number of fused carpels. e.g., Poppy, Mustard, Cactus, etc.
- (v) Basal: In this type of placentation, ovary is bicarpellary, syncarpous and unilocular and a single ovule is borne at the base of ovary. e.g., Marigold, Sunflower, etc.
- (vi) Superficial: The ovary is multicarpellary, syncarpous, and large number of loculi without specific order e.g., Waterlily (Nymphea).

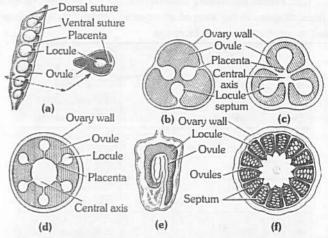

Fig: 2.1-14 Different types of placentations (a) Marginal, (b) Parietal, (c) Axile, (d) Central, (e) Basal, (f) Superficial

- (10) Style: The stalk like structure present above the ovary is called the style. The style may be long (*Datura*) or short (grasses) or absent (*Papaver*). In the family umbelliferae (apiaceae) the base of the style is swollen and forms a structure called stylopodium. There are three types of styles as described below:
- (i) Terminal style: If the style arises from terminal part of the ovary, it is called terminal style, e.g., Datura, Hibiscus and Solanum.
- (ii) Lateral style: If the style arises from one side of the ovary, it is called lateral style, e.g., Mango.

(iii) Gynobasic style: If the style arises from the base of the ovary it is called gynobasic style. It is characteristic feature of family Labiatae., e.g., Ocimum, Salvia.

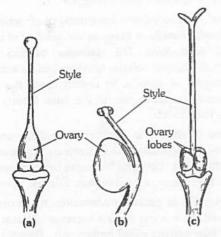

Fig: 2.1-15 Types of styles (a) Terminal, (b) Lateral, (c) Gynobasic style

(11) Stigma: The terminal receptive portion of the style is called the stigma. It receives pollen grains during pollination. Usually the lobes of the stigma corresponds to the number of carpels. Accordingly the stigma may be unifid, bifid, trifid, tetrafid, pentafid or multifid.

Capitate: Round stigma. e.g., Hibiscus.
Forked: Divided stigma. e.g., Tridax.
Feathery: Brush like stigma. e.g., Grasses.

(12) Floral formula: It represents the informations given in a floral diagram in the form of an equation. Following symbols are used in constructing a floral formula.

Br.	Bracteate	C	Corolla-free (polypetalous)
Brl.	Bracteolate	(C)	Corolla-united (gamopetalous)
Ebr.	Ebracteate	Cx	Corolla-cruciform
Ebrl.	Ebracteolate	P	Perianth
ď	Male	A	Androecium-free (polyandrous)
Q	Female	(A)	Androecium-united (synandrous)
₽*	Bisexual	PA	Epiphyllous
⊕	Actinomorphic	C A	Epipetalous
† or %	Zygomorphic	G	Gynoecium-free (apocarpous)
Ер	Epicalyx	(G)	Gynoecium-united (syncarpous)
K	Calyx-free (polysepalous)	G	Superior ovary
(K)	Calyx-united (gamosepalous)	Ğ	Inferior ovary
N	Neuter	G A	Gynostegium

(12) Floral diagram: Following signs are used in constructing a floral diagram.

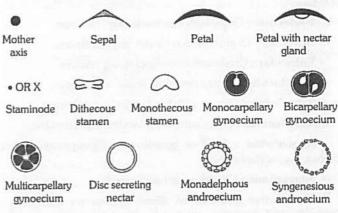

Fig: 2.1-16 Signs used in preparation of floral diagram

Fruit

Formation of fruit: Fruit is defined as fertilized ovary. The ovary develops into fruit. The ovary wall at maturity forms the wall of the fruit, which is known as pericarp. Sometimes, other parts of flower such as tepals, (e.g., Morus), bracts (e.g., Ananas) or thalamus (e.g., Pyrus) are also involved in the formation of fruit and such fruits are called false fruits or pseudocarps.

The fate of various parts of the ovary during the formation of fruits is summarized below:

Ovary	-	Fruits
Ovary wall	-	Pericarp
Ovule	-	Seed
Funiculus	-	Stalk of the seed
Hilum	-	Hilum
Nucellus	-	Perisperm (when present)
Micropyle	_	Micropyle
Outer integument	_	Testa
Inner integument	_	Testa Tegmen Seed coat
Embryo sac		
Synergids	_]
Antipodals	- 1	Degenerate
Egg cell	_	Embryo
Secondary nucleus	-	Endosperm

Types of fruits

They are classified into three groups: Simple, aggregate and multiple or compound fruit.

Simple fruits: They are formed from mono-or polycarpellary but syncarpous ovary. They may be dry or fleshy.

- (1) Simple dry fruits have thin, hard and dry, pericarp.
 They are of three kinds:
 - (i) Dehiscent or Capsular
 - (ii) Achenial or Indehiscent
 - (iii) Schizocarpic

UNIVERSAL BOOK DEPOT 1960

(i) Dehiscent fruit: These fruits are dry, many seeded and split open at maturity. They are of following types:

Legume or Pod : It is characteristic of the family leguminosae; developed from monocarpellary unilocular superior ovary with marginal placentation. It can open or dehisces by both ventral and dorsal sutures. *e.g.*, in *Cicer arietinum* (Gram); *Pisum sativum* (Pea) and *Phaseolus mungo* (Black gram).

Follicle: It is very much resembles the legume but on ripening it opens generally along the ventral suture. *e.g.*, *Calotropis*, *Larkspur*, etc.

Siliqua: The fruit is developed from bicarpellary, syncarpous and superior ovary which bears ovules on two parietal placenta. The ovary is unilocular but later becomes bilocular due to the development of a false partition wall called *replum*. It dehisces from the base towards the apex by both the sutures *e.g.*, In *Brassica* (Mustard) and is characteristic of the family Cruciferae.

Silicula: It is flattened and short in length from siliqua type, found in *Iberis* (Candytuft) and *Capsella bursa* (Shepherd's purse).

Capsule: It is mono or polycarpellary, dry dehiscent, many seeded fruit which developes from a superior or inferior ovary. It dehisces in almost all the ways *i.e.*, longitudinal and transverse, along both the sutures. Majority of capsules show longitudinal-dehiscence which again are of different types:

Loculicidal: Lines of dehiscence appear along the dorsal sutures, e.g., Gossypium herbacium (Cotton) and Abelmoschus esculentus (Lady's finger).

Septicidal: Lines of dehiscence appear along the ventral sutures or septations of the ovaries e.g., in Viola (Pansy), Linseed (Linum).

Septifragal : Lines of dehiscence along irregular lines, but the seeds remain attached to the placenta, as in *Datura stramonium* (Thorn apple).

(ii) Achenial or Indehiscent fruits: These fruits do not burst at maturity but the seeds are liberated only by the decaying of the pericarp. These are of following types:

Achene: It is small, dry one seeded fruit which develops from a superior or inferior monocarpellary ovary. In this type, the pericarp is tough but thin and free from the seed coat, e.g., in Mirabilis (four o'clock plant) and Clematis. Some times achenes occur in a group from apocarpus ovary where carpels are many e.g., Nelumbium (Lotus).

Caryopsis: It is very small, dry and one seeded fruit which develops from a superior monocarpellary ovary. Here the pericarp is closely fused with seed coat. It is the characteristic of family graminae, e.g., Oryza sativa (Paddy), Triticum aestivum (Wheat) and Zea mays (Maize).

Cypsela: It is dry, one seeded fruit which develops from an inferior, bicarpellary ovary. Here the pericarp is free from seed coat but the thalamus is fused with pericarp. The fruit is provided with a crown of hairs at the top called pappus e.g., in Helianthus annuus (Sun flower), Tridax, Cosmos, Sonchus, etc.

Nut or Glans: It is dry, one seeded fruit which develops from a superior, bi or polycarpellary ovary having a hard pericarp, free from seed coat e.g., in Areca catechu (Betalnut), Anacardium occidentale (Cashewnut) and Trapa natans (Water chestnut). Here the thalamus and sometimes the cotyledons of true fruit are also edible.

Samara: It is dry, one or two seeded fruit, develops from a single mono-or bicarpellary ovary. The pericarp is free from testa and produces a wing like outgrowth which helps in the dispersal of seeds e.g., in *Hiptage* and *Elm*.

(iii) Schizocarpic or Splitting fruits: These resemble both (achenial) indehiscent fruits as well as capsular fruits having many seeds. However, they break into one seeded segments known as mericarps. By splitting usually the mericarps are indehiscent but in Ricinus (Castor) they are dehiscent. The important schizocarpic fruits are:

Lomentum: It is a dry, many seeded fruits which develops from a monocarpellary, superior, unilocular ovary with marginal placentation.

The fruit arises just like a legume but when ripened it becomes partitioned between seeds into single seeded mericarps e.g., Acacia arabica (gum tree), Mimosa (touch me not) and Dalbergia sisoo (Indian red wood tree).

Cremocarp: It is a dry fruit, develops from bicarpellary, syncarpous, bilocular ovary. The fruit when mature breaks into single seeded mericarps which remain attached to the top of the central axis called carpophore, e.g., Daucus carota (Carrot); Foeniculum vulgare (fennel).

Regma: It develops from tri-or penta-carpellary superior syncarpous ovary. The locules are many as the carpels known as *Cocci* (sing. Coccus), attached to carpophore and separate by splitting e.g., Euphorbia, Geranium and Ricinus.

Carcerulus: It is a dry fruit, develops from bi or polycarpellary syncarpous, multilocular superior ovary with axile placentation. Many single seeded, mericarps are formed by splitting and formation of false septa. e.g., Ocimum sanctum (Sacred basil), Althaea rosea.

(2) Simple fleshy fruit: The fruits are simple, but the pericarp is fleshy and edible. It is differentiated into three layers epicarp, mesocarp and endocarp. Fleshy fruits are of following types:

Drupe: It is a fleshy fruit formed from monoor poly carpellary superior ovary, where one or more ovules may develop into seeds. Here the epicarp is thin and leathery. The mesocarp is thick, fleshy, juicy and edible in *Mangifera* (Mango) and fibrous in *Cocos* (Coconut).

The endocarp is hard and stony in both the cases. In Cocos, pericarp is not edible. The portion inner to endocarp is the liquid endosperm which is edible.

Berry: It is usually many seeded fleshy fruit develops from polycarpellary, syncarpous, superior ovary. Rarely it is single seeded as in *Borassus* (Palm).

Here the epicarp remains as the skin of the fruit. The mesocarp and endocarp are fused together to form the pulp of the fruit. e.g., Brinjal, Tomato, Banana, etc.

Pepo: It is a special type of berry. Here the epicarp and thalamus form the outer ring of the fruit. The mesocarp, endocarp and placentae are fused to form pulp which is edible; seeds are many. It is characteristics fruit of family cucurbitaceae. Common examples are Cucurbita maxima (Sweet gourd); Cucumis sativa (Cucurbit).

Pome: The fruit develops from inferior, pentacarpel ovary. The fruit is covered by the fleshy thalamus, which is fused with the pericarp and edible. The outer part again encloses the inner stiff and membranous portion enclosing the seeds; common example is *Pyrus indica* (Apple).

Table: 2.1-1: Edible Parts of Some Fruits

Wheat	Endosperm and embryo
Maize	Endosperm and embryo
Litchi	Fleshy aril
Orange	Unicellular juicy hairs from endocarp
Lemon	Unicellular juicy hairs from endocarp
Apple	Fleshy thalamus
Pear	Fleshy thalamus
Strawberry	Fleshy thalamus
Banana	Mesocarp and endocarp
Cucumber	Mesocarp and endocarp
Muskmelon	Mesocarp and endocarp
Walnut	Cotyledons
Groundnut	Cotyledons and embryo lobe
Cashewnut	Cotyledons and fleshy pedicel
Pea	Cotyledons and embryo
Pomegranate	Juicy testa
Indian plum	Epicarp and mesocarp
Guava	Pericarp and placenta
Grape	Pericarp and placenta
Jack fruit	Bracts, perianth and seeds
Pineapple	External rachis, bracts, perianth and seed
Mulberry	Perianth
Fig	Rachis or fleshy receptacle
Coconut	Endosperm
Lotus	Thalamus and seeds
Custard apple	Mesocarp

Hesperidium: It is another type of berry; it develops from a polycarpellary, syncarpous, superior ovary with many seeds. Here the outer skin is thick and leathery that represents the epicarp, which contains oil glands. The fibrous portion fused with epicarp is the mesocarp. The endocarp consists of many chambers with juicy glands. Common examples are *Citrus medica* (Lemon) and *Citrus sinensis* (Sweet orange).

Balausta: This is many chambered, many seeded fruit developing from a multicarpellary, syncarpous but inferior ovary. The pericarp of balausta is leathery or tough. The carpels are arranged in two rows. Calyx is persistent. The seeds have succulent seed coat (testa) which form the edible part; e.g., Punica granatum (Pomegranate).

Aggregate fruits: The aggregate fruits are formed from polycarpellary, apocarpous ovary. Each ripened is called *fruitlet* or etaerio e.g., the *lotus*, rose fruit and strawberry are a collection of achenes; raspberry, a collection of drupes and custard apple is a collection of berries.

Composite or compound fruits : Multiple fruit develops from entire inflorescence called sorosis or syconus.

Sorosis : Develops from spike or spadix inflorescence e.g., Pineapple, Jackfruit, Mulberry, etc.

Syconus : Develops from hypanthodium inflorescence *e.g.*, *Ficus carica*. (banyan).

Seed

Morphologically, ripened ovule is known as seed. In other words, seed is mature integumented megasporangium.

Development of seed: The fertilized ovule forms seed. The ovule increases greatly in size. The integuments dry up. The outer one becomes hard or leathery and forms the outer seed coat or testa while the inner one, if persist, forms the tegmen.

The nucellus is generally used up during the development of embryo but in some cases it remains outside the endosperm in the form of a thin layer, called *perisperm*. The endosperm may persist or completely digested during embryogenesis.

A scar is usually visible on one side of the outer seed coat. It is known as *hilum* and marks the point of attachment to the stalk. With these changes, the ovule changes into seed and enters a period of dormancy while the ovary ripens into a fruit.

Dicotyledonous seeds

Exalbuminous : Gram, Pea, Bean, Mustard, Mango, Groundnut, etc.

Albuminous: Castor, Poppy, Artabotrys, Custard apple (Ananas) etc.

Monocotyledonous seeds

Exalbuminous : Orchids, Alisma, Najas, Pothos, Amorphophallus, Vallisneria, etc.

Albuminous: Cereals, Millets, Palms, Lilies, etc.

UNIVERSAL BOOK DEPOT 1960

Non-endospermic or Exalbuminous seeds : In exalbuminous seeds endosperm is completely consumed by the developing embryo, and the mature seeds are without endosperm. The food is stored in cotyledons.

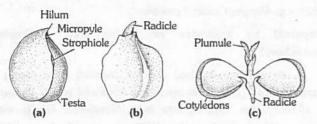

Fig: 2.1-17 Structure of gram seed

Endospermic or Albuminous seed : In albuminous seeds, embryo not consumed all endosperm. So it persists in the mature seed. In these seeds food stored in endosperm. In monocot seed the membranous covering of :

- Radicle is called coleorrhiza.
- Plumule is called coleoptile.

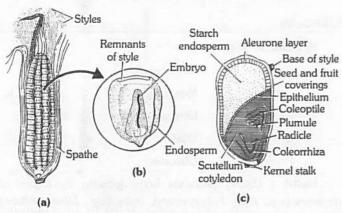

Fig: 2.1-18 Structure of maize grain
(a) Entire seed; (b) Grain in L.S. (c) Grain in T.S.

Germination of seeds: The process by which the dormant embryo of the seed resumes active growth and grows into a new plant is known as germination.

Types of seed germination

Epigeal germination: In this type of germination, the cotyledons come above the surface of the soil into the air and light due to the rapid growth and elongation of the hypocotyl. The cotyledons turn green and finally dry up and fall off and seedling becomes an independent plant. Germination of seeds of Bean, Gourd, Castor, Cotton, etc. is of epigeal nature.

Hypogeal germination: In this type of germination, the cotyledons remain in the soil or just above the surface. In this case epicotyl elongates pushing the plumule upwards. The cotyledons do not turn green and gradually dry up and fall off. Common examples of hypogeal germination are the seeds of Pea, Mango, Groundnut, etc.

Viviparous germination: This is a special type of germination found in mangrove plants. The embryo grows not only out of the seed but also out of the fruit and projects from it in the form of a green seedling displaying root and hypocotyl. Due to its increasing weight the seedlings separate from the parent tree and falls into the mud or water and soon develops lateral roots. Vivipary is seen in *Rhizophora* and *Sonneratia*.

Factors for seed germination

External factors: Water, oxygen, suitable temperature.

Internal factors: Foods and growth regulators, completion of rest period, viability.

Seed dormancy: In several plants seeds germinate as soon as they have undergone maturation and provided proper conditions for germination. *e.g.*, seeds of Bean, Pea, Maize etc. In some plants seeds are incapable of germination because of some inhibitory factors. Such seeds are unable to germinate even under suitable conditions. This is called seed dormancy.

Viability of seeds : Germinating ability of the seed is called its viability. Only viable seeds are able to germinate. As the viability expires, the embryo dies and seed looses its capacity of germination. Viability of seeds varies from species to species.

□ Longest seed viability is reported in *Nelumbo nucifera* (= *Nelumbium speciosum*) or **Indian lotus** (Kamal). Here the viability is reported to be **more than two hundred years.**

Causes of seed dormancy

The seed dormancy may be due to many causes some of which are as follows:

- (1) Impermeability of seed coats to oxygen. (e.g., Xanthium) and water. (e.g., Chenopodium and many leguminous seeds).
- (2) Seed coat is mechanically hard, thus resisting the growth of embryo. e.g., Mustard, Capsella, Amaranthus.
- (3) Presence of rudimentary or immature embryo. e.g., Ginkgo biloba (a gymnosperm).
- (4) Some plants produce such chemical compounds that inhibit the germination of their own seeds. e.g., Tomato, (possesses inhibitor ferulic acid).

Dispersal of fruits and seeds

Dispersal by wind (Anemochory)

The wind is probably the most important agency of seed dispersal in nature. The fruits and seeds show following devices which help in dispersal by wind.

Light weight and minute seeds: Seeds of some plants (e.g., Orchids) are sufficiently light and minute in size to be easily carried away to great distances by air currents.

Winged seeds and fruits: Some seeds (e.g., Oroxylon, Cinchona, Moringa) or fruits (Acer, Hiptage, Terminalia, Dipterocarpus) develop one or more thin membranous wings to ensure their dispersal by wind.

Parachute mechanism: In members of the family Asteraceae (Compositae) e.g., Taraxacum, Sonchus, sepals are modified into tufts of hairs called pappus. The pappus is persistent and hence found attached to even small, single seeded fruits. It acts like a parachute that allows the wind to carry them to great distances. Seeds of many nasty weeds are also dispersed by this method.

Coma: One or more tufts of hairs are attached on seeds constitute coma, e.g., Calotropis, Cotton etc.

Censer mechanism: In Antirrhinum (dog flower), Aristolochia, Papaver (poppy), Argemone mexicana (Prickly poppy), Nigella (love-in-a-mist), etc. the fruit is a capsule. At maturity it ruptures but the seeds do not come out. However, when the capsule is shaken violently by the wind, the seeds are scattered in all directions. In this process all the seeds do not escape together.

Rolling mechanism: In some species, like Amaranthus albus, Chenopodium album, etc., plants dry out after bearing fruits and seeds. Eventually the entire plant breaks off at the base of the stem due to the force of wind and rolls over the ground, shedding the seeds all along the way. Such rolling plants are collectively known as tumble weeds.

Hairs: In cotton, hairs are the outgrowth from the seed coat and occur all along its surface.

Persistent styles: Clematis, Naravelia, Geranium etc. have persistent and feathery styles which help the fruit to be easily carried by wind.

Balloon like appendages: In plants like Cardiospermum and Nicandra fruits develop balloon like appendages which make the fruits light to be easily carried by wind.

Dispersal by water (Hydrochory)

Fruits and seeds, specialized for dispersal by water, generally develop some kind of floating devices and a protective covering which makes them water resistant. e.g., fibrous mesocarp in Coconut, spongy thalamus in Lotus. The seeds of *Polygonum* can beheld over the surface of water and dispersed.

Dispersal by animals (Zoochory)

Fruit and seeds dispersed by animals can be divided into following three categories on the basis of their adaptive features

Hooked fruits and seeds: The surface of many fruits is covered with hooks (e.g., Xanthium, Urena), barbs (e.g., Andropogon), spines (e.g., Tribulus), bristles (e.g., Pupalia), or stiff hairs (e.g., Aristida), by means of which they adhere to the body of animals or clothes of human beings and they are carried unwarily from one place to another.

Sticky fruits and seeds: Some fruits like those of Boerhaavia, Cleome, and Plumbago have sticky glands by which they adhere to the fur of grazing animals and are thus dispersed. Seeds of Viscum (mistletoe), Loranthus, etc. have a viscid layer which adhere to the beak of the bird which eat them. Sticky seeds of Rafflesia are dispersed by elephants.

Edible fruits: (i) The seeds are very small and capable of passing unharmed through digestive tract of animals (e.g., Mulberry, Peepal, Guava, Banyan, Tomato). (ii) The seeds are large so that they are thrown away, e.g., Apricot, Mango. (iii) Sticky so that stick to the beaks of birds. The seeds are thrown away by rubbing of beaks, e.g., Viscum, Cordia, Loranthus.

Dispersal by explosive or Spring like mechanism (Autochory)

A less common method of seed dispersal is by means of explosive fruits. Such fruits open with force and scatter the seeds in all directions. e.g., Balsam fruit (Impatiens), Oxalis, night jasmine (Nyctanthus), castor (Ricinus), camel's foot climber (Bauhinia vahlii), Pea etc. Another example of autochory is the seeds of Ecballium (squirting cucumber). In squiring cucumber the fleshy and spiny fruit wall encloses a mucilaginous mass having seeds. The tip of the stalk functions as a plug. Diturbance breaks the fruit from the stalk. The mucilage containing the seeds is thrown out with a great force.

Taxonomy of Angiospermic plants

Liliaceae

Systematic position

Division : Angiospermae

Class : Monocotyledonae

Series : Coronarieae

Order : Liliales
Family : Liliaceae

Habit: Usually perennial herbs growing by means of rhizomes (e.g., Aloe, Polygonatum), bulbs (e.g., Lilium, Allium) and corms (e.g., Colchicum). Some herbs are annual (e.g., Asphodelus). Shrubs occur in Aloe, Agave, Yucca (Dagger plants, Adam's Needle), Dracaena (Dragon plant), and Ruscus (Butcher's Broom). They mostly grow in arid areas and are hence xerophytic (e.g., Aloe, Yucca). Xanthorrhoea of Australia is tree-like. Climbers are seen in Smilax, Gloriosa and species of Asparagus.

Root: Adventitious, fibrous or tuberous (e.g., Asparagus).

Stem: Erect or climbing as *Smilax*, branched or unbranched, herbaceous, phylloclade as *Ruscus*. Cladode as *Asparagus*, Bulb as *Allium cepa*.

Leaves: Radical or cauline and ramal show various types of phyllotaxy (alternate, opposite or whorled), exstipulate, stipulate in Smilax where the stipules are prolonged into tendrils, sessile or petiolate with sheathing leaf bases, venation parallel but reticulate in Smilax, leaves may be scaly, leathery, fleshy or modified into spines (e.g., Asparagus), leaf apex is tendrillar in Gloriosa. The leaves of Phormium tenax (New Zealand Hemp) are 3 metres long and 10 cm broad.

UNIVERSAL BOOK DEPOT 1960

Inflorescence : Recemose, sometimes solitary (e.g., Tulipa, Gloriosa) or umbellate condensed cymes (umbel cyme), e.g., Onion. In several cases the inflorescence possesses a leafless peduncle called scape.

Flower: Bracteate or ebracteate, pedicellate, regular, trimerous actinomorphic, zygomorphic in a few cases (e.g., Gilliesia), complete or incomplete, perfect, unisexual in Smilax and Ruscus, hypogynous, generally pentacyclic, trimerous (rarely bimerous or tetramerous). Accessory floral organs undifferentiated and collectively called perianth.

Perianth: Tepals 6 (coloured), in two whorls of 3 each, free or fused, sepaloid or petaloid, scarious or membranous, aestivation valvate or imbricate, distinguished into calyx and corolla in *Trillium*.

Androecium: Stamens 6 (3 in *Ruscus*, 9–12 in *Tofieldia*), free (polyandrous) or monadelphous (e.g., *Ruscus*), arranged in two whorls, antiphyllous (antitepalous), may be epiphyllous (or epitepalous), anthers fixed variously (basifixed, dorsifixed, versatile), dehiscence longitudinal or by pores.

Gynoecium : Tricarpellary, syncarpous, ovary superior, trilocular with 2-many ovules in each locules, placentation axile, rarely parietal, styles united or separate, stigma free or fused, trilobed.

Fruit: A capsule (e.g., Asphodelus, Gloriosa) or berry (e.g., Asparagus).

Seed: Endospermic and monocotyledonous.

Floral formula : $\oplus \not\subset P_{(3+3)} A_{3+3} G_{(\underline{3})}$

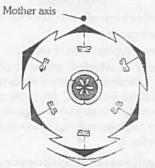

Fig: 2.1-19 Floral diagram of liliaceae (Allium cepa)

Economic importance of the family

(1) Sources of medicines

(i) Colchicum luteum and C. autumnale (Hirantutiya): An alkaloid 'Colchicine' is obtained from seeds and corms, which is used in the cure of rheumatism and liver disorders.

It is also drug of choice in acute gout.

Beside **Colchicine** is used for inducing polyploidy in plant breeds by arresting or breaking spindle formation.

(ii) Aloe vera (Aloe or Ghee Kawar): Used in many laxative preparations and also used in curing piles and fissures.

(iii) Urginea indica and U. maritima (Indian squill): Bulbs stimulate heart and are also used in rhematism and skin diseases.

Raticide or Red-squill is prepared from bulbs of red variety, which is an important raticide (rat killer) for more than 20 years.

- (iv) Smilax macrophylla and S.glabra (Sarasparilla): Roots provide a drug called 'Sarasparilla' which is cure of venereal and skin diseases.
- (v) Gloriosa superba (Malabar glory lily): Tubers are used in promotion of labour pains and juice of leaves is used for killing lice.

(2) Sources of food

- (i) Allium cepa (Onion or Piaz)
- (ii) Allium sativum (Garlic or Lahsun)
- (iii) Asparagus officinalis and A. racemosus (Satawar)

(3) Source of fibres

- (i) Sansevieria roxburghiana (Bowstring hemp): Leaves provide a strong fibre, which is used for making bowstrings and fishing nets.
- (ii) Yucca filamentosa (Dagger plant): Leaves provide fibres used for cordage.

(4) Ornamentals

- (i) Tulipa sps. (Tulip): Beautiful flowers, etc.
- (ii) Lilium bulbiferum (Lily): For beautiful flowers.
- (iii) Yucca gloriosa: White flowers giving perfume during night.
 - (iv) Gloriosa superba.
 - (v) Asparagus plumosus (Asparagus fern).

Cruciferae or Brassicaceae (Mustard family)

Systematic position

Division : Angiospermae
Class : Dicotyledonae
Subclass : Polypetalae
Series : Thalamiflorae

Order : Parietales

Family : Cruciferae (Brassicaceae)

Habit: Annual, biennial or perennial herbs. Farsetia jacquemontii is an undershrub. The plants possess pungent juice having sulphur-containing glucosides.

Root: Tap root alongwith hypocotyl is swollen in Radish (Raphanus sativus) and Turnip (Brassica rapa).

Stem: Erect, cylindrical, hairy or glabrous, herbaceous or rarely woody. It is reduced in the vegetative phase in Radish and Turnip. The stem is swollen in Kohlrabi (Knol-Kohl = Ganthgobi, Brassica oleracea var. gongylodes). Axillary buds enlarged in Brussel's Sprouts (= Button gobhi) or Brassica oleracea var. gemmifera. Brassica oleracea var. capitata (Cabbage) has the largest terminal bud.

Leaves: Radical, cauline and ramal, alternate or subopposite but forming rosettes when radical, exstipulate with sheathing leaf base, sessile simple or rarely compound (e.g., Nasturium officinale), hairy. Bulbils occur in the leaf axils of Dentaria bulbifera and on the leaves of Cardamine pratensis.

Inflorescence: Flowers are usually arranged in corymbose racemes. Occasionally they are in corymbs (candituft).

Flower: Ebracteate or rarely bracteate (e.g., Rorippa montana), pedicellate, complete, perfect, regular, actinomorphic, rarely zygomorphic (e.g., Iberis, Teesdalia), tetramerous or bimerous, hypogynous (perigynous in Lepidium), cyclic, cruciform.

Calyx: Sepals 4, polysepalous, aestivation imbricate, generally arranged in two whorls, outer of antero-posterior sepals and inner of lateral sepals, lateral sepals generally saccate or pouched at the base, green or petaloid, inferior.

Corolla: Petals 4, polypetalous, arranged in one whorl and alternate with sepals, often with long claws and spread out in the form of a Greek cross. This arrangement of petals which is characteristic of the family is known as the cruciform arrangement and corolla is described as cruciform corolla, valvate aestivation. Petals reduced or absent in Lepidium and Rorippa.

Androecium: Stamens 6, (four in Cardamine hirsuta, two in Coronopus didymus, 16 in Megacarpaea), free (polyandrous), tetradynamous, arranged in two whorls, outer of two short lateral stamens while the inner whorl is made up of 4 long stamens arranged in two median pairs, anthers basifixed or dorsifixed, dehiscence longitudinal. Green nectaries are often associated with the bases of stamens.

Gynoecium: Bicarpellary (tricarpellary in species of Lepidium, tetracarpellary in Tetrapoma and Tropidocarpum), syncarpous, carpels placed transversely, ovary superior, placentation parietal, ovary bilocular due to the presence of a false septum called replum, style short, stigma capitate, simple or lobed.

Fruit: Siliqua or silicula, lomentaceous siliqua occurs in radish.

Seed: Non-endospermic, often oily.

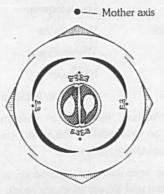

Fig: 2.1-20 Floral diagram of cruciferae (Brassica campestris)

Economic importance of family

(1) Medicines and spices

- (i) Rorippa montana: It is stimulant and also a good appetizer.
- (ii) Cherianthus cheiri : Fever and bronchitis are cured by the seeds of this plant.

- (iii) Lepidium sativum: Liver troubles, asthama and piles are cured by tender shoots.
 - (iv) Iberis amara: In gout and rheumatism.
 - (v) Lobularia: Used in gonorrhoea.
- (vi) B. alba, B. nigra and B. juncea (rye): Seeds are used as spices.

(2) Vegetables (Food)

- (i) Brassica rapa (Turnip or Shalagm)
- (ii) B. oleracea var. caulorapa (gongylodes) (Knol Khol or Ganth gobhi)
 - (iii) B. oleracea var, capitata (Cabbage or Band Gobhi)
 - (iv) Brassica campestris var. sarson (Pili Sarson)
 - (v) B. oleracea var. botrytis (Cauliflower or Phool Gobhi)
 - (3) Oils
 - (i) Eruca sativa (Taramira): Taramira oil is obtained from seeds.
 - (ii) Brassica juncea (Indian mustard or Rye): Seeds produce oil.
- (iii) Brassica napus or B. campestris var. toria Seeds are source of 'Indian rape oil' or Tel toria.
- (iv) Brassica campestris : Seeds are source of **Colza** (Sarson Ka Tel).

(4) Ornamentals

- (i) Iberis amara (Candytuff or Chandini): Winter herb grown for its white, beautiful flowers.
 - (ii) Cherianthus cheiri (Wall flower).

Leguminosae or Fabaceae

Systematic position

Division : Angiospermae
Class : Dicotyledonae
Subclass : Polypetalae
Series : Calyciflorae
Order : Rosales
Family : Leguminosae

Habit: Annual or biennial, herb, shrub or tree.

Root: Tap root system.

Stem: Erect or creeping, solid or weak.

Leaf: Alternate or whorled, stipulate, petiolate, simple or usually compound, reticulate venation. Leaves or leaflets modified into tendrils, two lateral leaflets of telegraph plant (*Desmodium motorium* or *D. gyrans*) show autonomous movements.

On the basis of inflorescence and flower characters, this family is divided into 3 subfamilies :

Subfamily - Papilionatae (Papilionaceae)

Inflorescence: Racemose or solitary axillary.

Flower: Bracteate or ebracteate rarely bracteolate (e.g., Arachis), pedicellate, complete, irregular, zygomorphic, perigynous occasionally, hypogynous, pentamerous.

Calyx: Sepals 5, gamosepalous, usually campanulate, lobes unequal, rarely tubular (e.g., Cyamopsis), odd sepal anterior, may be persistent, inferior.

Corolla: Petals 5, polypetalous, papilionaceous, descending imbricate aestivation, one posterior long standard, two lateral short wings, two anterior petals jointed to each other forming keel.

Androecium: Stamens 10, usually diadelphous (9+1 in Lathyrus, 5+5 in Aeschynomene) or monadelphous (9 in Dalbergia, 10 in Arachis and Erythrina indica), rarely free (e.g., Sophora), nectar gland often present on the inner bases of filaments, anther lobes bilocular, dorsifixed, introrse.

UNIVERSAL BOOK DEPOT 1960

Gynoecium : Monocarpellary, ovary superior, unilocular with marginal placentation ovary covered by staminal tube, style bent, stigma simple or capitate.

Fruit: Legume or lomentum.

Floral formula : Br % $Q^T K_{(5)} C_{1+2+(2)} A_{1+(9)} G_1$

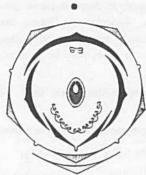

Fig: 2.1-21 Floral diagram of subfamily Papilionatae (Pisum sativum)

Subfamily - Caesalpinoideae (Caesalpiniaceae)

Inflorescence: Raceme, umbel or a solitary flower.

Flower: Bracteate or ebracteate, pedicellate, hermaphrodite, complete, zygomorphic, hypogynous.

Calyx: Sepals 5, polysepalous, imbricate aestivation.

Corolla : Petals 5, polypetalous, ascending imbricate aestivation.

Androecium: 10 stamens, or staminodes are found as in *Cassia*, free filaments of unequal size, anther lobes bilocular, introrse, versatile.

Gynoecium : Monocarpellary, unilocular, ovary superior, marginal placentation, stigma capitate.

Fruit: Legume.

Floral formula: $\% \not\subset K_5 C_5 A_{1+2+2+3(staminodes)}$ or

 $_{7+3(staminodes)} \underline{G_1}$

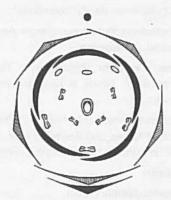

Fig: 2.1-22 Floral diagram of subfamily Caesalpinoidae (Cassia fistula)

Subfamily - Mimosoideae (Mimosaceae)

Inflorescence : Head or capitulum or spike, flowers arranged in acropetal succession.

Flower: Bracteate or ebracteate, sessile, hermaphrodite, complete actinomorphic, hypogynous, pentamerous.

Calyx: 5 sepals (4 in *Mimosa*) gamosepalous, connate at the base, valvate aestivation, rarely imbricate (e.g., *Parkia*).

Corolla : 5 petals (4 in *Mimosa*) gamopetalous or polypetalous, membranous, valvate aestivation.

Androecium: In most of the members, stamens are indefinite and polyandrous. However, there are only 4 stamens in *Mimosa pudica* and 10 each in *Prosopis* and *Dichrostachys*. Filaments are long, usually connate at the base, sometimes they are coloured and gland dotted. Anthers are dithecous and introrse.

Gynoecium : Monocarpellary, unilocular, ovary superior, style long, cylindrical, stigma single and capitate, marginal placentation.

Fruit: Lomentum.

Floral formula: Br or Ebr $\oplus \not \subset K_{(4)} C_4 A_4 G_1$

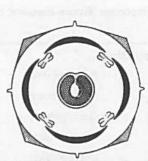

Fig: 2.1-23 Floral diagram of subfamily Mimosoidae (Mimosa pudica)

Economic importance of family

(1) Source of pulses (food)

Pulses we eat, are obtained from seeds of the members of this family, which are **rich source of proteins**.

- (i) Pisum sativum (Garden pea or pea).
- (ii) Cicer arietinum (Chick pea or Gram or Bengal gram).
- (iii) Cajanus cajan (Pigeon pea or Red gram or Arhar).
- (iv) Vigna radiata (Green gram or Moong).
- (v) V. mungo (Black gram or Urd).
- (vi) V. sinensis (Cow pea or Lobia).
- (vii) Lens culinaris Syn. L. esculenta (Lentil or Masoor).
- (viii) Phoseolus vulgaris (French bean): Vegetable.
- (ix) P. aconitifolius (Dal moth).
- (x) Trigonella foenum-graecum (Fenugreek or Methi).

Leaves are used as source of vegetable. Seeds are used as spice.

- (xi) Glycine max (Soybean): Seeds are very rich in proteins (42%). Soya milk is also prepared from it.
 - (xii) Arachis hypogea (Groundnut or Peanut or Moongphali).
 - (xiii) Dolichos lablab (Sem): Vegetable.
 - (xiv) Lathyrus sativus (Grass pea or Khesari dal)

- (2) Timber: Dalbergia sissoo (Shisham or Indian red wood) and D. latifolia (Kali shisham or Indian rose wood or Inidian balck wood).
- (3) Ornamentals: Butea monosperma (Palas or Dhak): Deep red flowers and thus it is also called 'flame of the forest'
 - (4) Other miscellaneous plants
- (i) Indigofera tinctoria (Indigo or Neel): Indigo dye used in dyeing and printing cotton, is obtained from this plant.
- (ii) Abrus precatorius (Ratti or Crab's eye): Seed of this plant are used by jewellers for weighing purpose. Each seed is having constant weight of 1.75 grains.
 - ☐ Leaf juice used for cure of leucoderma (skin disease).
- (iii) Crotolaria juncea (Sun hemp): Fibres from phloem and pericycle of stem (bast fibres) are obtained used for making ropes, mats etc.
 - ☐ It is also important 'Green manure' crop.

Solanaceae

Systematic position

Division : Angiospermae
Class : Dicotyledonae
Subclass : Gamopetalae
Series : Bicarpellatae
Order : Polimoniales
Family : Solanaceae

Habit: Mostly herbs (Petunia, Solanum nigrum, Nicotiana, Withania), shrubs, a few trees (Solanum grandiflorum or potato tree) or climbers (Solanum jasminoides or potato vine, Solanum dulcamara).

Root: Branched tap root system.

Stem: Usually the stem is erect, solid, cylindrical and branched. Occasionally, it is spinous (*Solanum xanthocarpum*, *Datura stramonium*, *Lycium*). In potato (*Solanum tuberosum*) underground stem is modified into tubers.

Leaves: Cauline, ramal, exstipulate petiolate or sessile, alternate, sometimes opposite, simple, entire, pinnatisect in tomato (*Lycopersicum esculentum*). Venation unicostate reticulate, variegated in *Solanum jasminoides*.

Inflorescence: Axillary or extra axillary cyme. Solitary axillary in *Physalis* and *Pentunia*. Sub-sessile umbellate cyme in *Withania somnifera*, solitary in *Datura*.

Flower: Bracteate or ebracteate, pedicillate, complete, actinomorphic, rarely zygomorphic (e.g., Salpiglosis, schizanthus), bisexual, rarely unisexual (e.g., Withania coagulans) pentamerous, hypogynous.

Calyx: Sepals 5, gamosepalous, tubular or campanulate, persistent, accrecent (enlarging in fruit, e.g., Physalis, Withania), Valvate or imbricate, green or coloured, hairy.

Corolla: Petals 5, gamopetalous, tubular or infundibuliform, valvate, twisted in *Datura*, bilabiate in *Schizanthus*, scale or hair like outgrowth may arise from the throat of the corolla tube, coloured.

Androecium: Stamens 5, rarely 4 (e.g., Salpiglossis) or 2 (e.g., Schizanthus), epipetalous, polyandrous alternate to petals, filament inserted deep in the corolla tube, anthers dithecous, usually basifixed or dorsifixed, introrse.

Gynoecium: Bicarpellary, syncarpous, ovary superior, carpels placed obliquely in diagonal plane, generally bilocular (2-4 locular in tomato, 4-locular in *Datura* due to false septa), placentation axile, ovules many in each locules, placentae swollen, a nectariferous disc or lobes may be present, stigma capitate or bifid.

Fruit: A many seeded berry (e.g., Tomato) or capsule (e.g., Datura).

Seed: Endospermic with straight or curved embryo.

Floral formula : $\oplus \not\subset K_{(5)} \stackrel{\frown}{C}_{(5)} \stackrel{\frown}{A}_5 G_{(2)}$

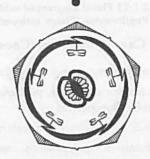

Fig: 2.1-24 Floral formula of Solanaceae (Solanum nigrum)

Economic importance of the family.

(1) Medicinal plants

(i) Datura stramonium (Datura or Jimsonweed): Drug 'Stramonium' is obtained from dried leaves and flowering tops, which is used in treatment of asthama. Atropine, hyoscyamine and hyocine alkaloids are also obtained from this.

Seeds of this plants are deadly poisonous.

- (ii) Atropa belladona (Belladona or sag Angoor) : **Roots** are source of an alkaloid 'Atropine'
- (iii) Withania somnifera (Asgandha): Drug **Asgandh** is obtained from its roots, which is used in rheumatism, female troubles and cough.
- (iv) Hyoscyamus niger (Henbane): Drug **Henbane** is obtained from dried leaves and flowering tops, which is used for sedation and also in asthama and whooping cough.

(2) Food plants

- (i) C. frutescents (Shimla Mirch)
- (ii) Capsicum annum (Chillies or Red pepper)
- (iii) Lycopersicon esculentum (Tomato or Love apple)
- (iv) Solanum melongena (Egg plant or Brinjal)
- (v) Solanum tuberosum (Potato or Alu)
- (3) Source of tobacco: Nicotiana tabacum (tobacco): It is source of alkaloid – 'Nicotin' and highest nicotine content is present in Nicotiana rustica.

UNIVERSAL BOOK DEPOT 1960

(4) Ornamentals

- (i) Petunia alba, P. hybrida: Flowers of different colours like white, pink etc.
 - (ii) Cestrum nocturnum (Night Jasmine or Rat Ki Rani).
 - (iii) C.diurnum (Day Jasmine or Din Ka Raja)
 - (iv) Brunfelsia hopeana (Yesterday, today, tomorrow plant).
 - (v) Schizanthus (Butterfly flower).
 - (5) Others
 - (i) Solanum nigrum (Night shade plant or Makoa).

Malvales

Family

Malvaceae

Habit: Plants are annual herbs (e.g., Malva, Sida, Malvastrum, Urena) shrubs (e.g., Hibiscus rosa-sinensis, H. mutabilis) or rarely trees (e.g., Kydia, Bombax).

Root: Branched tap root system.

Stem: Stem is erect, aerial, herbaceous or woody, usually solid, cylindrical and branched. Herbaceous portion of the stem is covered with stellate and scaly hairs; the woody part is fibrous. Plants usually have some mucilaginous substance.

Leaves : Leaves are alternate and stipulate (stipules 2, free lateral and often Caducous). They are simple and petiolate, lamina is sometimes palmately lobed (e.g., Gossypium) or digitate (e.g., Bombax). Venation is multicostate reticulate.

Inflorescence: Usually the flowers are solitary axillary or terminal. Occasionally, they are in panicle raceme (e.g., Kydia).

Flowers : Flowers are bracteate or ebracteate, actinomorphic, bisexual (unisexual in *Kydia*), pentamerous and hypogynous. The number of bracteoles varies from 3 to many, they form a whorl of epicalyx below the calyx. Sometimes the epicalyx is absent (e.g., *Sida* and *Abutilon*).

Calyx: Sepals 5, gamosepalous (connate at the base but free at the tip) and show valvate aestivation. Usually epicalyx present.

Corolla : Petals 5, polypetalous (slightly fused at the base), usually adnate at the base to the staminal tube. They show twisted or imbricate aestivation.

Androecium: It has indefinite stamens. They are monoadelphous. Filaments of the stamens are united to form a long staminal tube or staminal column which encloses the style. Basal part of the staminal tube is fused with the petals; thus stamens are epipetalous. Anthers are monothecous, reniform, transversely attached to the filament and extrorse. In Bombax stamens are polyadelphaous.

Gynoecium: It is 2 to many carpellary. It is bicarpellary in *Plagianthus*, tricarpellary in *Kydia*, pentacarpellary in *Hibiscus* and *Sida*, ten carpellary in *Althaea rosea* and 15 – 20 carpellary in *Abutilon indicum*. All the carpels are fused (syncarpous) to form a single ovary. Ovary is superior, multilocular with one or more ovules in each chamber. The placentation is axile.

Style is usually long and enclosed in the staminal tube. Stigmas are as many as the number of carpels or double the number of carpels.

Fruit: Fruit is a loculicidal capsule (e.g., Gossypium, Hibiscus), schizocarpic capsule (e.g., Abutilon, Sida) or a berry (e.g., Malvastrum).

Seed : Seeds are albuminous. In *Gossypium* the seeds are pubescent, i.e., covered with hairs.

Floral formula: $\operatorname{Br} \oplus \mathcal{Q}^{\mathsf{E}}\operatorname{Epi}_{3-\infty} K_{(5)} C_5 \stackrel{\wedge}{A}_{(\alpha)} \underline{G}_{(2-\alpha)}$

Fig: 2.1-25 Floral diagram of Malvaceae (Hibiscus rosa sinensis)

Economic importance

(1) Fibre yielding plants

- (i) Abutilon theophrasti (Indian Mallow or China jute): This takes good dye and is extensively grown in China.
- (ii) Bombax malabaricum Syn. B. ceiba (Semal or Kapok or silk cotton tree).

Woolly fibres from pericarp of fruits are source of **Kapok** or **Semal** or Silk cotton.

- (iii) Gossypium arboreum, G. herbacium, G. hirsutum (cotton): Cotton fibres are long hairs from seed epidermis.
 - (iv) Hibiscus canabinus (Patsan or Deccanhemp)

(2) Food plants

(i) Abelmoschus esculentus Syn. Hibiscus esculentus (Lady's finger or bhindi or Okra): Young fruits are used as favourite vegetable.

(3) Ornamental plants

- (i) Malva sylvestris (Mallow): An annual plant with purple rose flowers, is grown in gardens.
- (ii) Althaea rosea (Hollyhock or Gulekhera): Beautiful pink or red flowering plant.
- (iii) Hibiscus rosa-sinensis (China rose or shoe-flower or gurhal): This is grown extensively as an ornamental plant with red or pink flowers.

Cucurbitaceae

Systematic position

Division

Angiospermae

Class

Dicotyledonae

Subclass

Polypetalae

Series

Calyciflorae

Order

Passiflorales

Family

Cucurbitaceae

Habit: These are trailing or climbing annuals or perennial herbs. Rarely they are shrubs (e.g., Acanthosicyos) or trees (e.g., Dendrosicyos).

Stem : Herbaceous, branched, pentangular, fistular, tendrils in axil of leaf or opposite to leaves. The morphological nature of tendril is of dispute.

Leaves : Leaves are cauline and ramal. They are alternate, exstipulate, simple, petiolate and cordate (e.g., Cucurbita maxima, Coccinia grandis) or deeply palmately lobed (e.g., Luffa cylindrica, Cyclanthera pedata). Venation is reticulate multicostate.

Inflorescence: Flowers are either solitary axillary (e.g., Cucurbita, Coccinia) or in cymose clusters (e.g., Cucumis, male flowers of Luffa).

Most of the members of the Cucurbitaceae are monoecious but a few are dioecious (e.g., Coccinia cordifolia, Trichosanthes dioica).

Flower: Flowers are bracteate or ebracteate, pedicellate, unisexual, incomplete actinomorphic, pentamerous and epigynous. *Schizopepon* is the only exception which has bisexual flowers.

Male flower

Calyx: Sepals 5, gamosepalous, quincuncial aestivation.

Corolla: Petals 5, gamopetalous, campanulate or rotate, imbricate or valvate aestivation.

Androecium : Stamens 5, polyandrous as in *Fevillea*, or (2)+(2)+1 as in *Momordica*, anthers twisted, alternate to petals, sometimes epipetalous, dehiscence longitudinal.

Gynoecium: Absent.

Female flower

Calyx: Similar to male flower.

Corolla: Similar to male flower.

Androecium : Absent but sometimes 2, 3 or 5 staminodes present.

Gynoecium : Tricarpellary, syncarpous, unilocular, ovary inferior, numerous ovules, parietal placentation but looks as axile placentation, style is simple, stigma 3.

Fruit: Pepo (variation of berry).

Seeds: Exalbuminous.

Female flower: Br or $Ebr \oplus QK_{(5)} C_{(5)} A_0 \overline{G_{(3)}}$

Fig: 2.1-26 Floral diagram of Cucurbitaceae (Cucurbita maxima / Kaddu) (a) Floral diagram of male flower (b) Floral diagram of female flower

Economic importance of family

(1) Medicinal plants

- (i) Coccinia indica (Kandoori): Extracts of root, leaf and fruit are used in treatment of diabetes.
- (ii) Citrullus colocynthis (Indrayan): Colocynthis alkaloid is obtained from its fruits, which is used in treatment of snake bite, rheumatism, etc.
- (iii) Ecballium elatarium: Elatarium is obtained from fruits, which is used in treatment of hydrophobia and malaria.

(2) Vegetables

- (i) Cucurbita maxima (Great pumpkin or Vilayati Kaddu or Red pumpkin).
 - (ii) C. moschata (Pumpkin or Sitaphal)
 - (iii) C. pepo (Field pumpkin or Safed kaddu).
 - (iv) Citrullus vulgaris var. Fistulosus (Tinda or Dil pasand).
 - (v) Lagenaria vulgaris (Bottle gourd or Lauki).
- ☐ Hollow, dried fruits of Lagenaria siceraria are used for making 'beens' (musical instruments) by snake charmers or 'saperas'.
 - (vi) Luffa cylindrica syn. L. aegyptica (Bath sponge or Ghia tori).
 - (vii) L. acutangula (Kali tori).
 - (viii) Momordica charantia (Bitter gourd or Karela).
 - (ix) Trichosanthes anguina (Snake gourd or Chichinda).
 - (x) T. dioica (Pointed gourd or Parwal).

(3) Fruits

- (i) Cucumis melo (Kharbooza).
- (ii) Cucumis sativus (Cucumber or Khira).
- (iii) Cucumis utilissimus (Kakri).
- (iv) Cucumis melo var. momordica (Phunt).
- (v) Citrullus vulgaris (Water melon or Tarbooz).
- (vi) Benincasa hispida (Ash gourd, Wax gourd or White gourd or Petha) – Famous sweet 'Petha' is prepared from it.
 - ☐ Hollow dried fruits are used for making 'Sitar'

Compositae (Asteraceae)

Systematic position

Division : Angiospermae
Class : Dicotyledonae
Subclass : Gamopetalae
Series : Inferae
Order : Asterales

Family : Compositae (Asteraceae)

(Largest family among the angiosperms)

Habit: Most of the plants are annual herbs (e.g., Chrysanthemum, Lactuca, Calendula, Helianthus, Tagetes). A few are shrubs (e.g., Artemisia, Pluchea lanceolata) or rarely trees (e.g., Vernonia arborea, Wilkesia, Leucomeris). Milkamia cordata is a twiner.

Root: Usually there is a tap root, but in *Dahlia* and *Taraxacum officinale* fasciculated roots are present.

Stem: Stem is usually herbaceous, erect, branched, solid, fibrous and sometimes with milky latex. In Jerusalem artichoke (*Helianthus tuberosus*) the stem is underground and tuberous. In *Baccharis*, it is winged like a leaf.

Leaves: Leaves are mostly alternate and occasionally opposite (e.g., Helianthus) or whorled (e.g., Eupatorium, Zinnia verticillata). They are exstipulate, petiolate, simple, pinnately or palmately lobed or compound (e.g., Dahlia, Cosmos). Venation is reticulate.

Inflorescence : Inflorescence is capitulum or head with an involucre of bracts at its base. The number of flowers in each inflorescence varies from 1000 (in large flowers of *Helianthus*) to 1 (in *Echinops*). Peduncle flat on which florets are attached.

Flower: Epigynous, usually pentamerous with reduction in certain whorls, hermaphrodite or unisexual complete or incomplete, tubular (actinomorphic) or ligulate (zygomorphic), bracteate or ebracteate.

(1) Ray florets: Towards periphery of head, sessile bracteate, pistillate or neutral, zygomorphic, ligulate, epigynous.

Calyx: Absent or hairy pappus or scaly, persistent.

Corolla: Petals 5, gamopetalous, ligulate, strap shaped.

Androecium: Absent.

Gynoecium : Bicarpellary, syncarpous, ovary inferior, unilocular, one ovule in each locule, basal placentation, style simple narrow, stigma branched.

(2) **Disc florets**: In the centre of head, bracteate, bisexual, actinomorphic, tubular, pentamerous, epigynous.

Calyx: Absent or pappus.

Corolla: Petals 5, gamopetalous, tubular.

Androecium : 5 stamens, epipetalous, syngenesious, dithecous, bilobed, introrse, filament free.

Gynoecium : Bicarpellary, syncarpous, ovary inferior, unilocular, single ovule in the locule, basal placentation, style single, short, stigma bifid.

(3) **Neutral florets**: Androecium and gynoecium both are absent. Remaining structures are similar to ray floret and disc florets.

Fruit: Cypsella.

Seed: Exalbuminous.

Floral formula:

Disc florets: $Br.\% or \oplus \mathcal{Q}^r K_0 or PC_{(5)} A_{(3)} \overline{G_{(2)}}$

Neutral florets: % or $\oplus K_0 C_{(5)} A_0 G_0$

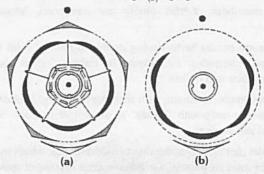

Fig : 2.1-27 Floral diagram of Compositae (*Helianthus annuus*) (a) Ray floret, (b) Disc floret

Economic importance of the family

(1) Sources of medicines

- (i) Arnica montana: This plant yields 'Arnica', which is used as hair vitalizer.
- (ii) Eclipta prostrata (bhringraj) : Its extract is used as hair tonic.
- (iii) Artemisia cina or A. maritima (worm weed): A wormicide (anthelmintic) 'Santonin' is obtained from dried unopened flower heads, which is used as vermifuge or in expelling the intestinal worms.
- (iv) Taraxacum officinale (Common dendelion): Drug 'Taraxacum' obtained from roots and rhizomes is used as laxative and liver tonic.
- (v) Calendula officinalis: 'Calendula' drug obtained from dried ligulate florets is used in sprains.

(2) Sources of food

- (i) Lactuca sativa (Garden lettuce or Salad): This is a salad crop and leaves provide a valuable salad throughout the world.
- (ii) Cichorium intybus (Chicory or Kasni): Roots are source of 'Chicory powder', which is used for blending coffee.
- (iii) Helianthus tuberosus (Jerusalem artichoke or Hathichuk): The tubers are source of food or vegetable (having plenty of Inulin).

(3) Sources of oils

- (i) Carthamus tinctorius (Safflower or Kusum): Seeds yield oil which is edible and because it has percentage of unsaturated fatty acid, so it very good for heart patients.
- (ii) A red dye 'Kusum' is also obtained from its flowers, which is used in foods as well as clothes.

(4) Sources of rubber

- (i) Taraxacum kok-saghyz (Russian dendelion): Roots contain latex, which is the source of 'Dendelion rubber.'
- (ii) Parthenium argentatum In America, Guayule rubber, is obtained from this plant, because 'caoutchouc' granules are present in plant body.

(5) Sources of insecticide

(i) Chrysanthemum marschallii and C. cinerariaefolium (Guldaodi): Flower heads are source of a commercial insecticide 'Pyrethrum'.

(6) Ornamentals

- (i) Calendula officinalis (Pot marigold)
- (ii) Chrysanthemum sps. (Guldaodi)
- (iii) Tagetes sps. (Marigold or Genda)
- (iv) Helianthus annuus (Sunflower).

Gramineae or Poaceae

The members of this family are commonly known as 'grasses'.

Plants are mostly herbs having stem with marked solid nodes and hollow internodes, i.e., **stem is culm.** Further stem is generally circular and hollow.

Leaves simple, alternate, with sheating bases and ligulate (i.e., a membranous outgrowth 'ligule' is present at junction of leaf sheath and leaf lamina).

Spikelet (not flower) is the unit of inflorescence, which may be arranged in spike or panicle, i.e. inflorescence is spike of spikeletes or panicle of spikelets.

Each spikelet is having 1-5 flowers on a reduced axis, which bear two leaf like structures (glumes) at base.

Each flower is in axil of other like structure called 'lemma' (bract). On the flower axis is another leaf-like structure called palea (bracteole). Above palea are two scale like lodicules (perianth).

Flower is hypogynous and zygomorphic.

Perianth reduced and represented by lodicules.

Generally 3 statments with dithecous and versatile anthers.

Carpel is generally 1, unilocular ovary with basal placentation, 2 long styles ending in **feathery stigmas**.

Fruit is **karyopsis** or **grain** (single seeded indehiscent fruit, in which seed coat fuses with fruit wall to form husk).

Fig: 2.1-28 Floral Diagram of Triticum aestivum (Wheat)

(1) Cereals and millets

Most important source of food in the world is cereals having karyopsis or grain fruit, e.g., Triticum vulgare (Wheat), Zea mays (Maize), Oryza sativa (Rice), Avena sativa (Oat), Hordeum vulgare (Barley).

Small sized grains constitute millets, which also provide food, e.g., Sorghum, vulgare (Jawar), Pennisetum typhoides (Bajra), Eleucine coracana (Ragi or Mandua).

- (2) Source of Sugar : Saccharum officinarum (Sugar cane)
- (3) Other plants
- (i) Dendrocalamus sps : Both (i) and (ii) provide bamboo
- (ii) Cynodon dactylon (Doob grass): Fodder.
- (iii) Andropogon muricatus (Khas): Roots provide khas oil.

Tips & Tricks

- Culms: Their nodes and internodes are extremely clear; internodes are hollow, e.g., Bambusa.
- Roots arising from callus in tissue culture are adventitious.
- Life of root hairs is hardly one week. During transplantation, root hairs are shed and therefore, plant remains wilted for sometime till the formation of new root hairs.
- Roots provide more than 50% of total food.
- Acaulescent. Having a reduced stem.
- Allyl sulphide. Characteristic smell of Onion and Garlic.
- The anticancerous substance in garlic is gernium.
- Stem is quadangular in Ocimum, triangular in Cyperus, ribbed in Cucurbits and flat in Cactus.
- Petiole develops last in the leaf.
- CTC tea leaves are rich in iron because they are cured in iron pans.
- Plant with single leaf is Monophyllea.
- Plant with two leaves only in Welwitschia.
- Smallest leaf: Wolffia.
- Broadest leaf: Victoria amazonica (diameter 5 to 6 feet).
- Longest leaf: Raphia vinifera (30 to 50 feet).
- \angle Largest leaf: Victoria regia is the largest leaf of plant kingdom, which are 4m in radius and diameter is 1.5 1.8 m.
- Anisophily: Presence of 2 types of leaves on same node of the plant of Boerhaavia.
- Belt's corpuscles, glands producing edible materials at the apices of leaflets in Acacia sphaerocephala.
- Spike is most common inflorescence.
- Capitulum (racemose head) is most evolved/highly advanced.
- ∠ Longest inflorescence : Agave (12m), amorphophallus (5.5m), puyaraimondii (10 metres).
- Cauliflory: The condition of developing flowers on the main stem (trunkiflory) or older branches from old or persisting axillary buds is called cauliflory. e.g., Ficus.
- S Intersexual: Perfect hermaphrodite, androgynous or monoclinous flower.
- Trioecious: Three types of plants male, female and monoecious, e.g., Silence.
- Style and stigma of saffron (crocus) are edible and source of kesar.
- Ripeness of a flower depends on minimum number of leaves.
- Heterostyly: In this condition, stamens, style and stigma are of different heights. e.g., Primula, Oxalis.
- Plants of tropics bear naked buds i.e., buds without covering.
- Recalcitrant seeds: The seeds get killed on reduction of moisture and exposure to low temperature. e.g., Tea, Jack fruit.
- Orthodox seeds: The seeds which can be stored for long as they tolerate reduction in moisture content (upto 5%) exposure to

low temperature and anaerobic conditions, e.g., Legumes, cereals.

- Smallest seed is of Orchis (wt. 0.004 g) and 1 gram contains 20 lakh seeds.
- Largest seed is Double coconut (Fresh wt. 6 kg).
- Seeds constitute 70% of our diet.
- Largest fruit / Largest seed is Lodoicea maldivica.
- All modern classifications are based on evolution, genotypes and ecological characters. They are phylogenetic in nature.
- Presence of myrosin enzyme is chief feature of family brassicaceae.

Root

- If a primary root continues to grow, the type of root system will be known as [NCERT; DUMET 2009]
 - (a) Secondary

(b) Fibrous

(c) Tap

- (d) Stilt
- 2. Pneumatophores occur in plants of [CBSE PMT 2000]
 - (a) Sandy soil
- (b) Saline marshy soil
- (c) Marshy soil
- (d) Water
- 3. Roots developing from plant parts other than radical are
 - [NCERT; Chd. CET 1997; HPMT 2005]
 - (a) Epiphyllous
- (b) Epicaulous
- (c) Adventitious
- (d) Fibrous
- In which the pneumatophores are found
 - [NCERT; BVP 2001; AMU (Med.) 2009]
 - (a) Tinospora
- (b) Pinus
- (c) Rhizophora
- (d) None of these
- Outer covering of epiphytic root is

[CPMT 2001; Odisha JEE 2005]

- (a) Osmophore
- (b) Rhizophore
- (c) Velamen
- (d) Pneumatophore
- Which of the following is correctly matched [AIIMS 2012]
 - (a) Monstera Fibrous root
 - (b) Dahlia Fasciculated root
 - (c) Azadirachta Adventitious root
 - (d) Basil Prop roots
- 7. Conical fleshy roots occur in
 - (a) Sweet potato
- (b) Dahlia
- (c) Asparagus
- (d) Carrot
- Napiform roots are recorded from
 - (a) Radish
- (b) Carrot
- (c) Beet Fusiform roots are found in
- **IBHU 19961**
- (a) Solanum tuberosum

(d) Sweet potato

(b) Calocasia

- (c) Daucus carota
- (d) Raphanus sativus
- A fibrous root system is better adapted than tap root system for IBHU 1993, 2001: AMU (Med.) 2001; DUMET 2009]
 - (a) Storage of food
 - (b) Anchorage of plant to soil
 - (c) Absorption of water and minerals
 - (d) Transport of water and organic food

11. Stilt roots are reported from [Bihar PMT 1994;

[AMU (Med.) 2010]

- BHU 1996: Odisha JEE 1997, 20121 (a) Pandanus (Screw Pine)
- (c) Mango-ginger
- (b) Radish
- (d) Bryophyllum 12. Assimilatory (Photosynthetic) roots a characteristic of
 - [Kerala CET 2000; BHU 2012]
 - (a) Trapa and Tinospora
 - Taeniophyllum and Podostemon (b)
 - Both correct (c)
 - (d) None of these
- Root cap is largest in 13.
 - (a) Banyan
- (b) Pandanus
- (c) Jussiaea
- (d) Maize
- Find the incorrect match
- (a) Tap root : Carrot
- (b) Adventitious root: Sweet potato
- (c) Prop root : Banyan tree
- (d) Stilt root: Turnip
- 15. A root is adventitious when it is [CPMT 2002; RPMT 2005]
 - (a) Swollen
 - (b) Growing in marshy places
 - (c) Formed from plumule
 - (d) Modified for storage
- 16. Monocot plants are characterized by the presence of

[NCERT; J & K CET 2005]

- (a) Tap roots
- (b) Fibrous roots
- (c) Annulated roots
- (d) Stilt roots
- 17. Nodulated roots bearing family is [RPMT 1993, 95, 96] (a) Mimosoideae (b) Caesalpinoideae
 - (c) Papilionatae
- (d) Solanaceae
- Clinging and epiphytic roots are found in [CBSE PMT 1999]
 - (a) Orchid
- (b) Tinospora / Trapa (d) Pothos / Podostemon
- (c) Rhizophora / Pandanus
- 19. Roots are absent in
 - (a) Myriophyllum
- (b) Ceratophyllum
- (c) Utricularia and Wolffia
- (d) All of these
- Stilt roots which grow obliquely from basal nodes of culm stem and acting as brace are found in
 - [NCERT; MP PMT 1993; DPMT 1999]
 - (a) Sorghum
- (b) Maize
- (c) Sugarcane
- (d) All of these
- In Ipomoea batatas/Sweet potato the food is stored in
 - [Bihar PMT 1994; JKCMEE 2002]
 - (a) Root tuber
- (b) Stem tuber
- (c) Bud
- (d) Leaves
- In maize, the fibrous roots develop from
 - (b) Upper nodes
 - (a) Lower nodes (c) Upper internodes
- (d) None of the above

INCERTI

- 23. Select the correct statements
 - (A) From the region of elongation, some of the epidermal cells for root hairs
 - (B) Pneumatophores are seen in Rhizophora
 - (C) Adventitious roots are seen in the Banyan tree
 - (D) Maize and sugarcane have prop roots

[NCERT; Kerala PMT 2011]

- (a) (A) and (D)
- (b) (A), (C) and (D)
- (c) (C) and (D)
- (d) (B) and (C)
- (e) (A), (B) and (D)

Regions of root from base to root tip are 24.

23.	Eye of potato is		[NCERT;	30.	Sie			
			1; CBSE PMT (Pre.) 2011]					FMC 1994; Manipal 1997]
	(a) Apical bud		Axillary bud			Wheat	100000	Groundnut
0.4	(c) Accessory bud		Adventitious bud		(c)	Radish	(d)	Ginger
24.	Which of the following	is not relat		37.	Pri	ckles of Rose are		
	(a) Tunic	(b)	[Kerala CET 2001] Lateral buds		(a)	Modified leaves	(b)	Modified stipules
	(c) Nodes	10 10	Scale leaves		(c)	Exogenous in origin	(d)	Endogenous in origin
	1-1	1/						

38. Match the following and select the correct combination from the options given below

(5	Column I item Modifications)	Column II (Found in)		
A.	Underground stem	1.	Euphorbia	
B.	Stem tendril	2.	Opuntia	
C.	Stem thorns	3.	Potato	
D.	Flattened stem	4.	Citrus	
E.	Fleshy cylindrical stem	5.	Cucumber	

[NCERT; Kerala PMT 2011]

- (a) A-1, B-2, C-3, D-5, E-4
- (b) A-2, B-3, C-4, D-5, E-1
- (c) A-3, B-4, C-5, D-1, E-2
- (d) A-3, B-5, C-4, D-2, E-1
- (e) A-5, B-3, C-4, D-1, E-2
- 39. Bulbil is a modification of
- - (a) Underground stem
- (b) Bases of leaves
- (c) Buds
- (d) Radicle

40. Which of the following is not a stem modification

[NEET (Phase-I) 2016]

- (a) Pitcher of Nepenthes
- (b) Thorns of citrus
- Tendrils of cucumber
- (d) Flattened structures of Opuntia
- In humid climate, presence of spines in shrubs is
 - (a) To reduce transpiration
 - (b) To defend against mammal herbivory
 - (c) To defend against wood cutters
 - (d) To check seed predation by birds
- 42. In onion leaves food is stored in the form of
 - (a) Sugar
- (b) Starch
- (c) Protein
- (d) Malic acid
- The cloves which are used in food preparation are

[Kerala CET 2005; Odisha JEE 2010]

- (a) Seeds
- (b) Leaves
- (c) Flower buds
- (d) Stem tip
- (e) Terminal bud
- Rhizomes are mostly

[AFMC 1999]

- (a) Sympodial
- (b) Diageotropic
- (c) Horizontal
- (d) All of these
- 45. Tip of twiner is sensitive and coils around support itself. This coiling is called
 - (a) Nutation
- (b) Vernation

(b) Stem

(c) Epinasty

(a) Root

- (d) Circination
- 46. Multicellular hairs are found on
- [MHCET 2004]
- (c) Both (a) and (b)
- (d) None of the above
- 47. Potato and sweet potato
- [AIIMS 2004]
- (a) Have edible parts which are homologous organs
 - (b) Have edible parts which are analogous organs
- (c) Have been introduced in India from the same place
- (d) Are two species of the same genus

48. Which of the following plants have long slender and coiled stem tendrils developed from axillary buds

[NCERT; Kerala PMT 2011]

- (a) Grapevine and pumpkins
- (b) Australian Acacia and watermelon
- (c) Bougainvillea and cucumber
- (d) Strawberry and grapevine
- (e) Alstonia and pumpkins
- Aroids store food in 49.
 - (a) Inflorescence
- (b) Enlarged root
- (c) Leaf bases
- (d) Swollen stem
- Which one of the following pairs is wrongly matched while the remaining three are correct [CBSE PMT (Mains) 2011]
 - (a) Bryophyllum-Leaf buds (b) Agave Bulbils
 - (c) Penicillium Conidia
- (d) Water hyacinth Runner
- Stem modified for photosynthetic function by appearing like 51. leaves are known as [NCERT; AFMC 1996; JIPMER 1998; JKCMEE 2002; MP PMT 2013; NEET (Phase-I) 2016]

Leaves are changed into spines in xerophytic structures

Called

[CPMT 1996; Kerala PMT 2004]

- (a) Phyllode
- (b) Phylloclade
- (c) Cladode
- (d) Tendril
- Which one of the following statements is not correct

[NEET (Phase-II) 2016]

- (a) Water hyacinth, growing in the standing water, drains oxygen from water that leads to the death of fishes
- (b) Offspring produced by the asexual reproduction are called clone
- (c) Microscopic, motile asexual reproductive structures are called zoospores
- (d) In potato, banana and ginger, the plantlets arise from the internodes present in the modified stem

Leaf

- 1. Petiole part of the leaf is known as
- [Odisha JEE 2012]
 - (a) Epipodium
- (b) Mesopodium
- (c) Hypopodium
- (d) None of these
- 2. A leaf is identified from
- [JKCMEE 1999]

[AMU (Med.) 2010]

- (a) Flat green lamina
- (b) Presence of leaf blade and petiole
- (c) Presence of axillary bud
- (d) Occurrence of chlorophyll
- 3. Find the correct match
 - (a) Mustard plant : leaves are opposite
 - (b) Mustard plant : leaves are alternate
 - (c) Guava plant: Leaves are alternate
 - (d) Guava plant: Leaves are whorled
- Finely dissected leaves occur in
 - (a) Free floating plants
 - (b) Rooted floating leaved plants
 - (c) Submerged plants
 - (d) Emerged plants

BOOK DE	POT 1960		
5.	In Tamarind (Imli) the pinnate leaf is [Bihar PMT 1994]	18.	Tendrillar stipules occur in [DPMT 1999]
	(a) Tripinnate (b) Bipinnate		(a) Dolichos lablab (b) Acacia
	(c) Paripinnate (d) Imparipinnate		(c) Smilax (d) Mango
6.	Presence of sheathing leaf base and ligule are characteristic	19.	The leaves are modified into tendrils, hooks, pitcher and
	of [NCERT; Chd. CET 1997]		bladder in the following plants respectively [Kerala PMT 2006]
	(a) Cycas leaf (b) Fern leaf		(a) Sweet pea, Cat's nail, Nepenthes, Utricularia
	(c) Banana leaf (d) Grass leaf		
7.	Approximate diameter of Victoria leaf is [BHU 1996]		(b) Sweet pea, Cat's nail, Utricularia, Nepenthes
	(a) 1m (b) 1.3m		(c) Nepenthes, Cat's nail, Sweet pea, Utricularia
	(c) 2m (d) 3m		(d) Nepenthes, Sweet pea, Cat's nail, Utricularia
8.	A dicotyledenous plant showing parallel venation is (a) Dioscorea (b) Smilax		(e) Utricularia, Nepenthes, Cat's nail, Sweet pea
	(c) Calophyllum (d) Hibiscus	1100	
9.	Bipinnate leaves are characteristic of	20.	Onion stores food in
	(a) Cruciferae (b) Solanaceae		(a) Underground stem (b) Fleshy scales
	(c) Papilionoideae (d) Mimosoideae		(c) Root (d) Shoot
10.	In Lathyrus aphaca, the leaves are modified into	21.	Study the following statements and select the correct option
	[AIIMS 1997]	21.	
	(a) Spine (b) Tendril		(A) Buds are present in the axil of leaflets of the compound
	(c) Scale (d) Stem-like structure		leaf
11.	Foliaceous stipules are found in [Odisha JEE 2012]		(B) Pulvinus leaf-base is present in some leguminous plants

Arrangement of floral leaves in a floral bud is called

[Pb. PMT 1997]

- (a) Vernation
- (b) Prefoliation
- (c) Aestivation
- (d) Ptyxis
- Phyllode is found in

INCERT:

Chd. CET 2003; CBSE PMT (Pre.) 2012]

- (a) Clematis
- (b) Gloriosa
- (c) Australian Acacia
- (d) Dischidia
- Match the columns 48.
 - (i) Acicular
- (1) Grass
- (ii) Linear
- (2) Nerium
- (iii) Lanceolate
- (3) Banana
- (iv) Oblong
- (4) Pine

Options

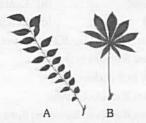

[AMU (Med.) 2002]

- (a) (i) 4 (ii) 1 (iii) 2 (iv) 3
- (b) (i) 4 (ii) 1 (iii) 3 (iv) 2
- (c) (i) 4 (ii) 2 (iii) 3 (iv) 1
- (d) (i) 4 (ii) 3 (iii) 2 (iv) 1
- Spiral phyllotaxy in which sixth leaf lies above the first one 49. [APMEE 2002] after completing two circles is
 - (a) Distichous
- (b) Tristichous
- (c) Pentastichous
- (d) Octastichous
- Ochreate stipules occur in leafy vegetable

[APMEE 2002]

- (a) Amaranthus
- (b) Mentha
- (c) Platanus
- (d) Rumex
- The arrangement and folding of each lamina without any 51. relationship with other leaves in bud, is called [DPMT 1997]
 - (a) Ptyxis
- (b) Vernation
- (c) Aestivation
- (d) Phyllotaxy
- In spiral phyllotaxy, the number of leaves at each node is 52.
 - (a) One
- (b) Two
- (c) Many
- (d) Three

53.

See the following figures and identify leaves A and B

INCERTI

- (a) A Palmately compound leaf, B Palmately compound leaf
- (b) A Pinnately compound leaf, B Pinnately compound leaf
- (c) A Palmately compound leaf, B Pinnately compound leaf
- (d) A Pinnately compound leaf, B Palmately compound leaf
- In Banana, true stem is underground. The stem like structure 54. outside soil is formed by
 - (a) Peduncle
- (b) Petiole of leaves
- (c) Leaf bases
- (d) Overlapping of leaves
- In Calotropis the phyllotaxy is 55.
 - (b) Verticellate
 - (a) Alternate

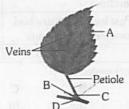

- (c) Opposite and superposed (d) Opposite and decussate
- 56. Leaf blade is spinous in case of
- [Manipal 2005]

[AMU (Med.) 2009]

- (a) Nerium
- (b) Zizipus
- (c) Argemone
- (d) Cannabis

- 57. 120° phyllotaxy is found in
- [Odisha JEE 2011]

- (a) Tristichous
- (b) Distichous
- (c) Pentastichous
- (d) Octastichous
- How many plants among China rose, Ocimum, sunflower, mustard, Alstonia, guava, Calotropis and Nerium (Oleander) have opposite phyllotaxy [NEET (Karnataka) 2013]
 - (a) Three
- (b) Four
- (c) Five
- (d) Two
- See diagram of a typical leaf. In which of the following option all the four parts marked as A, B, C and D are [NCERT] correctly identified

	A	В	C	D
(a)	Leaflet	Axillary bud	Stipule	Leaf base
(b)	Lamina	Axillary bud	Stipule	Pedicel
(c)	Lamina	Stipule	Axillary bud	Leaf base
(d)	Lamina	Axillary bud	Stipule	Leaf base

Inflorescence

1. Match List I with List II and select the correct option

ni g	List I	List II		
A.	Spike	1.	Bougainvillea	
3.	Capitulum	2.	Coleus	
C.	Dichasial cyme	3.	Adhatoda	
D.	Multiparous cyme	4.	Zinnia	
E.	Verticillaster	5.	Asclepias	

[Kerala PMT 2005, 08]

- (b) A-3, B-1, C-4, D-5, E-2
- (c) A-2, B-4, C-1, D-5, E-3
- (d) A-4, B-2, C-5, D-1, E-3
- (e) A-5, B-4, C-1, D-3, E-2
- Find out the correct sequence of labelling of diagram given [Kerala PMT 2006] below

(a) A - spike, B - raceme, C - dichasial cyme, D monochasial cyme

(b) A - raceme, B - spike, C - monochasial cyme, D dichasial cyme

(c) A - dichasial cyme, B - monochasial cyme, C - raceme, D - spike

(d) A - spike, B - dichasial cyme, C - monochasial cyme, D- raceme

(e) A - raceme, B - dichasial cyme, C - spike, D monochasial cyme

UNIVERSAL BOOK DEPOT 1960

[Kerala PMT 2009]

[BVP 2002]

 Select the correct pair of answers in which the former represents the set of characters present in *Poinsettia* and the latter in the pair represents the set of characters present in Casuarina

Study the following table

(i) •	Modified aerial stem	Unisexual flowers develop acropetally	Chalazal entry of pollen tube		
(ii)	Flowers achlamydeous	Pedicels of the all flowers are of same length	Presence of false whorl		
(iii)	Cohesion of bracts forming a cup	Centrifugal opening of flower	Male flowers many		
(iv)	Flower formation on one side in a spiral manner	Presence of rachilla	Terminal part of the peduncle is flowerless		

[EAMCET 2009]

- (a) (ii), (iii)
- (b) (i), (ii)
- (c) (iv), (iii)
- (d) (iii), (i)
- 4. In cyathium inflorescence

[Kerala CET 2005; Odisha JEE 2010]

- (a) Single male flower is surrounded by female flowers
- (b) Male and female flowers are borne in different plants
- (c) There is of one male and one female flowers
- (d) Single female flower surrounded by many peripheral male flowers
- The most advanced type of inflorescence is
 - (a) Corymb
- (b) Catkin
- (c) Spadix
- (d) Capitulum
- A student observed 34 inflorescences in Bougainvillea and 42 inflorescences in Poinsettia. Find out the number of flowers in Bougainvillea and the number of female flower in Poinsettia, respectively [EAMCET 2009]
 - (a) 34, 126
- (b) 68, ∞
- (c) 204, 164
- (d) 102, 42
- The flowers in the raceme/racemose are arranged

IPb. PMT 20001

- (a) Acropetally
- (b) Basipetally
- (c) Centripetally
- (d) Centrifugally
- 8. Which of the following statements are correct
 - When a fruit develops from the inflorescence, it is composite
 - (ii) Mesocarp is the edible part in apple
 - (iii) Gynobasic style is seen in Ocimum
 - (iv) Hypanthodium is a special type of inflorescence found in Euphorbia species [Kerala PMT 2009]
 - (a) (i) and (iv) are correct
 - (b) (i) and (iii) are correct
 - (c) (i) and (ii) are correct
 - (d) (ii), (iii) and (iv) are correct
 - (e) (ii) and (iv) are correct
- Amentum (Catkin) inflorescence is found [JIPMER 1996]
 - (a) Mulberry (Morus)
- (b) Poplulus (Poplar)
- (c) Acalypha (Cats tail)
- (d) All of these

Characteristic inflorescence of family compositae sunflower is [JIPMER 2000; BHU 2000; CPMT 2004]

- (a) Capitulum
- (b) Cymose head
- (c) Catkin
- (d) Spadix
- 11. Given inflorescence is a
 - (a) Cyathium
 - (b) Dichasial cyme
 - (c) Umbel
 - (d) Panicle
 - (e) Verticillaster
- The whorl of bracts present below the inflorescence of Helianthus (sunflower) is [Pb. PMT 2000]
 - (a) Involucre
- (b) Involucel
- (c) Stipule
- (d) Bract
- 13. Cymose inflorescence is present in

[NCERT; CBSE PMT (Pre.) 2012]

- (a) Solanum
- (b) Sesbania
- (c) Trifolium

(a) Thalamus

- (d) Brassica
- 14. Hypanthodium is a specialized type of
 - (b) Ovary
 - (c) Fruit
- (d) Inflorescence
- 15. Inflorescence in Musa paradisiaca (banana) is a

[AMU (Med.) 2002; J & K CET 2010]

- (a) Raceme
- (b) Catkin
- (c) Spadix
- (d) Verticellaster
- 16. The unit of inflorescence in grasses / gramineae (poaceae) is

[BVP Pune 1998; Odisha JEE 2012]

- (a) Thyrsis
- (b) Spike
- (c) Spikelet
- (d) Raceme
- 17. The capitulum type of inflorescence is found in
 - [J & K CET 2005]
 - (a) Marigold
- (b) Salvia
- (c) Euphorbia
- (d) Jasmine
- 18. In China rose, the inflorescence is
 - ce is
 - (a) Cymose (c) Racemose
- (b) Capitulum (d) Solitary cyme
- 19. Consider the following statements
 - (A) In racemose inflorescence the flowers are borne in a basipetal order
 - (B) Epigynous flowers are seen in rose plant
 - (C) In brinjal the ovary is superior

Of these statements

[Kerala PMT 2010]

[MHCET 2004]

- (a) (A) and (B) are true but (C) is false
- (b) (A) and (C) are true but (B) is false
- (c) (A) and (B) are false but (C) is true
- (d) (A) and (C) are false but (B) is true
- (e) (B) and (C) are true but (A) is false
- The edible part of cauliflower is [CPMT 2004; AFMC 2005]
 - (a) Mesocarp
- (b) Cotyledons
- (c) Endosperms
- (d) Inflorescence
- 21. In 'Tulsi' (Ocimum) of labiatae the inflorescence is
 - (a) Cyathium
- (b) Verticillaster
- (c) Hypanthodium
- (d) Raceme of Racemes

UNIVERSAL
BOOK DEPOT 1960

Many plants among Indigofera, Sesbania, Salvia, Allium, [Odisha JEE 2011] The inflorescence in cauliflower is 22. Aloe, mustard, groundnut, radish, gram and turnip have (a) Compound corymb (b) Corymb stamens with different lengths in their flowers (d) Catkin (c) Umbel [NEET (Phase-II) 2016] [KCET 1998, 2000] Cyathium is found in genus 23. (b) Three (a) Six (b) Ficus (a) Croton (d) Five (c) Four (d) Ricinus (c) Euphorbia The special type of inflorescence found in Ficus where the Flower 24 female flower are at bottom and male flower near ostiole Flower is intersexual in and enclosed within a cup shaped fleshy thalamus (b) Cucurbita (a) Date palm (receptacle) with ostiole is called [Manipal 2000; BHU 2002; Pb. PMT 2004; RPMT 2006] (d) Hibiscus (c) Papaya [NCERT; Bihar PMT 1994] (b) Verticillaster (a) Cyathium Thalamus is (d) Hypanthodium (b) Base of ovary (c) Spadix (a) Base of flower An edible inflorescence is (d) Modification of petal (c) Modification of pollen 25. (b) Catkin (a) Corymb [Bihar PMT 1994] Synandrous condition is fusion of 3. (d) All of these (c) Hypanthodium (a) Filaments only Inflorescence with unisexual sessile flower is 26. (b) Both filaments and anthers [AFMC 1996, 2002; AMU (Med.) 1999] (c) Anthers only (b) Spikelet (a) Spike (d) Petals (d) Spadix (c) Catkin Most accurate function in the following statements about A characteristic of angiosperms is 27. [HPMT 1994; Rohtak PMT 1994] [DPMT 1996] inflorescence is (b) Root (a) Dispersal of seeds (a) Flower (d) All of these (b) Formation of more fruit (c) Seed Which of these is an example for zygomorphic flower with (c) Formation of pollen grains [Kerala PMT 2010] (d) Dispersal of pollens imbricate aestivation Inflorescence is edible in Brassica oleracea [AFMC 1998] (b) Mustard 28. (a) Calotropis (b) Var. capitate (a) Var. botrytis (d) Cassia (c) Canna (d) Var. gemifera (c) Var. gongyloides (e) Cucumber A beautiful whorl which encloses whole of the inflorescence is 29. Ligulate/strap-shaped corolla occurs in sunflower in [Manipal 2002] [JIPMER 2000] (b) Spadix (a) Bract (b) Immature florets (a) Disc florets (d) Involucre (c) Spathe (d) Both ray and disc florets (c) Ray florets [NEET (Karnataka) 2013] 30. Inflorescence is racemose in Beauty of Bougainvillea flower is due to 7 (b) Tulip (a) Brinjal [AFMC 1996, 99; BHU 2008] (d) Soyabean (c) Aloe (b) Calyx 31. In a cymose inflorescence the main axis (a) Corolla [NEET (Karnataka) 2013] (d) Androecium (c) Bracts (a) Has unlimited growth Flower is complete when it has (b) Bears a solitary flower (a) Calyx, corolla, androecium and gynoecium (c) Has unlimited growth but lateral branches end in (b) Calyx and corolla flowers (c) Androecium and gynoecium (d) Terminates in a flower (d) Corolla, androecium and gynoecium See the following diagrams and identify inflorescence A and B Keel is the characteristic feature of flower of 9 INCERTI [AIPMT (Cancelled) 2015] (b) Aloe (a) Indigofera (d) Tulip (c) Tomato In monoadelphous condition, stamens have 10. (a) Filaments of all united in one group but anthers are free (b) Filaments united in groups but all anthers are free (c) Anthers are fused but filaments are free

(d) Both anthers and filaments are fused

Stamens attached to petals are

(a) Antipetalous

(c) Epiphyllous

[BHU 1993]

(b) Epipetalous

(d) Episepalous

- (a) A Cymose, B Cymose
- (b) A Racemose, B Racemose
- (c) A Racemose, B Cymose
- (d) A Cymose, B Racemose

20.	On the basis of position of the ovary, mustard plants are		(a) Zygomorphic, epigynous with twisted aestivation
	[J & K CET 2012]		(b) Actinomorphic, hypogynous with twisted aestivation
	(a) Hypogynous (b) Perigynous		(c) Actinomorphic, epigynous with valvate aestivation
	(c) Epigynous (d) Zygomorphic		(d) Zygomorphic, hypogynous with imbricate aestivation
21.	In angiospermic bud condition floral bud is covered by	34.	Versatile anther is attached to filament [BHU 1996]
	whorls of [Odisha JEE 2008]		(a) At top firmly
	(a) Petal (b) Sepal		(b) At base firmly
22.	(c) Anther (d) Stigma		(c) Throughout length
	The most suitable flower for study of floral parts is (a) Rose (b) Sunflower		(d) About middle of connective allowing free movement
		35.	Choose the product that is derived from style and stigma
23.			[CBSE PMT 1992]
	In Maize, the flowers are [CPMT 1994] (a) Absent		(a) Saffron (b) Fenugreek
		fine s	(c) Asafoetida (d) Psyllium
	(b) Unisexual but on different plants	36.	Ray florets of sunflower (Compositae) are
	(c) Bisexual		(a) Bisexual (b) Unisexual
17.0	(d) Unisexual but on the same plant		(c) Asexual (d) None of these

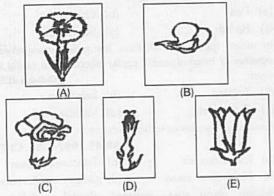

Part of pistil which receives pollen is 37.

[NCERT; MP PMT 2004]

- (a) Ovary
- (b) Style
- (c) Stigma
- (d) Ovule
- An example of axile placentation is 38.

[CBSE PMT 2009; AIPMT 2015]

- (a) Argemone
- (b) Dianthus
- (c) Lemon
- (d) Marigold
- The perianth is the term used when 39.
 - (a) Androecium and gynoecium are similar
 - (b) Androecium and calyx are similar
 - (c) Corolla and gynoecium are similar
 - (d) Calyx and corolla are similar
- The correct sequence of types of corolla in the following 40. [Kerala PMT 2008]

- (a) A Caryophyllaceous, B papilionaceous, C bilabiate, D - tubular, E - bell- shaped
- (b) A papilionaceous, B bilabiate, C tubular, D bellshaped, E - caryophyllaceous
- (c) A bilabiate, B papilionaceous, C- caryophyllaceous, D - bell- shaped, E - tubular
- (d) A caryophyllaceous, B bilabiate, papilionaceous, D - tubular, E - bell- shaped
- (e) A tubular, B bell- shaped, C caryophyllaceous, D - bilabiate, E - papilionaceous
- 41. A flower is zygomorphic when

[WB JEE 2011]

- (a) Any transverse section divides it into two equal halves
- (b) Only one transverse section divides it into two equal halves
- (c) Every vertical section passing through its centre divides it into two equal halves
- (d) Only one vertical section passing through its centre divides it into two equal halves
- Flower is a modified shoot as 42.
 - (a) Thalamus may elongate to show internodes
 - (b) There is aggregation into inflorescence
 - (c) It bears essential organs
 - (d) It may have epicalyx
- Usually, the whorl in a flower that attracts insects and [KCET 2012] protects the essential parts is
 - (a) Calyx
- (b) Androecium
- (c) Gynoecium
- (d) Corolla

When margin of thalamus grows upward enclosing ovary completely and getting fused with it and the other parts of flower arise above the ovary, the flower is said to be

[AMU (Med.) 2012]

- (a) Hypogynous
- (b) Perigynous
- (c) Epigynous
- (d) Inferior
- Smallest flower belongs to 45.
- (b) Wolffia microscopica

[DPMT 2004; CPMT 2009]

- (a) Rosa indica
- (c) Ranunculus scleratus
- (d) Colocasia antiquorum
- Largest flower is that of 46.

[CPMT 1996; BHU 2005; Odisha JEE 2005]

- (a) Sunflower
- (b) Rafflesia
- (c) Nelumbo
- (d) Drosera
- Polyadelphous anthers are present in
 - (a) Sunflower
- (b) Lemon
- (c) Lady's finger
- (d) Peanut
- Flowers of Liliaceae, Malvaceae and Solanaceae are 48.

[RPMT 1994, 96; BHU 1995]

- (a) Hypogynous
- (b) Perigynous
- (c) Epigynous
- (d) Amphigynous
- Flowers and stamens of compositae are 49.
 - (a) Hypogynous and inferior
 - (b) Epigynous and superior
 - (c) Hypogynous and superior
 - (d) Epigynous and inferior
- Compound apocarpous gynoecium is found in 50.

[CBSE PMT 1991]

- (a) Lily
- (b) Hollyhock
- (c) Lotus/Ranunculus
- (d) Pumpkin
- The primitive type of stamens are found in the flowers 51. [AIIMS 1994] family
 - (a) Liliaceae
 - (b) Malvaceae
 - (c) Gramineae/Poaceae
 - (d) Degeneriaceae/Magnoliaceae
- Find out the pairs, which are correctly, matched with respect 52. to aestivation of petals
 - Valvate Calotropis
- II. Twisted Bean
- III. Imbricate- Cassia
- IV. Vexillary- China rose
 - [Kerala PMT 2012]

- (a) II and IV
- (b) I and II
- (c) I and III
- (d) III and IV
- (e) II and III
- Oblique septum and swollen placenta is characteristic 53. feature of
 - (a) Gloriosa superba
- (b) Capsicum frutescence
- (c) Althea rosea
- (d) Dalbergia sissoo
- Ascending imbricate corolla is found in
 - (a) Pisum/Papilionatae
 - (b) Tamarindus/Caesalpinoidae
 - (c) Mimosa/Mimosoidae
 - (d) Datura/Solanaceae

100			ECOK DEPOT 1960
55.	zygomorphic and epigynous flowers. Each flower reveals	67.	When the other floral parts are arranged at the base of the gynoecium, the flower is called [WB JEE 2009]
	dichlamydeous condition with many stamens and multiple fruits with exalbuminous seeds. What is the ratio of		(a) Hypogynous flower (b) Perigynous flower
	advanced and primitive characters in it [EAMCET 2009]	60	(c) Epigynous flower (d) Agynous flower
	(a) 1:2 (b) 2:3	68.	Zygomorphic condition can be represented as
	(c) 1:1 (d) 3:2		[NCERT; CPMT 2009]
56.	Parachute like pappus is found in [JKCMEE 2000]		(a) ⊕ (b) %
	(a) Liliaceae/Cotton (b) Gramineae/Paddy	60	(c) P (d) G
	(c) Compositae/Marigold (d) Solanaceae/Calotropis	69.	Gynoecium with fused carpels [AFMC 2008]
57.	In Gossypium the type of cohesion is [RPMT 1992, 96]		(a) Syncarpous (b) Apocarpous
	(a) Monoadelphous (b) Diadelphous	70	(c) Syngenecium (d) None of these
	(c) Polyadelphous (d) Monothecous	70.	Which of the following is regarded as equivalent to perianth
58.	A plant with actinomorphic and hypogynous flowers,		[AIIMS 1996] (a) Glume (b) Lodicule
	heterochlamydeous perianth, dorsifixed and extrorse		
	anthers dehiscing transversely belongs to [EAMCET 2009]	71	(c) Superior palea (d) Inferior palea
	(a) Coronariae (b) Bicarpellatae	71.	When the anthers mature earlier than the stigma of ones own flower, the condition is known as
59.	(c) Thalamiflorae (d) Calyciflorae		(a) Herkogamy (b) Protandry
33.	A plant has an androecium with monadelphous stamens, monothecous and reniform anthers. The corolla exhibits		(c) Heterostyly (d) Heterogamy
	contorted aestivation. The Plant could be	72.	$A_{1+(9)}$ stands for
	[BHU 1995; KCET 2009]		
	(a) Rauwolfia (b) Vinca		(a) Adelphous (b) Synantherous
	(c) Nerium (d) Hibiscus	-11	(c) Diadelphous (d) None of these
60.	In guava, cucurbits flowers are [WB JEE 2008]	73.	Obdiplostemonous condition is that in which the stamens
	(a) Hypogynous flower		are in two whorls and
	(b) Epigynous flower		(a) Outer whorl is fused to inner whorl
	(c) Perigynous flower		(b) Outer whorl is opposite to petals
	(d) Both hypogynous & perigynous		(c) Inner whorl is opposite to petals
61.	Gynandrous condition means [Odisha JEE 2010]	7.4	(d) Both inner as well as outer whorls are opposite to petals
	(a) Adhesion of stamens and carpels	74.	Choose the specific characters of the flowers of Canna
	(b) Cohesion of stamens		[Kerala PMT 2012]
	(c) Stamens united by filaments only		(a) Actinomorphic and radial symmetry
	(d) Free stamens		(b) Irregular and bilateral symmetry
62.	In floral formula (K) denotes [NCERT; WB JEE 2008]		(c) Irregular and zygomorphic
	(a) Polysepalous (b) Gamosepalous		(d) Irregular and radial symmetry
	(c) Polypetalous (d) Gamopetalous	7-	(e) Irregular and asymmetric
53.	To Which of the following flower' synandrous' condition is	75.	Plants with single whorl of perianth are placed under
	found [WB JEE 2008]		[Kerala PMT 2007]
	(a) Sunflower (Helianthus sp) (b) Gourd (Cucurbita sp)		(a) Class: Monocot Sub class: Monochlamydeae
	(c) Pea (Pisum sativum) (d) Lemon (Citrus sp)		(b) Class: Dicot Series : Monochlamydeae
54.	A monocarpic plant is one which		(c) Class: Dicot Sub class: Monochlamydeae
	[MP PMT 2009; Odisha JEE 2009]		(d) Class: Monocot Sub class: Gamopetalae
	(a) Has only one carpel	76	(e) Class: Dicot Series : Bicarpellatae
	(b) Flowers once in a life-time	76.	In some plants the style is shorter. But in some others, it is longer than the stamens. This condition is called
	(c) Produces only one seed		[MHCET 2003]
	(d) Produces only one fruit		(a) Homogamy (b) Homostyly
55.	The term Anthesis is used for		(c) Heterostyly (d) None of these
	[AIEEE Pharmacy 2004; AFMC 2012]	77.	Which of the following flowers show heterostyle
	(a) Cluster of anthers (b) Opening of flowers		[MHCET 2002, 06]
	(c) Dehiscence of anthers (d) Falling of flowers		(a) Mirabills (b) Hibiscus
6.	Plants having flowers with free petals are placed under		(c) Primrose (d) Pisum
	[VITEEE 2006]	78.	The example for trimerous, unisexual flower is [KCET 2004]
	(a) Polypetalae (b) Monocotyledons		(a) Cocos nucifera (b) Hibiscus
			10/

(c) Tamarind

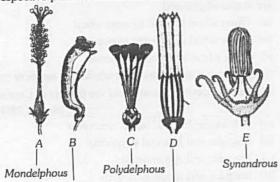

(d) Pea

(d) Monochlamydae

(c) Gamopetalae

- In many cultivated ornamental flowers, number of petal whorls is higher than the one in wild type. Extra petals are [JKCMEE 2000] generally modified
 - (a) Sepals
- (b) Petals
- (c) Stamens
- (d) Pistils
- 80. The corolla of Hibiscus is
- **IMHCET 2002]**
- (a) Gamopetalous, valvate (c) Polypetalous, valvate
- (b) Gamopetalous, twisted (d) Polypetalous, twisted
- Arrangement of sepals and petals in the bud condition is 81. [MHCET 2004, 05] called
 - (a) Ptyxis
- (b) Placentation
- (c) Aestivation
- (d) Phyllolaxy
- Corolla in China rose are 82.
- [MHCET 2004]
- (a) 5, gamopetalous, twisted (b) 5, gamopetalous valvate
- (d) 5, polypetalous contorted (c) 5, polypetalous valvate
- Keel is characteristic of the flower of [CBSE PMT (Pre.) 2010] 83.
 - (a) Bean
- (b) Gulmohur
- (c) Cassia
- (d) Calotropis
- In unilocular ovary with a single ovule the placentation is 84. [NCERT; CBSE PMT (Pre.) 2010]
 - (a) Axile
- (b) Marginal
- (c) Basal
- (d) Free Central
- The following diagrams A, B, C, D and E show the different 85. types of arrangement of stamens based on the cohesion of their parts in different plants. Assign the stamens to their respective plants. Choose the correct answer [KCET 2010]

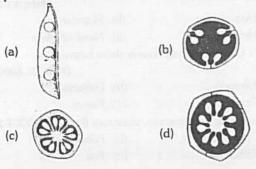

Syngenesious

	A	В	С	D	E
(a)	Hibiscus rosa-sinensis	Helianthus annus	Cucurbita pepo	Crotolaria juncea	Bombax ceiba
(b)	Hibiscus rosa-sinensis	Bombax ceiba	Cucurbita pepo	Crotolaria juncea	Helianthus annus
(c)	Hibiscus rosa-sinensis	Bombax ceiba	Helianthus annus	Cucurbita pepo	Crotolaria juncea
(d)	Hibiscus rosa-sinensis	Crotolaria juncea	Bombax ceiba	Helianthus annus	Cucurbita pepo

Diadelphous

Which one of the following diagrams represents the 86. [CBSE PMT (Mains) 2011] placentation in Dianthus

Flowers are Zygomorphic in 87.

INCERT;

CBSE PMT (Pre.) 2011]

- (a) Datura
- (b) Mustard
- (c) Gulmohur
- (d) Tomato
- Which one of the following statements is correct 88.

[NCERT; CBSE PMT (Pre.) 2011]

- (a) Flower of tulip is a modified shoot
- (b) In tomato, fruit is a capsule
- (c) Seeds of orchids have oil-rich endosperms
- (d) Placentation in primose is basal
- Which of the following plants has the floral characters like zygomorphic flower, vexillary aestivation, diadelphous androecium and marginal placentation [Kerala PMT 2011]
 - (a) Pisum
- (b) Belladonna
- (c) Brinjal
- (d) Asparagus
- (e) Aloe
- Flowers are unisexual in 90. (a) Cucumber
- (b) China rose
- Onion
- (d) Pea
- Thalamus of hypogynous ovary is 91.
 - [Odisha JEE 2011]

[AIPMT 2015]

- (a) Convex
- (b) Concave
- (c) Flat with partly cup shaped
- (d) None of these
- The type of placentation in which ovary is syncarpous 92. [CPMT 2010] unilocular and ovules on sutures is called
 - (a) Marginal placentation
- (b) Apical placentation
- (c) Parietal placentation
- (d) Superficial placentation
- The ovary is half inferior in flowers of 93.

[NCERT; CBSE PMT (Pre.) 2010, 11]

- (a) Guava
- (b) Peach/Plum
- (c) Cucumber
- (d) Cotton
- The gynoecium consists of many free pistils in flowers of 94.

[CBSE PMT (Pre.) 2012]

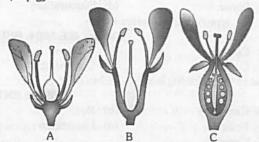

- (a) Aloe
- (b) Tomato
- (c) Papaver
- (d) Michelia
- The condition in which stamens are fused by anthers only, whereas the filaments remain free, is termed as

[Odisha JEE 2012]

- (a) Adelphous
- (b) Syngenesious
- (c) Synandrous
- (d) Polyandrous
- Among bitter gourd, mustard, brinjal, pumpkin, chinarose, 96. lupin, cucumber, sunnhemp, gram, guava, bean, chilli, plum, petunia, tomato, rose, withania, potato, onion, aloe and tulip how many plants have hypogynous flower [NEET 2013]
 - (a) Eighteen
- (b) Six
- (c) Ten
- (d) Fifteen
- Among flowers of Calotropis, tulip, Sesbania, Asparagus, Colchicine, Sweet pea, Petunia, Indigofera, Mustard, Soyabean, Tobacco and groundnut how many plants have [NEET (Karnataka) 2013] corolla with valvate aestivation
 - (a) Six

- (b) Seven
- (c) Eight
- (d) Five

- 98. Match the following figures with I, II and III
 - (I) Hypogynous flower
- (II) Perigynous flower
- (III) Epigynous flower

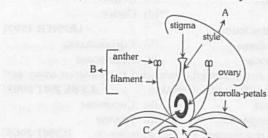

[NCERT]

- (a) A-III, B-I, C-II
- (b) A−III, B−II, C−I
- (c) A-I, B-III, C-II
- (d) A-I, B-II, C-III
- Match the Column I with Column II and Column III 99.

Column I	Column II	Column III
A. Marginal	I. ()	Sunflower, Marigold
B. Axile	II. (3)	2. Dianthus, Primrose
C. Parietal	III. (3)	3. Mustard, Argemone
D. Free Central	IV.	4. China rose, Tomato, Lemon
E. Basal	v.	5. Pea

[NCERT; Kerala PMT 2010, 11; NEET (Phase-II) 2016]

- (a) A-V, 1; B-III, 2; C-II, 4; D-I, 5; E-IV, 3
- (b) A-V, 1; B-II, 4; C-I, 2; D-III, 3; E-IV, 5

- (d) A-V, 5; B-II, 4; C-I, 3; D-III, 2; E-IV, 1
- 100. See figure of a typical flower. In which one of the options all the four parts A, B, C and D are correctly identified [NCERT]

	A	В	C	D
(a)	Gynoecium	Stamen	Ovule	Thalamus
(b)	Microsporophyll	Stamen	Ovule	Thalamus
(c)	Gynoecium	Stamen	Seed	Thalamus
(d)	Gynoecium	Megasporophyll	Ovule	Thalamus

101. When the margins of sepals or petals overlap one another without any particular direction, the condition is termed as

[CBSE PMT 2014]

- (a) Twisted
- (b) Valvate
- (c) Vexillary
- (d) Imbricate
- 102. The standard petal of a papilionaceous corolla is also called

[NEET (Phase-I) 2016]

- (a) Carina
- (b) Pappus
- (c) Vexillum
- (d) Corona
- 103. Proximal end of the filament of stamen is attached to the

[NEET (Phase-I) 2016]

- (a) Anther
- (b) Connective
- (c) Placenta
- (d) Thalamus or petal
- 104. The term 'polyadelphous' is related to

[NEET (Phase-II) 2016]

- (a) Calux
- (b) Gynoecium
- (c) Androecium
- (d) Corolla
- 105. Radial symmetry is found in the flowers of

[NEET (Phase-II) 2016]

- (a) Cassia
- (b) Brassica
- (c) Trifolium
- (d) Pisum
- Seeds and Fruits
- Seeds of the orchids are
 - (a) Large and heavy
- (b) Light and dry
- (c) Minute and sticky
- (d) None of these
- 2. Single flower with multiple ovaries is called

[Odisha JEE 2008]

- (a) Composite fruit
- (b) Simple fruit
- (c) Aggregate fruit
- (d) None of these
- 3. The megasporangium of the angiosperms on maturation gives rise to
 - (a) A fruit
- (b) Seed
- (c) An embryo
- (d) Cotyledons
- 4. After fertilization, the seed coats of seed develop from

IRPMT 20021

- (a) Integuments
- (b) Embryo sac
- (c) Chalaza
- (d) Ovule
- Cereals during germination derive their food from 5.

[Odisha JEE 2008]

- (a) Starch
- (b) Soil
- (c) Aleurone grains
- (d) Embryo
- 6 Karyopsis is

- [VITEEE 2008]
- (a) One seeded fruit
- (b) Two seeded fruit
- (c) Three seeded fruit
- (d) Four seeded fruit
- Cotyledons and testa respectively are edible parts in 7.

[CBSE PMT 2009]

- (a) Groundnut and pomegranate
- (b) Walnut and tamarind
- (c) French bean and cocount
- (d) Cashew nut and litchi
- Plants with inferior ovary usually bear [AIIMS 2012]
 - (a) Pseudocarps
- (b) Berries
- (c) Aggregate fruits
- (d) Seedless fruits

9.	The plant whose seeds are known to have longest viability period is [AIIMS 1993]	21.	A fleshy-fruit with leathery exocarp is called [Odisha JEE 2004]
	(a) Nelumbo nucifera (lotus) (b) Triticum vulgare (wheat)		(a) Drupe (b) Berry
	(c) Zizyphus jujuba (ber) (d) Carica papaya (papaya)		(c) Pome (d) Hesperidium
10	Which one of the following is a non-endospermic seed	22.	type of fruit is present in rice
10.	[MHCET 2015]		[Odisha JEE 2004; BHU 2008] (a) Cypsela (b) Capsule
	(a) Sunflower (b) Coconut		(a) Cypsela (b) Capsule (c) Caryopsis (d) Cremocarp
		23.	One of the following is a dry indehiscent fruit
	(c) Croame men		[CBSE PMT 2004]
11.	"Embryo are not differentiated into different tissues at the time of fruit ripening". Select option related to this statement		(a) Caryopsis (b) Pod
	[GUJCET 2014]		(c) Follicle (d) Lomentum
			(e) Capsule The ground nut seeds are [MHCET 2000]
	(a) Exogenous dormancy, physiological dormancy	24.	The ground nut seeds are (a) Geocarpic (b) Photocarpic
	(b) Endogenous dormancy, morphological dormancy		(c) Amphicarpic (d) Hydrocarpic
	(c) Exogenous dormancy, morphological dormancy	25.	The Party 00041
	(d) Endogenous dormancy, mechanical dormancy		(a) Inflorescence (b) Plant
12.	Seed develop from [CBSE PMT 1993; MP PMT 2010, 12]		(c) Fruit (d) Insect
	(a) Ovules (b) Ovaries	26.	
	(c) Anthers (d) Pistils		[CBSE PMT 2009]
13.	In non-endospermic seeds, food is stored in [CPMT 1996]		(a) Hesperidium (b) Sorosis (c) Suconus (d) Caryopsis
500	(a) Seed coat (b) Endosperm	07	THE PART AND COOPE
	(c) Cotyledons (d) Ovule	27.	(a) Seed (b) Embryo
14.	Vivipary means [RPMT 1995]		(c) Ovule (d) Fruit
1.4.	(a) Fruits are not formed	28.	The fruit in Datura is [MHCET 2000]
	(b) Germination of seed on mother plant		(a) Loculicidal capsule (b) Septifragal capsule
	(c) Formation of fruits directly by embryo		(c) Septicidal capsule (d) Porous capsule
	(d) Production of fruitless plant	29.	
15.	In which of the following the seed germinates and still		(a) Endosperm (b) Cotyledon (c) Embryo (d) Kernel
13.	attached with the main plant [AFMC 1995]	30.	(5)
	(a) Mango (b) Rhizophora	30.	seed coat, is called [BVP 2004; AFMC 2004
	(c) Neem (d) Coconut		(a) Stratification (b) Scarification
16.	Edible part of mango is		(c) Vernalization (d) Photoperiodism
10.	[NCERT; BVP 2002; CBSE PMT 2004; AFMC 2010]	31.	
	(a) Epicarp (b) Mesocarp		caruncle is [CBSE PMT 2009
	(c) Endocarp (d) Receptacle		Or Which one of the following is an endospermic seed
17.	Placenta and pericarp are both edible portions in		[Kerala CET 2002
	[BCECE 2005; KCET 2007; CBSE PMT 2014]		Or Or Annual Control of the Control
	(a) Tomato (b) Potato		In which of the following plants, cotyledons form the first
	(c) Apple (d) Banana		pair of leaves
18.	In caryopsis type of fruit [MHCET 2004; J & K CET 2008]		(a) Cotton (b) Coffee (c) Lily (d) Castor
	(a) Seed is absent	32.	THE TOTAL TO
	(b) Three layers of pericarp are distinct		(a) Cruciferae (b) Cucurbitaceae
	(c) Seed coat and pericarp are fused		(c) Liliaceae (d) Solanaceae
	(d) Autochory occurs	33.	
19.	Aggregate fruit develops from		has seeds with succulent testa in [CBSE PMT 2008
	[MHCET 2003; Odisha JEE 2011; CBSE PMT 2014]		(a) Guava (b) Cucumber (c) Pomegranate (d) Orange
	(a) Multicarpellary, apocarpous ovary	34.	CONT CONT
	(b) Multicarpellary ovary	34.	(a) H_2O and O_2
	(c) Multicarpellary, syncarpous ovary		(b) O ₂ and light
	(d) Monocarpellary ovary		(c) H ₂ O and high temperature
20.	Which of the following is a wheat fruit		(d) Scarification and vernalisation
20.	[BHU 2004; AFMC 2009]	35.	
	(a) Achene (b) Cypsella		(a) Mesocarp (b) Endocarp
	(c) Carvonsis (d) Endosperm		(c) Aril (d) Placental hairs

36. The fruit developed from the single ovary is said to be

[J & K CET 2005; KCET 2012]

- (a) Composite type
- (b) Simple type
- (c) Aggregate type
- (d) None of these
- 37. The fleshy fruits with hard and stony endocarp are called

[J & K CET 2005; KCET 2009]

- (a) Drupe
- (b) Berry
- (c) Pepo
- (d) Pome
- 38. The edible dry fruit 'chilgoza' is

[BHU 2005]

- (a) Fruit of Cycas
- (b) Fruit of Pinus gerardiana
- (c) Seed of Cycas
- (d) Seed of Pinus gerardiana
- 39. Edible part in 'sorosis' a composite fruit is

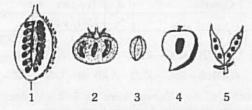

[BHU 2005]

- (a) Cotyledons
- (b) Endosperm
- (c) Perianth and peduncle
- (d) Fleshy thalamus
- 40. Fruit of grape vine is
- [Odisha JEE 2012]

- (a) Siliqua
- (b) Lomentum
- (c) Berry
- (d) Drupe
- The given figure represents anacardium (cashewnut). Which is the correct statement [Manipal 2005]
 - (a) The upper part is a false fruit
 - (b) The upper part is a true fruit
 - (c) The lower part is a seed
 - (d) There is no fruit at all
- 42. Edible part of Apple is

[Odisha JEE 2005; AMU (Med.) 2006; J & K CET 2012]

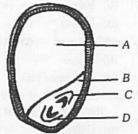

- (a) Mesocarp
- (b) Calyx
- (c) Thalamus
- (d) Pericarp
- 43. The hardest part of drupe is
- [Manipal 2005]
- (a) Mesocarp
- (b) Endocarp
- (c) Pericarp
- (d) Epicarp
- 44. Which of the following correctly represents the type of fruits given [Kerala PMT 2000]

- (a) 1. Berry; 2. Caryopsis; 3. Drupe; 4. Sorosis;
 - 5. Aggregate
- (b) 2. Berry; 3. Caryopsis; 4. Drupe; 1. Sorosis;
 - 5. Aggregate
- (c) 2. Berry; 3. Caryopsis; 4. Drupe; 5. Legume;
 - 1. Aggregate
- (d) 1. Beccate; 3. Caryopsis; 4. Drupe; 1. Sorosis;
 - 5. Composite
- (e) 2. Berry; 3. Caryopsis; 4. Drupe; 1. Sorosis;
 - 5. Legume

45. The diagram represents the L. S of monocot seed. Choose the correct combination of labelling

[Kerala PMT 2006; KCET 2009]

- (a) (A) Alerone layer (B) Scutellum (C) Coleoptile (D) Coleorhiza
- (b) (A) Seed coat (B) Scutellum (C) Coleoptile (D) Coleorhiza
- (c) (A) Epithelium (B) Scutellum (C) Coleoptile (D) Coleorhiza
- (d) (A) Endosperm (B) Scutellum (C) Coleoptile (D) Coleorhiza
- (e) (A) Endosperm (B) Scutellum (C) Plumule (D) Radicle
- 46. Match the items in column I with column II and choose the correct answer

	Column I	Column II			
A. Apple		1.	Outer portion of receptacle		
B.	Coconut	2.	Fleshly thalamus		
C.	Jack fruit	3.	Thalamus & pericarp		
D.	Guava	4.	Endosperm		
E.	Pineapple		Bract, perianth & seeds		

[Kerala PMT 2006]

- (a) A-2, B-3, C-4, D-5, E-1
- (b) A-5, B-3, C-1, D-4, E-2
- (c) A-2, B-3, C-1, D-5, E-4
- (d) A-2, B-4, C-5, D-3, E-1
- (e) A-5, B-4, C-3, D-2, E-1
- 47. How many plants in the list given below have composite fruits that develop from an inflorescence. Walnut, poppy, radish, fig, pineapple, apple, tomato, mulberry

[NCERT: CBSE PMT (Pre.) 2012]

- (a) Four
- (b) Five
- (c) Two
- (d) Three
- A fruit developed from a condensed inflorescence is [AIIMS 2010]
 - (a) Simple fruit
- (b) Aggregate fruit
- (c) Composite fruit
- (d) Etaerio
- 49. Pineapple (ananas) fruit develops from

[CBSE PMT 2006; DUMET 2009]

- (a) A cluster of compactly borne flowers on a common axis
- (b) A multilocular monocarpellary flower
- (c) A unilocular polycarpellary flower
- (d) A multipistillate syncarpous flower
- 50. In which of following fruits is the edible part the aril

[CBSE PMT 1999, 2005, 06; Wardha 2005; AFMC 2009]

- (a) Orange
- (b) Litchi
- (c) Custard apple
- (d) Pomegranate

An enzyme that can stimulate germination of barley seeds is

[CBSE PMT 2006]

[DPMT 2006]

- (a) Protease
- (b) Invertase
- (c) α-amylase
- (d) Lipase
- 52. Hesperidium of orange is a modification of
 - (b) Drupe
 - (a) Berry (c) Pome
- (d) Aggregate fruit
- 53. In a cereal grain the single cotyledon of embryo is [NCERT; CBSE PMT 2006] represented by
 - (a) Prophyll
- (b) Coleoptile
- (c) Coleorhiza
- (d) Scutellum
- Match Column I with Column II and choose the correct

	Column – I	Column – II		
A.	Coleorhiza	1.	Grapes	
B.	Food storing tissue	2.	Mango	
C.	Parthenocarpic fruit	3.	Maize	
D.	Single seeded fruit developing from monocarpellary superior ovary	4.	Radicle	
E.	Membranous seed coat	5.	Endosperm	

[NCERT; Kerala PMT 2007]

- (a) A-3, B-1, C-4, D-2, E-5
- (b) A-4, B-2, C-5, D-1, E-3
- (c) A-5,B-1,C-3,D-4,E-2
- (d) A-1, B-3, C-2, D-5, E-4
- (e) A-4,B-5,C-1,D-2,E-3
- Dry indehiscent single-seeded fruit formed from bicarpellary syncarpous inferior ovary is [CBSE PMT 2008]
 - (a) Berry
- (b) Cremocarp
- (c) Caryopsis
- (d) Cypsela
- The fleshy receptacle of syconus of fig encloses a number of 56.

[CBSE PMT 2008]

- (a) Berries
- (b) Mericarps
- (c) Achenes
- (d) Samaras
- In which plant the fruit is a drupe, seed coat is thin, embryo 57. is inconspicuous and endosperm is edible INCERT:

DUMET 2009; CPMT 2010; NEET 2017]

- (a) Groundnut
- (b) Wheat
- (c) Apple
- (d) Coconut
- 58. Which one of the following is a true nut

[BHU 2008]

- (a) Walnut
- (b) Groundnut (d) Coconut
- (c) Cashewnut 59. In drupe of coconut the mesocarp is

INCERT:

AMU (Med.) 2009, 12]

- (a) Fleshy
- (b) Fibrous
- (c) Stony
- (d) Watery
- 60. An example of false fruit is

- [CPMT 2009; AFMC 2010]
- (a) Apple
- (c) Grapes
- (b) Banana (d) Mango

- Bracts, perianth and seeds are edible parts of [MP PMT 2010] 61.
 - (a) Cocos nucifera
 - (b) Artocarpus heterophyllus
 - (c) Magnifera indica
 - (d) Argemone mexicana
- 62. Which one of the following statements is correct

[NCERT; CBSE PMT 2014]

- (a) A proteinaceous aleurone layer is present in maize grain
- (b) A sterile pistil is called a staminode
- (c) The seed in grasses is not endospermic
- (d) Mango is a parthenocarpic fruit
- Non endospermic seeds are found in [Odisha JEE 2010]
 - (a) Wheat
- (b) Castor
- (c) Barley
- (d) Bean
- The scutellum observed in a grain of wheat or maize is comparable to which part of the seed in other monocotyledons [CBSE PMT (Pre.) 2010]
 - (a) Plumule
- (b) Cotyledon
- (c) Endosperm
- (d) Aleurone layer
- A drupe develops in 65.
- [CBSE PMT (Pre.) 2011] (b) Mango
- (a) Tomato (c) Wheat
- (d) Pea
- Read the following statements A and B
 - (A) Many organs of aquatic plants float in water
 - (B) Large air gaps are present in the collenchyma tissues of lotus leaf

Select the correct answer

[KCET 2011]

- (a) Statement A is correct and B is wrong
- (b) Statement B is correct and A is wrong
- (c) Statements A and B both are correct
- (d) Statements A and B both are wrong
- Match the types of fruits listed in Column I with the examples listed in Column II. Choose the answer which gives the correct combination of the two columns

	Column I	Column II		
A.	Capsule	1.	Paddy	
B.	Berry	2.	Mango	
C.	Drupe	3.	Sunflower	
D.	Cypsela	4.	Tomato	
		5.	Lady's finger	

IKCET 20111

- (a) A-5, B-4, C-2, D-3 (b) A-5, B-3, C-1, D-2
- (c) A-4, B-5, C-2, D-3 (d) A-1, B-2, C-3, D-5
- In which of the following types the fruit is multilocular and split open longitudinally along dorsal sutures

[Odisha JEE 2010]

INEET 20131

- (a) Capsular
- (b) Loculicidal
- (c) Septicidal
- (d) Septifragal
- Seed coat is not thin, membranous in

 - (a) Gram
- (b) Maize
- (c) Coconut
- (d) Groundnut
- Albuminous seeds store their reserve food mainly in 70. [NEET (Karnataka) 2013]

(a) Endosperm

- (b) Cotyledons
- (c) Hypocotyl
- (d) Perisperm

Figure - I - Mango, Figure - II - Coconut are shown in the following diagram. Identify the parts of the fruit A, B, C and D are respectively

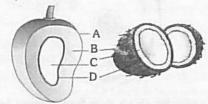

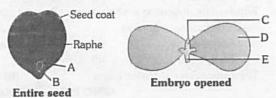

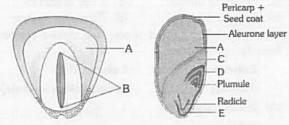

Figure - I

Figure - II

- (a) Epicarp, Mesocarp, Embryo, Endocarp
- (b) Epicarp, Mesocarp, Ovary, Endocarp
- (c) Epicarp, Mesocarp, Ovule, Endocarp
- (d) Epicarp, Mesocarp, Seed, Endocarp
- The following diagram is the typical structure 72. dicotyledonous seeds. In which one of the options all the five parts A to E are correctly identified [NCERT]

- (a) A Hilum, B Micropyle, C Plumule, D Radicle, E - Cotyledon
- (b) A Micropyle, B Hilum, C Plumule, D Cotyledon, E - Radicle
- (c) A Hilum, B Micropyle, C Plumule, D Cotyledon, E - Radicle
- (d) A Hilum, B Micropyle, C Radicle, D Cotyledon, E - Plumule
- The following diagram is the typical structure of 73. monocotyledonous seeds. Identify all the five parts A, B, C, D and E [NCERT]

- (a) A Embryo, B Endosperm, C Scutellum, D -Coleorrhiza, E - Coleoptile
- (b) A Endosperm, B Embryo, C Scutellum, D -Coleoptile, E - Coleorrhiza
- (c) A Embryo, B Endosperm, C Scutellum, D -Coleoptile, E - Coleorrhiza
- (d) A Endosperm, B Embryo, C Scutellum, D -Coleorrhiza, E - Coleoptile
- 74. Non-albuminous seed is produced in [CBSE PMT 2014]
 - (a) Wheat
- (b) Pea
- (c) Maize
- (d) Castor

Dispersal of fruits and seeds

- 1. The most common method for dispersal of fruits and seeds in legumes is
 - (a) Autochory
- (b) Anemichory
- (c) Zoochory
- (d) Hydrochory
- 2. Bright coloured fleshy fruits are dispersed by

[Odisha JEE 2008]

Or

Seeds of Mulberry are dispersed by

- (a) Insect
- (b) Air
- (c) Water
- (d) Bird
- Parachute mechanism of seed dispersal occurs in 3.

[MHCET 2003]

Or

Seeds are dispersed by wind in

- (a) Xanthium
- (b) Calotropis
- (c) Mango
- (d) Apple
- Hairy styles are present in 4.
 - (a) Ranunculus
- (b) Clematis
- (c) Mucuna
- (d) Polygonum
- Dispersal by explosive fruits is shown by 5.
 - (a) Barleria
- (b) Impatiens and Rueillia
- (c) Acanthus and Phlox
- (d) All of these
- 6. In Ruellia and Justicia dispersal of seeds takes place by (a) Jaculator mechanism
 - (b) Censer mechanism
 - (c) Winged seeds
- (d) Parachute mechanism
- Seed dispersal by parachute type mechanism is found in

[CPMT 1998; MP PMT 2013]

- (a) Pea of Fabaceae
- (b) Mustard of Brassicaceae
- (c) Cotton of Malvaceae
- (d) Taraxacum of Asteraceae / compositeae
- 8. The fruits and seeds which are either sticky, have different types of outgrowths are capable of undergoing
 - (a) Forced zoochory
- (b) Compensated zoochory
- (c) Hydrochory
- (d) Anemochory
- The dispersal of cotton and madar seeds takes place by 9. wind because of
 - (a) Wings
- (b) Hairs
- (c) Pappus
- (d) Bracts
- 10. In which of the following plants dispersal of fruits takes place by parachute mechanism
 - (a) Terminalia
- (b) Tagetes
- (c) Moringa
- (d) Acer
- The fruits of Xanthium are dispersed by animals because
 - (a) These are having sticky substance
 - (b) These are edible
 - (c) These are provided with hooks
 - (d) These are light in weight
- An example of fruit which is dispersed by bird is 12.
 - (a) Calotropis
- (b) Mirabillis
- (c) Argemone
- (d) Bignonia

356 Morphology of Flowering Plants In Rafflesia, seeds are dispersed by (a) Wind (b) Elephant (d) Flies (c) Mites An example of compensated Zoochory is (a) Mango (b) Apricot (d) All of these (c) Tomato 15. In drumstick the seeds are dispersed by [DPMT 2006] (b) Animals (a) Water (d) Explosive mechanism (c) Wind 16. Aril helps in (a) Buoyancy to seeds of Nymphaea to float in water (b) Dispersal in litchi by animals (c) None as it is an edible part (d) Both (a) and (b) 17. Winged seeds occur in (b) Moringa (a) Chorea (c) Cotton (d) Calotropis Dispersal of fruits in Opium (poppy) occurs through shaking 18. [CPMT 2000] by wind by (a) Explosive mechanism (b) Parachute mechanism (c) Censer mechanism (d) Jacular mechanism Some plants have a habit of harbouring ants to save the 19. plants from damage by other animals which is known as (b) Myrmecophily (a) Entomophily (d) Hydrophily (c) Anemophily (e) Zoophily **Taxonomy of Angiospermic plants** The correct floral formula of Liliaceae is (c) $\uparrow \ Q^T \ P_{3+3} \ A_{3+3} \ G_{(3)}$ (d) $\uparrow \ Q^T \ P_{3+3} \ A_{3+3} \ G_{(6)}$ 2. (a) Fabaceae and Poaceae (b) Liliaceae and Solanaceae (c) Malvaceae and Brassicaceae (d) Liliaceae and Poaceae 3. Bentham and Hooker's system (a) Thalamiflorae, Parietales (b) Inferae, Asterales (c) Calyciflorae, Rosales

[Kerala PMT 2006] [RPMT 1992; APMEE 1992; CPMT 1993, 97] (a) \oplus $\slashed{Q}^{"}$ P_{3+3} A_6 $G_{(3)}$ (b) $Br \oplus$ $\slashed{Q}^{"}$ P_{3+3} A_{3+3} $G_{(3)}$ The two families dominate in having maximum useful plants [Pb. PMT 1993; CBSE PMT 1997] The systematic position of Cucurbitaceae according to (d) Calyciflorae, Passiflorales [RPMT 1995] Touch me not belongs to (a) Liliaceae (b) Solanaceae (d) Malvaceae (c) Mimosoideae Which of the following families is characterised by the 5. presence of perianth (a) Malvaceae (b) Liliaceae (c) Cruciferae (d) Solanaceae

Plants having the above given floral diagram are

[AIIMS 2012]

- (a) Leguminous
- (b) Dicots

6.

- (c) Medicinal and perennial
- (d) Having pinnately compound leaves
- The host for Cercospora personata belongs to this family of 7. angiosperms
 - (a) Gramineae
- (b) Leguminosae
- (c) Malvaceae
- (d) Asclepiadaceae
- 8. Which of the following is phylogenetically most advanced of [Odisha JEE 2005] the dicotyledonous families
 - (a) Acanthaceae
- (b) Scrophulariaceae
- (c) Compositae
- (d) Umbelliferae
- The androecium of Malvaceae is **IRPMT 1996:** AFMC 1994; AMU (Med.) 1997]
 - (a) Didynamous
- (b) Tetradynamous
- (c) Diadelphous
- (d) Monadelphous
- 10. Rutaceae differs from Malvaceae in having
- [BHU 1997]

- (a) Simple leaves
- (b) Polypetalous corolla
- (c) Syncarpous, superior ovary
- (d) Obdiplostemonous stamens
- Which statement is wrong for compositae **ICPMT 19981** 11.
 - (a) 5-lobed stamens
- (b) Syngenesious stamens
- (c) Basal ovule
- (d) Ligulate ray florets
- 12. Red Gram is
 - (a) Phaseolus aureus
- (b) Cicer arietinum
- (c) Cajanus cajan
- (d) Phaseolus mungo
- Match the following and choose the correct combination 13. from the options given

Column I Column II (Family) (Androecium formula) (A) Brassicaceae/ A_{3+3} cruciferae (B) Fabaceae A(5) (C) Solanaceae $A_{(9)+1}$ (D) Liliaceae A2+4

[CPMT 1997; AIIMS 2001; Kerala PMT 2012]

- (a) A-4, B-3, C-2, D-1
- (b) A-1, B-2, C-3, D-4
- (c) A-2, B-3; C-4, D-1
- (d) A-3, B-4, C-1, D-2
- (e) A-4, B-3, C-1, D-2

- 14. Millets belong to

[APMEE 1994]

- (a) Fabaceae
- (b) Poaceae
- (c) Liliaceae
- (d) Asteraceae

- Commissural stigma (Along carpellary cohesion plane) 15. occurs in family [APMEE 1994]
 - (a) Solanaceae
- (b) Liliaceae
- (c) Cruciferae
- (d) Fabaceae
- Carthamus tinctorium belongs to family 16.
 - (a) Asteraceae
- (b) Solanaceae

[CBSE PMT 1991]

- (c) Malvaceae
- (d) Fabaceae
- Botanical name of Cauliflower is
 - (a) Brassica oleracea var. capitata
 - (b) Brassica campesteris
 - (c) Brassica oleracea var. botrytis
 - (d) Brassica oleracea var. gemmifera
- Plants are always herbs in
 - (a) Fabaceae
- (b) Solanaceae
- (c) Brassicaceae
- (d) None of these
- See the following figures and identify the given below species 19. belong to which of the following families respectively [NCERT]

Pisum Sativum (pea)

Solanum nigrum (mokol) Allium cepa (Onion)

- (a) Solanaceae, Fabaceae, Liliaceae
- (b) Compositae, Malvaceae, Liliaceae
- (c) Fabaceae, Solanaceae, Liliaceae
- (d) Liliaceae, Compositae, Malvaceae
- A family delimited by type of inflorescence is 20.

[CBSE PMT 1990]

Or

A family belongs to inferae and gamopetalae

- (a) Fabaceae
- (b) Asteraceae
- (c) Solanaceae
- (d) Liliaceae
- Axile placentation occurs in
 - (a) Asteraceae and Fabaceae
 - (b) Brassicaeae and Solanaceae
 - (c) Solanaceae and Liliaceae
 - (d) All of these
- A diagnostic trait for identification of fabaceous flower is 22.

[NCERT]

- (a) Tetradynamous androecium
- (b) Inferior ovary
- Cruciform corolla
- (d) Vexillary aestivation
- Which of the following is not correctly paired 23.

[AMU (Med.) 2010]

- (a) Fabaceae: Legume family
- (b) Solanaceae: Potato family
- (c) Liliaceae : Sunflower family
- (d) Brassicaceae: Mustard family

- Botanical name of Finger Millet is
 - (a) Sorghum vulgare
- (b) Eleusine coracana
- (c) Amaranthus viridis
- (d) Pennisetum typhoides
- Flower of Fabaceae is 25.
- [JIPMER 2002]
- (a) Complete, zygomorphic, pentamerous
- (b) Complete, actinomorphic, trimerous
- (c) Incomplete, zygomorphic, trimerous
- (d) Incomplete, actinomorphic, pentamerous
- Most important character of Brassica campesteris is 26.

[AFMC 1992; APMEE 1995; RPMT 2002]

- (a) False septum
- (b) Parietal placentation
- (c) Ebracteate
- (d) Imbricate aestivation
- In fabaceae, one of the following immediately encloses the 27. [APMEE 2002] essential organs
 - (a) Anterior petals
- (b) Posterior petal
- (c) Lateral petals
- (d) Sepals
- Given diagram shows the cohesion of stamens. It is the 28. characteristic of pulse family. Identify the type of cohesion

- (a) Synandrous
- (b) Polyadelhpous
- (c) Diadelphous
- (d) Monoadelphous
- Four sepals arranged in two whorls is characteristic of family 29. [Manipal 2001; BHU 2002]
 - (a) Solanaceae
- (b) Fabaceae
- (c) Brassicaceae
- (d) Liliaceae
- Andromonoecious guggal (Commiphora wightii) plants population are those that [MP PMT 2013]
 - (a) Produce more male flower bearing plants and a few female flower bearing plants in a population
 - (b) Produce more female flower bearing plants and a few male flower bearing plants in a population
 - (c) Produce male flowers bearing plants and female flowers bearing plants in equal number in a population
 - (d) Produce both male and bisexual flower bearing individual in a population Largest family of flowering plants is

[Tamil Nadu 2001]

[DPMT 2001]

[APMEE 1996]

Compositae is also known as

(d) Thalamiflora

- (a) Fabaceae (c) Poaceae
 - (d) Asteraceae
- 32. Family Fabaceae belongs to series (a) Inferae
 - (b) Thalamiflorae
 - (c) Calyciflorae
- (d) Disciflorae
- Familiar examples of family Liliaceae are

[KCET 1995: Pb. PMT 1999; RPMT 1999]

- (a) Allium cepa, Aloe vera and Tamarindus indica
- (b) Saraca indica, Allium cepa and Aloe vera
- (c) Allium sativum, Allium cepa and Aloe vera
- (d) Tamarindus indica, Allium cepa and Allium sativum

[NEET (Phase-I) 2016]

- (a) Liliaceae
- (b) Solanaceae
- (c) Fabaceae
- (d) Poaceae

Exemplar Questions

- Rearrange the following zones as seen in the root in vertical section and choose the correct option
 - A. Root hair zone
- B. Zone of meristems
- Rootcap zone
- D. Zone of maturation
- E. Zone of elongation

Options:

INCERTI

- (a) C, B, E, A, D
- (b) A, B, C, D, E
- (c) D, E, A, C, B
- (d) E, D, C, B, A
- In an inflorescence where flowers are borne laterally in an 2. acropetal succession, the position of the youngest floral bud shall be [NCERT]
 - (a) Proximal
- (b) Distal
- (c) Intercalary
- (d) Any where
- The mature seeds of plants such as gram and peas, possess' no endosperm, because [NCERT]
 - (a) These plants are not angiosperms
 - (b) There is no double fertilization in them
 - (c) Endosperm is not formed in them
 - (d) Endosperm gets used up by the developing embryo during seed development

Match the followings and choose correct option

Group A

Group B

- A. Aleurone layer
- i. Without fertilization
- B. Parthenocarpic fruit
- ii. Nutrition
- C. Ovule
- iii. Double fertilization
- D. Endosperm
- iv. Seed

Option:

[NCERT]

- (a) A-i, B-ii, C-iii, D-iv
- (b) A-ii, B-i, C-iv, D-iii
- (c) A-iv, B-ii, C-i, D-iii
- (d) A-ii, B-iv, C-i, D-iii
- Venation is a term used to describe the pattern of arrangement of [NCERT]
 - (a) Floral organs
 - (b) Flower in infloresence
 - (c) Veins and veinlets in a lamina
 - (d) All of them
- **6.** Endosperm, a product of double fertilization in angiosperms is absent in the seeds of [NCERT]
 - (a) Gram
- (b) Orchids
- (c) Maize
- (d) Castor
- 7. Which of the following plants is used to extract the blue dye
 - [NCERT]

- (a) Trifolium
- (b) Indigofera
- (c) Lupin
- (d) Cassia
- 8. The placenta is attached to the developing seed near the
 - [NCERT]

- (a) Testa
- (b) Hilum
- (c) Micropyle
- (d) Chalaza

Critical Thinking

- A plant called plantless root is
 - (a) Arceuthobium
- (b) Podostemon

Objective Questions

- (c) Rafflesia and Sapria
- (d) All of these
- 2. Study the following lists

	List-I		List-II
(A)	Spongy aril	(I)	Jussiaea
(B)	Multiple epidermis	(II)	Pistia
(C)	Respiratory roots	(III)	Nerium
(D)	Root pockets	(IV)	Sagittaria
	And the first	(V)	Numphaea

The correct match is

[EAMCET 2009]

na i	A	В	С	D
(a)		III	II	V
(b)		I	IV	III
(c)		II	III	1
(4)		III	1	II

The floral formula of the given floral diagram is

[Kerala PMT 2007]

- (a) $Br K_{Pappus} C_{(5)} A_0 G_{\overline{(2)}}$
- (b) $BrQ^{7}K_{Pappus}C_{(5)}A_{(5)}G(1)$
- (c) $Br \not Q : K_{5(Pappus)} \overline{C_{(5)} A_{(5)}}, G_{\overline{(2)}}$
- (d) $Br \not Q . K_{Pappus} \overline{C_{(5)} A_{(5)}}, G_{(2)}$
- (e) $Br Q^{7}K_{Pappus} \overline{C_5 A_5} G_{(2)}$

Study the following lists

	List-I		List-II				
(A)	Coleorhiza	(I)	Development of sporophyte directly from gametophyte without intervention of gametes				
(B)	Apogamy	(II)	Development of gametophyte directly from sporophyte without the involvement of reduction division				
(C)	Indusium	(III)	An unbranched columnar stem with a crown of leaves				
(D)	Caudex	(IV)	Protective covering of radicle				
		(V)	Protective structure of a sorus				

 The correct match is
 [EAMCET 2009]

 A
 B
 C
 D

 (a) V
 II
 IV
 I

 (b) IV
 I
 V
 III

 (c) III
 V
 II
 IV

5. Fruit of custard apple is

(d) II

- [AFMC 2004]
- (a) Etaerio of berries

III

- (b) Etaerio of follicles
- (c) Etaerios of achenes
- (d) Ethaerio of drups
- 6. Which one of the following organisms is correctly matched with its three characteristics [NCERT;
 - CBSE PMT (Mains) 2012]
 - (a) Pea : C_3 pathway, Endospermic seed, Vexillary aestivation
 - (b) Tomato: Twisted aestivation, Axile placentation, Berry
 - (c) Onion : Bulb, Imbricate aestivation, Axile placentation
 - (d) Maize : C_3 pathway, Closed vascular bundles, Scutellum
- 7. Cladodes are common among

[AMU (Med.) 1999; J & K CET 2008]

- (a) Liliaceae/Asparagus and Ruscus
- (b) Opuntia and Casurina
- (c) Cactus
- (d) Euphorbia

UNIVERSAL BOOK DEPOT 1960

- 8. Identify the incorrect statements from the following
 - P. Cymose inflorescence is found in Hibiscus sp
 - Q. Hypanthodium is found in Ficus benghalensis
 - R. Synandrous stamen is found in Calotropis
 - S. Hesperidium type of fruit is Mango

[WB JEE 2012]

- (a) R, S
- (b) P, Q
- (c) Q, R
- (d) P.S
- In hypogeal germination due to elongation ofplumule comes out of the ground [Odisha JEE 2010]

Or

The portion of embryonal axis above cotyledon is called as

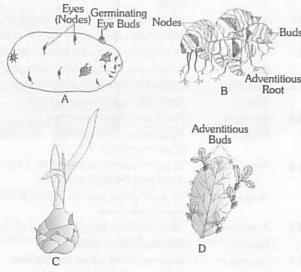

[J & K CET 2012]

- (a) Hypocotyl
- (b) Epicotyl
- (c) Cotyledons
- (d) Both (a) and (b)
- 10. Bisexual flowers which never open, demonstrate

[MP PMT 2004]

- (a) Cleistogamy
- (b) Allogamy
- (c) Autogamy
- (d) None of these
- Study the diagrams given below and select the right options out of (a - d); in which all the 4 items A, B, C and D are correctly identified

 INCERTI

	A	В	C	D
(a)	Offset	Sucker	Stolon	Leaf buds
(b)	Offset	Sucker	Stolon	Leaf buds
(c)	Tuber	Rhizome	Bulb	Leaf buds
(d)	Tuber	Rhizome	Bulbil	Leaf buds

- Which is true about bulbils in Agave
 - (a) It has floral buds modified into bulbils
 - (b) Bulbils germinate while still on inflorescence
 - (c) Bulbils show vivipary
 - (d) All the above
- 13. Transmission tissue is characteristic feature of

[AIPMT (Cancelled) 2015]

- (a) Solid style
- (b) Dry stigma
- (c) Wet stigma
- (d) Hollow style

14. Examine the types of aestivation shown in the following diagram and select the correct answer [NCERT]

- (a) A Twisted, B Imbricate, C Vexillary, D Valvate
- (b) A Imbricate, B Vexillary, C Valvate, D Twisted
- (c) A Vexillary, B Valvate, C Twisted, D Imbricate
- (d) A Valvate, B Twisted, C Imbricate, D Vexillary
- Papilionaceous flower with large vexillum covering two wings and the wings covering the keel has corolla aestivation of
 - (a) Descending imbricate
- (b) Ascending imbricate
- (c) Twisted
- (d) Valvate
- 16. An apocarpous flower is found in

[BHU 1999; JIPMER 2000]

- (a) Caesalpinnia
- (b) Ranunculus
- (c) Brassica
- (d) Datura
- 17. The side of a flower facing the mother axis is called

[RPMT 1992]

- (a) Anterior side
- (b) Posterior side
- (c) Dorsal side
- (d) Ventral side
- 18. Which of the following is not a characteristic feature of Fabaceae [NCERT; Kerala PMT 2007]
 - (a) Descendingly imbricate, ten stamens, diadelphous, ovary superior
 - (b) Sepals five, gamosepalous, imbricate aestivation, placentation marginal
 - Monocarpellary, ovary superior, style long, slightly bent at the apex
 - (d) Zygomorphic flowers, diadelphous stamens, many ovules
 - (e) Corolla five petals, polypetalous, anterior one large and outermost
- 19. Stylopodium is present in
 - (a) Mustard
- (b) Petunia
- (c) Coriander
- (d) Pea
- 20. Basifixed monothecous anthers (OR) anthers with two microsporangia is characteristics of [RPMT 1995]
 - (a) Leguminosae/Pea
- (b) Malvaceae/Cotton
- (c) Solanaceae/Tomato
- (d) Liliaceae/Onion
- 21. Feathery (hairy) style is persistent in
 - (a) Solanum
- (b) Clematis
- (c) Helianthus
- (d) Hibiscus
- 22. In Acacia species, the first few leaves are pinnately compound. Then there are leaves with flattened petiole and fewer pinnae. The leaves of adult plant has parallel veined flattened petiole and no pinnae. It shows that
 - (a) Leaves of adult plant are reduced to phyllodes while those of the seedling are unreduced
 - (b) The parallel-veined green structures of the adult plant are phylloclades
 - (c) The plant shows developmental heterophylly, compound in seedling and simple in adult plant
 - (d) The leaves of adult plant are unreduced while they are reduced in the seedling stage

3.	Hair present on the	cob of corn are	[CBSE PMT 2000]	4.	Assertion	:	Root hairs are present on whole root surface.
	I filamentous t		ng at the end of a young		Reason	:	Root hairs absorb water.
	cob of maize are	illeaus protituui	[CBSE PMT 2006]	5.	Assertion	:	In syconous type of fruit, the achenses
	(a) Seed hairs	(b)	Modified hairs of bracts				formed are fewer than the total number of
	(c) Styles		Stigmas and styles				flowers in the inflorescence from which it is
4.	Diadelphous stame						formed.
**	[CP	MT 1994, 95, 9	8, 99; Pb. PMT 1997, 99] Cucurbitaceae		Reason		Upper and middle flowers cannot develop into fruits. [EAMCET 2009]
	(c) Papilionatae		Malvaceae	6.	Assertion	:	An ascending taxonomic sequence of
5.	Inflorescence is		[AFMC 1994]				Gossypium herbaceum indicates its placement in progressively higher groups.
		ultiple) fruit de	veloped from condensed		Reason	:	Ascending taxonomic hierarchy indicates
	inflorescence	11	a frag camala				that a taxon is treated as belonging to a
	(b) Aggregate fruit						number of taxa. [EAMCET 2009]
	(c) Fruit develop f(d) Fruit develops	from thalamus		7.	Assertion	:	Deep feeder tap root system is called cymose tap root system.
6.	Tetradynamous co				Reason	:	Deep feeder root system is found in trees.
	(a) Androecium (c) Perianth	(d)	Inflorescence Gynoecium	8.	Assertion	:	Coconut tree is distributed in coastal areas over a large part of the world.
27.	Match Column-I option using the co	with Column odes given below	II and select the correct [NEET (Phase-II) 2016] Column-II		Reason	:	Coconut fruit can float and get dispersed over thousands of kilometers before losing viability. [AIIMS 2004]
	(A) Pistils fused to	gether (i)	Gametogenesis	9.	Assertion	:	Orchis root resembles human hand.
	(B) Formation of g (C) Hyphae of hig	gametes (ii)	Pistillate Syncarpous		Reason	:	Orchis is an example of fasciculated flesh
	Ascomycetes			10.	Assertion	,	Momordica roots look like necklace.
	(D) Unisexual fem	ale flower (iv)	Dikaryotic	10.	Reason		Momordica possess moniliform roots.
	Codes (A)	(B) (C) (D)	11.			Assimilatory roots can photosynthesize.
	(a) (iii)	(i) (iv			Reason	:	Asimilatory roots possess chlorophyll.
	(b) (iv)	(iii) (i)	(ii)	12.	Assertion	:	Epiphytes are called space parasites.
	(c) (ii)	(i) (iv			Reason	:	Epiphytic roots possess velamen.
	(d) (i)	(ii) (iv		13.	Assertion	:	Maize is an albuminous seed.
					Reason	:	Endosperm is completely absorbed by it growing embryo.
	A Ass	ertion &	Reason	14.	Assertion	:	In syngenesious stamen, the filaments ar fused and the anther are free.
	K		1100001		Reason	-	In synandrous stamen, both filaments an anthers are fused.
Rea	d the assertion and 1	reason carefully	to mark the correct option	15.	Assertion Reason	:	Stem develops from hypocotyl of embryo. Internodes bear axillary buds.
out	of the options given	below:		16.			Bud may form leaves and flowers.
(a)			on are true and the reason	10.	Reason		Bud is a condensed shoot.
	is a correct explai		ertion are true but the reason is	17.		:	In cymose branching, growth of termin
(b)	not a correct expl	lanation of the a	ssertion		Reason	:	bud stops after some time. The growth of the main stem is definite.
(c)	If the assertion is			18.	Assertion	:	Ginger has a prostrate-growing rhizome.
(d) (e)	If both the asserti If the assertion is				Reason	:	Shoot growth is not effected by gravity. [AIIMS 200
1.			odes but no leaves or buds. rise endogenously.	19.	Assertion	:	Some fruits are furnished with hook spines, barbs or other devices for sticking
2.	Assertion : I		atic plants, root caps are	2	Reason		the body of animals unwillingly. Such fruits are dispersed by animals
	and the second second second		present in aquatic plants.		Heason		unwillingly.
			e similar in all terms to roo	t 20	. Assertion	:	Human travellers also disperse seeds at fruits.
3.		caps.					

UNIVERSAL BOOK DEPOT 1960

21.	Assertion	:	The mesocarp of drupe is edible in all cases.
	Reason	:	Coconut is a fibrous drupe.
22.	Assertion	:	Thorns of Artabotrys are modified floral stalks.
	Reason	:	In Antigonon, the upper floral buds develop thorns.
23.	Assertion	:	Prickles lack vascular cylinder.
	Reason	:	Prickles show deposition of silica or calcium carbonate.
24.	Assertion	:	Wheat is a caryopsis.
	Reason	:	Its pericarp is well differentiated.
25.	Assertion	:	Phyllotaxy deals with morphology of leaves.
	Reason	:	Foliage denotes all leaves of a plant.
26.	Assertion	:	Achenial fruits are single seeded fruits.
	Reason	:	Capsular fruits are multiseeded fruits.
27.	Assertion	:	In spiral phyllotaxy, many leaves are present on a node.
	Reason	:	In opposite phyllotaxy, two leaves are borne on a node.
28.	Assertion	:	A simple leaf has undivided lamina.
	Reason	:	Leaves showing pinnate and palmate venation have various type of incisions.
29.	Assertion		Citrus is a palmate compound leaf.
	Reason	:	Citrus has single functional leaflet.
30.	Assertion		Whole compound leaf of <i>Clematis</i> converts into tendril.
	Reason	:	Gloriosa superba shows whole leaf tendril.
31.	Assertion	:	Prickles of plant have a single role of protection of plant.
	Reason	:	They are superficial in origin.
32.	Assertion	:	Samara is a winged achenial fruit.
	Reason	:	Wings may or may not develop from its pericarp.
33.	Assertion	:	Small leaflets are present on the phyllode of Parkinsonia aculeata.
	Reason	:	Phyllode does not bear leaves and flowers.
34.	Assertion	:	Persistent sepals of Physalis are called accrescent.
	Reason	:	In Guava, the sepals are marcescent.
35.	Assertion	:	An incomplete flower can be perfect.
	Reason	:	Perfect flowers (incomplete) are called neuter.
36.	Assertion	:	The flowers of Hypanthodium are never exposed.
	Reason	:	Hypanthodium flowers are bisexual.
37.	Assertion	:	Heterophylly is seen in many aquatic plants.
	Reason	•	Aquatic plants survive in two different conditions of the environment.
38.	Assertion	:	In caducous plants, leaves are never formed.
	Reason	:	In deciduous plants, all leaves fall together.
20	A		O

Onion leaves are centric and green.

Aerial leaves of onion store food. China rose and rose both bear stipules.

They are of adnate types.

Assertion

Reason

Assertion : Reason :

		-,	BOOK DEPOT 1960
41.	Assertion	:	Verticillaster is a cymose inflorescence.
	Reason	:	The main axis and lateral branches of inflorescence end in flowers.
42.	Assertion	:	Leaves of Bryophyllum, Begonia help in vegetative multiplication.
	Reason	:	Leaves of these plants possess adventitious buds.
43.	Assertion	:	Adiantum caudatum is a walking fern.
	Reason	+	Adiantum grows vegetatively by their leaf tips.
44.	Assertion	:	In corymb, all the flowers lie at the same level.
	Reason	:	Pedicels of all the flowers are of same length.
45.	Assertion	:	Spathe, a bract of spadix attracts pollinators.
	Reason	:	Spathe is often brightly cloloured.
46.	Assertion	:	Flower of racemose inflorescence are pollinated by insects.
	Reason		In Racemose head infloresence, the florets are arranged in a centripetal fashion.
47.	Assertion	:	In cymose inflorescence, the main axis ends in a flower, but the lateral axis show continuous growth.
	Reason	:	The arrangement of flower in this inflorescence is centrifugal.
48.	Assertion	1	Compound umbel is branched.
	Reason	:	In compound umbel, both involucre and involucels are present.
49.	Assertion	:	In cyathium, several male flowers surround

Answers

Reason

a single female flower. The involucre is nectariferous.

Answers and Solutions

Root

 (b) In plants growing in salty marshes some branches of tap root grow vertically upwards into the air from horizontally secondary roots. These roots are called pneumatophores.

- (c) In monocotyledonous plants the radicle dies immediately after germination of seeds and later these roots arise from any other portion (stem, leaves etc.) of the plant.
- 4. (c) Pneumatophores develop from horizontal roots. They bear a number of lenticels or pneumathodes. Exchange of gases occurs through these pores. e.g., Rhizophora.
- (c) In epiphytic roots the outer covering is made up of spongy tissue, the velamen which absorbs moisture from air.
- (b) Swollen adventitious roots of definite shape that occur in groups or fascicles, and arise from base of stem e.g. Dahlia.
- (d) The swollen root is broad at the base and tapers gradually towards the apex.
- 8. (c) The root is nearly globular or spherical in shape. The basal portion of root is much swollen which suddenly tapers towards the apex giving a top shaped appearance, e.g., Turnip and Beet.
- (d) The storage root is like a spindle, narrow towards both base and apex. It occurs in Raphanus sativus. The basal part of it is made of tap root.
- 10. (b) They are thin thread like adventitious roots which often develop in groups. Fibrous roots provide better and firm anchorage to the plant, e.g., Grass.
- 11. (a) In some plants roots arise from lower nodes of stem and enter the soil to provide extra support. They behave as ropes of a tent. Such roots are called stilt or brace roots e.g., Pandanus.
- 12. (c) These roots develop chlorophyll and become photosynthetic. They synthesize carbohydrates from carbon dioxide and water in presence of light, e.g., Trapa, Tinospora, Taeniophyllum and podostemon.
- 15. (c) It is adventitious because it is not formed from radicle.
- 17. (c) Plants belonging to sub-family papilionatae of family leguminosae (e.g., pea, gram etc.) bear nodule-like swellings, called root nodules. These nodules contain nitrogen fixing bacteria which fix atmospheric free nitrogen into ammonia.
- **21.** (a) Some of the adventitious roots store food materials and become swollen. They arise singly and do not attain a definite shape, e.g., Sweet potato (*Ipomoea batata*).
- 28. (a) Pistia is hydrophyte where absorption of water by root is insignificant
- 29. (a) Velamen is a dead spongy tissue of empty cells. It absorbs water present on the surface of these roots.
- 31. (d) Potato is modification of underground stem.
- 33. (d) These roots hang in the air and possess velamen or spongy tissue for absorbing moisture directly from atmosphere. The epiphytic roots are devoid of root hairs and root caps.
- 35. (d) Some aquatic and saprophytic angiosperms have no roots. In aquatic insectivorous plant-Utricularia, some leaves are finely dissected and carry on function of roots.

- (d) Many roots can develop adventitious buds and take part in vegetative propagation, e.g., Dahlia, Dalbergia.
- 38. (d) They are laterally compressed horizontal roots which travel along the ground for some distance and provide extra mechanical support, e.g., Ficus elastica.
- 39. (d) Prop roots of Banyan tree helped it spread in an area of 200 acre in Indian Botanic Garden, Sibpur, Harwrach. This single Banyan tree had 1600 prop roots.
- (c) Such roots are found in plants growing in mangroves or saline swamps near the sea shore.
- **42.** (d) The region of fastest growth is behind the root tip. It is 4-8 mm long portion behind the tip. Here cells elongate rapidly due to vacuolisation.
- 43. (d) Prop or pillar or columnar roots: They are pillar-like roots which give extra mechanical support to heavy stem branches, e.g., Banyan tree.
- 44. (c) In Pothos armatus, Acanthorhiza and Iriartea, some adventitious roots from the base of stem become hard, pointed and thorn like. Those roots are called rootthorns.
- (d) Halophytes or mangroves like Rhizophora, Raxburghiana, Sonneretia etc., have pneumatophores and vivipary.
- 47. (b) Mango, ginger is a modification of adventitious roots. These roots become swollen at their tips due to accumulation of food.
- 48. (c) The roots where adventitious roots become swollen to store food. Fasiculated root is a type of storage root. e.g., Dahlia, Ruellia, Asparagus etc.
- 49. (d) Floating roots are white spongy and arise from node and stem store air. They help in floatation as well as in breathing also, e.g., Jussiaea.
- 52. (d) Many aquatic plants possess elongated loose cap like covering over their tips. They are called root pockets, e.g., Water Hyacinth (Eichhornia).

Stem

- (b) Corm is an underground modification of main stem and stores food materials and becomes tuberous. Buds present externally corms give rise to new aerial shoots and new corms.
- (a) Bulbils are fleshy vegetative buds which store food and take part in vegetative propagation. Bulbils of Agave germinate which still on inflorescence and thus show vivipary.
- (b) Cladode are somewhat similar to phylloclade with the difference that cladode may by made up of only one internode. e.g., Asparagus (Satavar) or two internodes e.g., Ruscus.
- (d) Accessory buds borne at the leaf bases. They are two types: (i) Collateral buds present on the side of axillary bud, e.g., lilies (ii) Superposed buds present above the axillary bud e.g., Aristolochia.
- (b) Thorns are actually modified axillary buds or terminal buds and they possess vascular supply.
- (b) Sweet potato, Carrot Edible root.
 Potato Edible underground stem.

- 10. (d) Pedicel or floral stalks of Artabotrys produces a curved hook (which are modification of inflorescence axis) to help the plant in climbing.
- (b) Phylloclades are modification of stem. These are green fleshy leaf like structure having nodes and internodes. Stem performs the function of photosynthesis.
- 12. (a) In bulb the stem is highly reduced and can be seen only as a disc like structure. On this disc are present numerous fleshy scaly leaves covering a central terminal bud. Both the disc and scaly leaves collectively are called bulb.
- 15. (a) Potato is (underground) stem because on the surface of potato many axillary buds or eyes are formed which are capable of growing into new plant.
- (a) A special type of rhizome which grows vertically is called root stock, for example, Alocasia indica and Musa paradisiaca (Banana).
- 18. (a) Opuntia Phylloclade
- (a) Cabbage represents the largest apical bud. It is a vegetative bud and stores food.
- **20.** (a) Onion Bulb underground stem, Ginger Rhizome *Chlamydomonas* Zoospore.
- 23. (b) Axillary buds developing at nodes/notch/eyes
- 24. (a) The entire bulb is covered by peripheral dry membranous leaf bases called tunics.
- 25. (d) Prickles are superficial (exogenous origin) outgrowths in any part of stem, branch, leaf and do not have vascular supply. Thorns are modified stem and differ from spines and prickles for example, Bougainvillea, Carissa and Duranta.
- 26. (a) Sucker is a sub aerial branch that arises from the main stem. Initially it grows horizontally below the soil surface and later grow obliquely upward. They are shorter and stouter than the runners. e.g., Mentha arvensis and Chrysanthemum.
- 27. (c) In some weak stemmed plants, the axillary bud or terminal bud may modify to form tendrils which are specially called stem tendrils for e.g., Passiflora, Atigonon, Vitis etc.
- (d) Root stock rhizome is oblique or vertical with tip almost reaching the soil surface.
- 32. (d) Ginger (Zingiber officinale) is an example of underground modifications of stem (rhizome) which has nodes and internodes.
- 33. (a) Colocasia is an example of corm.
- 34. (a) The axillary bud or terminal bud may modify to form tendrils which are specially called stem tendrils e.g., Passiflora.
- **36.** (d) The rhizomes are perennial and vegetatively propagating structures and stores food materials and appear tuberous *e.g.*, Ginger, Turmeric etc.
- 39. (c) Vegetative buds or floral buds modify into a swollen structure called bulbils or bulblets. It separates from the parent plant and gives rise to a new plant i.e., it is an vegetative reproduction, e.g., Agave, Oxalis etc.
- 42. (a) In onion food stored in leaf base is glucose.

- 45. (a) Twiners are weak stemmed plants where the stem coils or twines around an upright support. Direction of coiling around the support is specific and genetically determined. The coiling is due to nutation.
- 46. (b) Multicellular hairs is the characteristic of stem.
- (b) Potato is a modification of stem and sweet potato is a modification of root.
- **49.** (d) They store food material in the basal portion and formed new corms e.g., Colocasia, Alocasia.
- 51. (b) Phylloclade is a modification of stem because the stem modifies into green fleshy leaf like structure having distinct nodes and internodes.

Leaf

- (c) Leaf is a thin flattened out growth of the plant arising from the node of the stem and having a bud in its axil.
- (c) The leaves having even number of leaflets are termed as paripinnate, e.g., Cassia, Tamarind etc.
- 6. (d) In grasses and many monocots, the leaf base is broad and surrounds the stem as an envelope, such a leaf base is called sheathing leaf base. An additional outgrowth is present between leaf base and lamina. It is called ligule. e.g., Grasses.
- 7. (b) Victoria regia an aquatic plant with floating leaves. Which are 4 meters in radius and diameter 1.5-1.8 m. These are the largest leaves in plant kingdom.
- (c) Parallel venation is the characteristic feature of monocotyledons. Exceptionally few dicots show parallel venation, e.g., Calophyllum and Eryngium.
- (d) In this type, the primary rachis is divided once and produce secondary rachis. The leaflets develop on the secondary rachis. e.g., Mimosa pudica (Mimosoideae).
- 10. (b) The leaves are modified into slender wire and coiled structures called leaf tendrils. The tendril may be formed by entire leaf e.g., Lathyrus aphaca (Wildpea).
- **12.** (b) Terminal leaflets modifies into tendril. *e.g.*, Lathyrus odoratus (Sweet pea).
- 13. (b) The stipules are the small lateral appendages present on either side of the leaf base. Bud scales stipules are scaly which protect the leaf buds by surrounding them. e.g., Ficus, Artocarpus, Banyan etc.
- (d) The unipinnate leaf with odd number of leaflets. The rachis is terminated by single unpaired leaflet. e.g., Neem, Rose, Murraya.
- **16.** (a) The leaf having single undivided lamina is called the simple leaf. e.g., Peepal.
- 18. (c) When stipules are thin and modified into wire like structure these are known as tendrillar. These help in climbing of plants. e.g., Smilax.
- (b) In Onion and garlic (underground bulb) scale leaves store food and become fleshy.
- 23. (d) In few plants the petioles are modified into tendrils and helps the plant climbing e.g., Clematis and Tropaeolum.
- 31. (a) A leaf is always borne at the node of stem.
- (c) In Utricularia (Bladderwort) some of the leaves are modified to form small bladders (utricles) each of 1-3mm diameter.

- 33. (b) In this type of venation main veins divide into various branches and make a net-like structure in the lamina. It is found in most of the dicot plants.
- 35. (b) The underground stems having central axis, which grows and develops flower on top are called scape e.g., onion, garlic etc. Pedicel is the stalk of the flower. The broadened base of flower which lies at the tip of pedicel is called thalamus or torus.
- **36.** (a) Circinate ptyxis is a folding or rolling from apex to base like spring of watch, e.g., fern leaves.
- (d) Green, flattened petioles may be called winged petioles, e.g., Citrus and Dionaea.
- 38. (a) A pointed structure formed by the modification of entire leaf or part of a leaf is called a spine. Leaf or entire leaf may be modified into spines. e.g., Opuntia (axillary branches are modified into spines).
- **40.** (c) The lamina is modified into broad pinkish pitcher of 1 to 10 inches in length.
- **42.** (b) Because *Mangifera* (mango) is a dicot plant and reticulate venation found in dicots.
- 43. (a) It is the most familiar and wide spread type of compound leaf in which the rachis is elongated and bears two rows of simple or divided leaflets. The leaflets arranged alternately or in pairs along with the rachis.
- 44. (c) Multifoliate (Digitate): A palmately compound leaf having five or more terminal leaflets, e.g., Bombax malabarica, Cleome viscosa, Gynandropsis pentaphylla etc.
- **45.** (a) In parallel venation (striate venation), veins and veinlets run parallel to each other. Parallel venation is the characteristic feature of monocots.
- 50. (d) Membranous tubular stipules that ensheath the axillary bud and a part of internode is called ochraceous stipule. It is formed by the union of two stipules. e.g., Polygonum and Rumex.
- **52.** (a) Only one leaf is found at each node. The leaves present at successive nodes alternate with each other. The arrangement is said to be alternate or spiral.
- **54.** (c) Leaf base (Hypopodium) is the lower most part of the leaf meant for attachment. It acts as a leaf cushion.
- **55.** (d) A pair of leaves at one node stands at right angle to the next upper or lower pair so that four vertical rows are formed on the stem. *e.g.*, *Calotropis*, *Zinnia*, Tulsi, *Quisqualis*.
- 56. (c) In some plants leaves are modified into pointed spines which are known as leaf spines. These protect the plant from grazing animals and reduce the rate of transpiration in xerophytic plants.

Inflorescence

- (d) Capitulum (Head): It is a characteristic of compositae (Asteraceae). Penduncle is flattened to form receptacle that bears centripetally arranged small sessile flowers called florets surrounded by involucre of bracts. e.g., Marigold, Sunflower.
- 7. (a) Flowers are arranged in acropetal succession, i.e., older flowers are towards the base and younger ones are towards the apex of the peduncle.

- (d) Catkin (Amentum) is a compact pendent unisexual spike in which peduncle is thin and weak. e.g., Morus (Mulberry), Populus (Poplar), Acalypha (Cats tail), Salix (Willow), Betula (Birch).
- 12. (a) The florets are surrounded by an involucre of bracts.
- 14. (d) Hypanthodium is a special type of inflorescence formed by the condensation of main axis into a cup or flaskshaped fleshy receptacle.
- 15. (c) Spadix is a modification of catkin spike in which the peduncle is thick and fleshy with upper part sterile (called appendix) and lower part bearing male, neuter and female unisexual flower surrounded by a large bract called spathe. e.g., Musa paradisiaca.
- 16. (c) Spikelet is a compact spike having a few flowers borne an axis called rachilla and surrounded by two bracts called glumes. e.g., Wheat, Oat, Grass. Each flower or floret has at its base a bract called lemma and a bracteole complex called palea.
- (d) Flower occurs singly in the axil of a leaf, e.g., China Rose/ Shoe flower (Hibiscus rosa - Sinensis).
- 21. (b) It is a raceme of verticels or (whorls of flowers) borne on rectangular axis in the axils of opposite leaves. At each node there are two verticels. Each whorl consists of two clusters of 3-9 flowers e.g., Ocimum (Tulsi), Salvia, Leucas.
- (d) Corymb (e.g., Cauliflower), catkin (Mulberry) and hypanthodium (Fig) are edible inflorescence.
- (c) A pendulous spike or spike-like inflorescence consisting of small unisexual flowers, e.g., Morus alba (Mulberry), Salix (Willow).
- (b) More flowers are pollinated at a time, more fruits are produced.
- 28. (a) Corymb of corymbs inflorescence found in Cauliflower. Edible Cauliflower (Brassica oleracea var. Botrytis) represents an undeveloped inflorescence.
- (d) Involucre is whorl of bracts found in capitulum, umbel and cyathium.

Flower

- (d) Hermaphrodite or perfect/bisexual / intersexual / androgynous / monoclinous : A flower having both the essential organs i.e., stamens and pistils. e.g., Hibiscus.
- (a) The broadened base of flower which lies at the tip of pedicel is called torus or thalamus or receptacle.
- 3. (b) Synandrous: Stamens are fused in the region of both there filaments and anthers, e.g., Cucurbita, Luffa.
- (a) Flower is highly modified and condensed shoot meant for sexual reproduction. It is characteristic of angiosperms.
- 6. (c) The fused petals form a strap-shaped structure towards the upper end. A small hairy outgrowth, the ligule is present at the junction of the strap and the tube, e.g., ray florets of Helianthus.
- (c) Beauty of Bougainvillea flower is due to petaloid bract (Brightly coloured petal like bract).
- (a) The flower may be described as complete if it bears all the floral whorls or floral parts.

- 10. (a) Monoadelphous: Filaments of all the stamens are fused to form a tube around the gynoecium. Anthers are free. e.g., China rose.
- (b) When stamens adnate or unite with petals. This
 condition is known as epipetalous. e.g., Petunia,
 Datura.
- **12.** (e) Imperfect or unisexual or diclinous: A flower containing either stamens or pistils *e.g.*, *Luffa*. These are of two types namely staminate which bear the stamens and pistillate bearing pistils.
- **13.** (c) It is the third elongated internode between androecium and gynoecium e.g., Capparis and Gynandropsis.
- (a) A plant bearing flowers of both sexes, i.e., Staminate and pistillate flowers, e.g., Ricinus, Zea mays (maize) and Cucurbits.
- 19. (d) Descending imbricate aestivation in petals are found in Papilionaceae family.
- 23. (d) In Maize, flowers are unisexual but plant is monoecious.
- 24. (c) Foliaceous shape of sepals is present in Mussaenda.
- 26. (b) The bracts found on the rachilla of spikelet are called glumes. They may be sterile glumes or fertile glumes (lemma), e.g., Oryza sativa.
- 27. (d) In many members of Asteraceae family, the sepals are modified into hairs called pappus. e.g., Tridax.
- **28.** (c) Four free clawed petals arranged in the form of a cross, e.g., Mustard and Radish.
- 30. (b) Lodicules are modified tepals (Perianth). Perianth: 2, polyphyllous, small hyaline membranous antero-lateral scales called lodicules, hairy or smooth, whitish, inferior occur in Triticum aestivum.
- **31.** (a) China rose, mustard, brinjal, potato, onion and tuliptotal six plants have superior ovary.
- (c) Gram, Arhar, Sunhemp, Moong, Pea and Lupin belongs to Fabaceae family that bears marginal placentation.
- 36. (b) Ray florets are always unisexual pistillate or neuter in heterogamous head inflorescence. In homogamous head, these are bisexual.
- (c) The terminal receives portion of the style is called the stigma. It receives pollen grain during pollination.
- 39. (d) Perianth is the collective name of the nonessential floral organs if there is no distinction between sepals and petals.
- **42.** (a) Thalamus may show internodes, between various types of floral organs anthophore, androphore, gynophore. This evidence proves that flower is a modified shoot.
- 46. (b) Rafflesia is largest flower (1 meter).
- **48.** (a) Hypogynous flower (hypo = below; gyny = ovary). Thalamus is conical or convex with gynoecium at top and other part below it, ovary is superior and other parts inferior. e.g., Liliaceae, Malvaceae and Solanaceae.
- 49. (b) Epigynous flower: Thalamus is hollowed out and fused with ovary. Other floral organs appear at the top of ovary. Gynoecium is inferior while other parts are superior.
- 50. (c) Gynoecium consisting of two to many free carples. Each carpel forms its own pistil, e.g., Ranunculus, Lotus.

- **54.** (b) The posterior petal is the innermost. It is being overlapped on the margins by lateral petals. The lateral petals are in turn overlapped by anterior petals, e.g., Tamarindus.
- 56. (c) Pappus: (Hairy or feathery sepals) sometimes sepals are modified into hairy structures which are useful in dispersal of seeds. e.g., Compositae / Marigold.
- 70. (b) Perianth is reduced to 2-3 boat shaped membranous lodicules. Lodicules found in family Gramineae (Poaceae).
- 71. (b) When stamens mature earlier than the stigma, it is known as protandry and the flowers are called protandrous e.g., Coriander, Jasmine, Sunflower etc.
- 72. (c) Filaments of a stamens are fused forming one bundle and the other bundle is represented by the filament of the tenth free stamen $A_1 + (9)$.
- 73. (b) Stamens inserted in two whorls: Outer whorl is opposite to petals, i.e., antipetalous. Whereas inner whorl is alternipetalous e.g., Dianthus.
- 77. (c) The plants of some species in which flowers are dimorphic. Thus facilitate cross pollination. Some of them possess a long style but short stamens and are known as pin-eyed while others have short style and long stamens. These are known as thrum-eyed. e.g., Primrose.
- 78. (a) Cocus nucifera belongs to family Arecaceae. In this family, flower containing either stamens or pistils. The floral parts are in multiples of three.
- 80. (d) The corolla of Hibiscus is polypetalous and twisted. Hibiscus is the member of family Malvaceae. Malvaceae comes under series thalamiflorae of class polypetalae. The petals are 5 and free. The aestivation of coralla is twisted in this family.
- **82.** (d) Petals are 5, free, and twisted aestivation are found in china rose.
- (c) Datura, mustard and tomato have actinomorphic flowers.
- (a) Tomato Berry, Orchid seed no endosperm formation, Primose Free central placentation
- 93. (b) Ovary is half inferior in perigynous flowers.
- 101. (d) Imbricate aestivation Cassia, gulmohur.
- 104. (c) The stamens may be united into one bundle (monoadeplhous), or two bundles (diadelphous) or into more than two bundles (polyadelphous).
- 105. (b) Radial symmetry is found in flowers like mustard, Datura, Chilli.

Seeds and Fruits

- (d) The orchids seeds (0.004 gm) are smallest in Angiosperms. These are small, dry and light and can be carried by wind to over 1000 km.
- (b) Seed is a fertilized and ripened ovule (mature integumented megasporangium) found in phanerogams (spermatophytes).
- (a) The main body of the ovule is covered with one or two envelopes called integuments.
- (a) Viability of seeds: Ability of seed to have power of germination over a period of time is called viability. It is maximum in Lotus (Nelumbo nucifera)i.e., 400–2000 years.

- (b) Morphological dormancy-embryo is small & under developed.
- **12.** (a) The fertilized ovule forms seed. The ovule increases greatly in size. The integuments dry up.
- 13. (c) Non-endospermic or Exalbuminous seed: Endosperm is completely consumed by the developing embryo and the mature seeds are without endosperm. The food is stored in cotyledons. e.g., Gram, pea, Bean etc.
- 14. (b) Vivipary is germination of seeds within fruit (in situ) while attached to the parent plant. Hypocotyl elongates and pushes the radicle but the seed and fruit hangs like Damocle's sword from the tree. It is found in mangroves (e.g., Rhizophora, Sonneratia).
- 15. (b) Rhizophora is a mangrove plant and vivipary is found in it.
- (b) The mesocarp is thick, fleshy, juicy and edible part in Mangifera (Mango).
- 17. (a) Berry type of simple succulent fruits the pericarp divided into three layers a thin delicate outer epicarp, a soft middle mesocarp and an inner layer known as endocarp. Both endocarp and mesocarp are fleshy. The slippery, oval, orange, coloured seeds are attached by stalks to the placenta. e.g., Tomato, Brinjal.
- 18. (c) Caryopsis: It is very small dry and one seeded fruit which develops from a superior monocarpellary ovary. Here the pericarp is closely fused with seed coat. It is the characteristic of family graminae. e.g., Wheat, Maize.
- (a) The aggregate fruits are formed from polycarpellary, apocarpous ovary of a single flower. e.g., Michellia, Rubus, Annona.
- 20. (c) Caryopsis is one-seeded dry indehiscent fruit developed from a monocarpellary, unilocular and superior ovary. e.g., Wheat, Maize, Paddy.
- 21. (d) Hesperidium is many chambered and many seeded fleshy fruit developed from multicarpellary, syncarpous and superior ovary. The epicarp is leathery and glandular, mesocarp is thin and smooth, e.g., Lemons and oranges.
- 25. (c) Lomentum is a type of fruit. It is a dry many seeded fruit which develops from a monocarpellary, superior, unilocular ovary with marginal placentation.
- 28. (c) The fruit of Datura is septicidal capsule but its dehiscence is of septifragal nature in which placenta remains attached in the centre of undivided fruit and pericarp's segment becomes separated.
- 29. (d) The structure present within the seed coat is called kernel. Endosperm, embryo and cotyledon are the part of kernel.
- (b) Mechanical scarification (Rupturing of seed coats) by filling, chipping or machine threshing.
- 31. (d) Castor is an endospermic (Albuminous seed). In albuminous seeds, embryo not consumed all endosperm. So it persists in the mature seed. In these seeds food stored in endosperm. In castor, the cotyledons come above the surface of the soil into the air and light due to the rapid growth and elongation of the hypocotyls. The cotyledons turn green and finally dry up and fall off and seedling becomes an independent plant. It is a type of epigeal germination.

- 32. (b) Pepo is a special type of berry, the epicarp and thalamus form the outer ring of the fruit. The mesocarp, endocarp and placenta are fused to form pulp which is edible. e.g., Members of cucurbitaceae family.
- **34.** (a) Water is of primary importance in germination. When seed protoplasm absorb the water, seed resumes vigourous physiological activities. The embryo bursts through the seed coats. O_2 is also necessary for respiration and other physiological activities.
- (b) Simple fruits develop from monocarpellary ovary or multicarpellary syncarpous ovary.
- **37.** (a) The pericarp of drupe consists of a thin epicarp (forms the skin), a fleshy mesocarp (forms the edible part) and hard and stony endocarp e.g., Cocos nucifera.
- 38. (d) Seeds of some species are edible e.g., Pinus gerardiana (chilgoza pine). This plant is common in dry valley North West Himalayas and Kashmir.
- 39. (c) Sorosis develop from spike, spadix or catkin inflorescence. Bracts, perianth and seed become simple and are used for eating in pine apple and mulberry.
- 47. (d) Fig- developed by hypanthodium inflorescence. pineapple- developed by spike inflorescence. Mulberry-developed by catkin inflorescence.
- 52. (a) Hesperidium is a modification of berry. It develops from a polycarpellary syncarpous, superior ovary with many seeds.
- 62. (a) Mango seeded fruit

 Sterile stamen staminode

 Seeds in grasses endospermic.
- 65. (b) Tomato Berry, Wheat Caryopsis, Pea Legume.
- **74.** (b) Seed of garden pea is ex-albuminous or non endospermic.

Dispersal of fruits and seeds

- (a) In legumes the dry pods split open into two valves which undergo spiral twisting to throw the seeds e.g., Pea, Abrus.
- 3. (b) One or more tufts of hairs attached on seeds constitute coma e.g., Calotropis. Calotropis is insect pollinated but dispersed by wind. Its seeds are plumed (hairy). It has pollinia containing anther to be carried by insects.
- (b) The fruits of Clematis and Naravella possess persistent hairy styles which help in floating in air.
- 5. (d) Autochory (Dispersal by explosion) is self dispersal of the seeds which occurs when the fruit splits up at maturity. Such fruits open with force and scatter the seeds in all directions.
- 6. (a) In Ruellia and Justicia (Acanthaceae) the exposed seeds are thrown away with the help of Jaculators (Jaculator mechanism). Jaculator is a curved hook at the base of seed which open with jerk to throw seeds.
- 7. (d) In members of the family Asteraceae, sepals are modified into tufts of hairs called pappus. The pappus is persistant and hence found attached to even small, single seeded fruits. It acts like a parachute that allows the wind to carry them to great distances.

- (a) The fruit and seeds surface possesses sticky glands for attaching to the body of animals, e.g., Plumbago, Boerhaavia, Cleome viscosa.
- 9. (b) Seed bear hair all around.
- (b) The fruit of Asteraceae often possess pappus (persistent hairy calyx) which functions as a parachute for dispersal.
- 11. (c) The surface of many fruits is covered with hooks (e.g., Xanthium, Urena), spines (e.g., Tribulus) bunch of stiff hair or barbs (e.g., Aristida) by means of which they adhere to the body of animals or clothes of human beings and they are carried unwairly from one place to another.
- 12. (d) Fruits of Bignonia are dispersed by birds.
- 13. (b) Sticky seeds of Rafflesia are dispersed by elephants.
- 14. (d) Human beings and birds are active and useful agent in distributing these fruits.
- (c) The seeds of Moringa (Drumstick), Oroxylon, Cinchona and Pinus are winged. The dispersal of seeds by wind is called anemochory.
- 16. (d) Seed and fruits possess air cavities to keep them a float on water e.g., spongy seed coat of water lily (Nymphaea), aril in the seed of water lily help seeds to float in water by giving buoyancy and fleshy, aril or a kind of third integument is edible part of Litchi.
- (b) In many fruits, testa is modified to form wings as in Cinchona, Oroxylam, Moringa, Swietenia and Largerstroemia.
- **18.** (c) Censer mechanism occurs when seeds are dispersed from small pores in the fruits by swinging in air. e.g., Papaveraceae (Poppy), Aristolochia and Aconitum.

Taxonomy of Angiospermic plants

- 1. (b) Floral formula of Allium cepa (onion).
- 2. (a) Fabaceae commonly called Legume family; 4th largest and 2nd most valuable family. It has a 600 genera. Poaceae commonly called cereal / grass family; 3rd largest family but Indian flora, they constitute the largest family (620 genera).
- (d) Family cucurbitaceae belongs series calyciflorae (sepals are fused or free, ovary is usually inferior) and order passiflorales.
- (c) Touch me not (Mimosa pudica) belongs to sub family mimosoideae. It comes under Papilionatae (fabaceae).
- (b) Liliaceae commonly called lily family; belong to monocotyledons. Perianth (calyx and corolla undifferentiated), biseriate (2- whorled) and petaloid.
- 8. (c) Compositae (Asteraceae) is the largest family of plant kingdom, represented by 950 genera and 20000 species, plants mostly herbs stem with latex / oil ducts and most evolved and advanced among dicot.
- (d) All stamens of a flower fuse by their filaments to form a single staminal tube e.g., family Malvaceae (Hibiscus).
- (a) In family Compositae (Asteraceae) 2 stamens, epipetalous, syngenesious, dithecous, bilobed, introse, filament free.

- (c) Cajanus cajan (Pigeon pea / Red gram / Arhar) belong to family Leguminosae (fabaceae).
- (b) Poaceae (Gramineae) is the 3rd largest but economically most valuable family as it provides cereals and millets.
- 16. (a) Carthamus tinctorius (safflower) belongs to family Asteraceae. It yield Safflower / Kusum oil containing 73% PUFA (Poly unsaturated fatty acids) its good for heart patients.
- (c) Cauliflower is an apical bud belonging to family Cruciferae (Brassicaceae).
- 18. (c) Commonly called mustard family: Plants predominantly herbs and sulphur smelling being rich in sulphur rich glucosides like sinigrin and hence are pungent.
- 20. (b) Family Asteraceae belongs to subclass Gamopetalae (The petals are fused, stamens are epipetalous, carpel may be syncarpous or apocarpous) and series – Inferae (ovary is inferior and stamen usually equal to petal lobes).
- 21. (c) Axile placentation: In a multicarpellary syncarpous gynoecium the fusing margins grow inwards to meet in the center of the ovary to form an axis thus making the ovary multilocular. The ovules are borne on the central axis. e.g., Family Solanaceae and Liliaceae.
- 22. (d) In Fabaceous (Papilionaceous) corolla has petals 5, polypetalous, the posterior petal is largest (standard) and two laterals are wing and inner two anterior are fused to form a boat shaped structure called keel or carina.
- (b) Eleusine coracana (Finger millet/Ragi) is hardest millet and its grains are free from pericarp.
- **26.** (b) Placentation parietal but bilocular due to false septum or replum in *Brassica campesteris*.
- (a) Anterior petals are fused to form a boat-shaped structure called keel or carina.
- 29. (c) Sepals 4, polysepalous, arranged in two whorls, outer of antero-posterior sepals and inner of lateral sepals, lateral sepals generally saccate or pouched at the base, green or petaloid, inferior.
- (d) Commonly called sunflower, largest family of plant kingdom, represented by 950 genera and 20000 species.
- (c) Allium sativum (garlic), Allium cepa(onion) and Aloe vera belongs to family Liliaceae.
- (a) Allium cepa belongs to monocot family Liliaceae, when remaining three are dicot.
- (b) Corm of Colchicum autumnale is source of an alkaloid colchicine used to induce polyploidy.
- (c) Parthenium hysterophorus (carrot grass / congress grass), a most nasty weed, came into India from USA during congress rule in 1950's along with wheat.
- 38. (d) Epipetalous (Epiphyllous): Stamens adnate with tepals. Syngenesious (synantherous): Anthers fused, filaments free in a flower.
- 39. (b) Cereals are one seeded fruit called caryopsis. They are rich in carbohydrate, poor in lysine and tryptophan. Cereals comes under family Poaceae.
- (d) Cajanus cajan is leguminous plant belongs to family Leguminosae. It has root nodules by which they can fix atmospheric nitrogen.

- (a) All pulses belong to family Fabaceae. This family is known for protein rich pulses.
- (c) Flower of family Solanaceae is bracteate or ebracteate, pedicellate, complete, hermaphrodite, actinomorphic, pentamerous, hypogynous.
- 47. (c) Bracteoles modify into palea.
- 56. (d) Petals 4, polypetalous, arranged in one whorl and alternate with sepals, often with long claws and spread out in the form of a Greek cross. This arrangement of petals is known as cruciform arrangement.
- 59. (c) In this type of placentation, the ovary is simple, unilocular and the ovules are arranged along the margin of the unilocular ovary. The placenta develops along the ventral suture of the ovary. e.g., Pea, Gram.
- 61. (b) Pea-Diadelphous
- **62.** (c) Under- developed, sterile stamens non-functional that do not produce pollens, e.g., Salvia, Cassia.
- 63. (d) Parietal Ex. Mustard
 Free central Ex. Primula and Dianthus
 Marginal Ex. Pea
 Axile Ex. Tomato, lemon, Chinarose
- **64.** (c) Leguminosae family possess marginal and Cruciferae possess parietal placentation.
- 65. (c) In Leguminosae ovary is superior.
- 78. (d) Tetradynamous condition of stamens is found in mustard (Brassica campestris) plant of family Cruciferae (Brassicaceae). In tetradynamous condition four stamens remain long and two short.
- 79. (b) In diadelphous condition, stamens are arranged in two bundles. Diadelphous stamens are the characteristic features of family Fabaceae.
- (d) Brassica nigra (Black mustard) comes under Cruciferae (Brassicaceae) family.
- 84. (b) There are six free stamens, inner four are large and outer two are small, e.g., Mustard, Iberis (Cruciferae family).
- 86. (b) In solanaceae bilocular, axile placentation, ovary obliquely placed due to rotation of posterior ovary towards right side and anterior carpel to left side by 45°. Placentae highly swollen, ovules are maximum per locule in this family.
- 87. (c) On the basis of characters of corolla (symmetry) of flower, type of petals and their fusion and aestivation) and androecium (No. of arrangement), this family is divided into 3 sub families.
- 88. (c) The bacteria (Rhizobium spp.) associated with the root nodules of legumes fix atmospheric nitrogen.

Critical Thinking Questions

- (d) In plants like Arceuthobium, Rafflesia, Sapria, Podostemon, shoot develops for flowering otherwise roots form main part of the plant.
- (a) Aggregate of small berries, e.g., Custard apple. Apical parts of berries fuse with each other to form a common rind.
- (c) Onion Bulb Underground stem-Imbricate aestivation-Axile placentation - Member of Liliaceae.

- 7. (a) Cladodes (Cladophylls): They are green photosynthetic stems of limited growth (generally one internode only) with leaves reduced to scales or modified into spines, e.g., Ruscus, Asparagus.
- 10. (a) Some plants never open to ensure complete self-pollination. This condition is called cleistogamy e.g., Commelina bengalensis, Oxalis, Viola, etc. The cleistogamous flower are bisexual small, inconspicious, colourless and do not secrete nectar.
- 12. (d) Bulbils are fleshy buds produced in the axil of foliage leaves in place of axillary buds. In century plant (Agave sp.) the floral buds are modified into bulbils which grow into new plants when shed from the mother plant.
- 15. (a) Descending imbricate or Vexillary aestivation: The posterior large standard petals overlaps the lateral petals called wings or alae on the margins while the lateral wings overlap the anterior keel or carinal petals, e.g., Pea, Gram.
- (b) Apocarpous: Gynoecium consisting of two to many free carpels. Each carpel forms its own pistils, e.g., Ranunculus.
- 17. (b) Mother axis: The shoot on which the flower is borne is called mother axis. The side of the mother axis is always posterior while the side of the bract is anterior.
- (c) Stylopodium : Swollen base of style in Umbelliferae (Apiaceae).
- 20. (b) In Malvaceae/cotton anther single-lobed, 2 chambered (bisporangiate), connective is absent. Filament is attached to the base of the anther.
- **21.** (b) Hairy styles: The fruits of *Clematis* possess persistent hairy styles which help in floating in air.
- 22. (a) In several species, of Australian Acacia (e.g., A. melanoxylon, A. auriculiformis), the petiole and part of rachis expands to form phyllode. Phyllodes are vertical, have fewer stomata and therefore, lose less water in transpiration.
- 23. (d) Stigma feathery or papillate. Silken threads of Maize are very long stigmas but some authors regard them as long styles bearing equally long stigmas in the apical region.
- **24.** (c) Diadelphous: The filaments are united forming two bundles, *e.g.*, in *Lathyrus* (sweet pea), *Pisum* (edible pea) there are 10 stamens; filaments of 9 stamens are fused forming one bundle and the other bundle is represented by the filament of the tenth free stamen $(A_1 + (9))$.
- 25. (a) Composite fruits: These fruits are developed from the complete inflorescence and are known as infructescence. These are of 2 types:
- (1) Sorosis(2) Syconus or Syconium26. (a) Tetradynamous: There are six free stamens, inner four are large and outer two are small, e.g., Brassica (mustard).

Assertion and Reason

 (e) Root is typically a non green underground cylindrical structure forming the descending axis of the plant which gives rise to endogenous branches and does not possess nodes, leaves or buds. Presence of nodes and internode is the characteristic feature of stems.

- 2. (b) The root cap protects the root meristem from friction of the soil particles. In this process, its outer cells are continuously peeled off and replaced by new cells formed from root meristem. In floating aquatic plants the root apices possess finger glove-like coverings called root pockets instead of root cap.
- (d) Root pockets are found in floating aquatic plants. They
 act as balancers. They are structurally similar to root
 caps but differ from them in the fact that the damaged
 root pockets are not regenerated.
- (e) Root hair zone is 1-6 cm in length. The root hairs increase the exposed surface of the root for absorption of water and minerals.
- 5. (a) Syconous fruit develops from hypanthodium inflorescene in which 3 types of flowers are found i.e., male, female and sterile gall flowers. Male flowers and gall flowers cannot develop into fruits. So in syconous type of fruit, the achences formed are fewer than the total number of flowers in the inflorescence.
- 6. (a) G. herbaceum belongs to family-Malvaceae. Taxonomic hierarchy is the system by which various taxonomic categories are arranged in a proper descending order. The ascending taxonomic hierarchy shows that a taxon belongs to a number of taxa and its placement in progressively higher groups.
- 7. (e) Deep feeder tap root system has an elongated tap root which penetrates the deeper layers of the soil. It is mostly met in trees. Deep feeder tap root is also called racemose tap root system. In surface feeders the tap root does not elongate very much. The secondary roots spread to a greater extent. Such a system is also named as cymose tap root system.
- 8. (b) Coconut require the hot and wet climate hence it is grown in coastal areas. It is widely grown in coastal and deltic regions of tropical and subtropical countries.

 Coconut fruit show hydrochory i.e., the dispersal takes place through water medium. Being the habitat of coastal area the fruit is so adapted that it can float and dispersed over thousand of kilometers before losing viability.
- 9. (c) The fleshy roots are thickened like the palm of human hand. They similarly possess finger like outgrowth, e.g., Orchis. They are Palmate roots. Fasciculated fleshy roots are the swollen roots or root tubers occurring in clusters.
- 10. (a) Moniliform or beaded roots are swollen at regular intervals like beads of a necklace. Hence the roots has the appearance of necklace. Such roots are found in Discorealata, Momordica charauter etc.
- 11. (a) Assimilatory roots are green roots (as they contain chlorophyll) which are capable of photosynthesis. e.g., Taeniophyllum, is a leafless epiphytic orchid with thick flattened photosynthetic roots.
- 12. (b) Epiphytes live on the surface of other plants for shelter and space only, hence also called space parasites. Epiphytic roots possess a covering of dead spongy tissue known as velamen. With the help of velamen, they are able to absorb water from moist atmosphere, dew and rain.

- 13. (c) Albuminous seeds are those where endosperm is present, as in maize and castor bean. The endosperm persists in their seeds. In exalbuminous seeds, the endosperm is completely absorbed by the growing embryo and the food reserve gets stored in the cotyledons.
- 14. (e) In syngenesious condition when the stamens are united by their anthers only, the filaments remaining free. In synandrous, stamens are fused by both these filaments as well as anthers.
- 15. (d) Stem is usually the above-ground erect ascending part of the plant body that develops from the plumule, grows by means of a terminal bud and shows distinction of nodes and internodes. The nodes bear leaves having axillary buds.
- 16. (a) A bud is a condensed immature or embryonic shoot having a growing point surrounded by closely placed immature leaves. The largest bud is cabbage. According to their nature, buds can be vegetative, reproductive and mixed.
- 17. (a) In cymose branching the growth of the main stem is definite, that is the terminal bud does not continue to grow, but lower down, the main stem produces one or more lateral branches which grow more vigorously than the terminal one. In some plants the terminal bud gets modified into a flower, tendril, thorn etc.
- 18. (b) Ginger is horizontal in position and generally branched and producing aerial leaves or shoots aboveground and adventitious roots on lower side in favourable season. Thus shoot growth is not effected by gravity.
- 19. (a) Many fruits are provided with hooks, barbs, spines, bristles, stiff hairs etc., on their surface by means of which they adhere to the body of woolly animals as well as to the clothing of mankind and are often carried by them to distant places. The animals are forced to carry such fruits and seeds, e.g., forced zoochory.
- 20. (b) Human travellers have always taken plants from one area to another. Potato was brought from New World by the Portuguese. Many economically important crops and plants such as maize, tobacoo, groundnut, chillies, tea, cabbage, cauliflower, rubber etc. are dispersed by man, as they have been introduced to new areas from their original home. However, many weeds are also dispersed alongwith useful plants.
- 21. (e) The pericarp of drupe is differentiated into epicarp, mesocarp and endocarp. Endocarp is stony. Hence drupes are also called stone fruits. Coconut called fibrous drupe due to fibrous mesocarp, possesses edible endosperm. Among drupes, the mango has edible mesocarp, cherry, peach, plum and Zizyphus have edible epicarp and mesocarp.
- 22. (c) The pedicles or floral stacks of Artabotrys are modified into stiff curved thorns or hooks for helping in climbing. In Antigonon the flowers occur in bunches in the axils of scale leave on the floral shoot. The upper floral buds develop into tendrils instead of forming flowers.

- 23. (c) Prickles are superficial outgrowths of stem or leaves which do not possess a vascular cylinder. They can be easily pulled off. Bristles are stiff hair which become thickened due to deposition of silica or calcium carbonate.
- 24. (c) Caryopsis is a superior achenial fruit where testa and pericarp are inseparably fused, e.g., wheat, maize etc. Achenial fruits are single seeded indehiscent dry and simple fruits. The pericarp is dry and undifferentiated. The pericarp of wheat is thus dry and it is fused with testa.
- 25. (e) Leaf is a green, dissimilar exogenous lateral outgrowth which is borne on the node of a stem or its branch and is specialised to perform photosynthesis. All the green leaves of a plant are collectively called foliage. Phyllotaxy is the arrangement of leaves on the stem or its branches.
- 26. (b) Achenial fruits are single seeded indehiscent dry and simple fruits. The pericarp is dry and undifferentiated. Capsular fruits are many seeded dry and simple fruits in which the pericarp splits open to expose the seeds.
- 27. (e) In spiral arrangement, each node bears a leaf and the leaves of the adjacent nodes roughly lie towards the opposite sides. In opposite arrangement, two leaves are borne on the opposite sides of a single node. When three or more leaves develop on the nodes, they form whorled arrangement.
- 28. (b) A leaf having a single or undivided lamina is called simple leaf. The lamina can have different types of incisions, which may reach upto half (-fid), more than half (-partite) or near the base or midrib (-sect). Depending upon the pinnate or palmate venation, the incisions are known as pinnatifid palmatifid, pinnatipartite, palmatipartite, pinnatisect and palmatisect.
- 29. (b) The palmate compound leaf is one in which the petiole bears leaflets at the tip like the fingers of the palm. Citrus is actually a palmate compound leaf where the two lateral leaflets have been suppressed and only the central leaflet is functional. Such a palmate compound leaf, with one functional leaflet is called unifoliate compound leaf.
- 30. (c) The petiole, rachis and the stalks of the leaflets in Clematis are sensitive to contact and can coil around the support to help the plant in climbing. In whole leaf tendril, the whole leaf is modified into a tendril for climbing. The leaf apices of Gloriosa superba are greatly elongated to function like the tendrils.
- 31. (e) Prickles are defensive organs of plants but prickles being usually curved are commonly used for climbing. They are superficial outgrowths of stem or leaves which do not possess a vascular cylinder.
- 32. (c) Samara is an achenial fruit having winged pericarp, e.g.

 Ulmus (Elm). Achenial fruits are single seeded indehiscent dry and simple fruits. Achenial winged fruits are called samaroid if the wings develop from places other than pericarp, e.g., sepals in Shorea.
- 33. (b) Phyllodes do not bear leaves, branches, flowers, etc. In Parkinsonia aculeata, the rachis ends in a spine. Rachis branches are elongated, flattened and green to function as phyllodes. They bear small leaflets which fall off very easily.

- 34. (b) Persistent sepals are called accrescent it they grow along with the fruit (i.e., Physalis). They (persistent sepals) are marcescent when they assume a dried up form before being shed, i.e., Guava.
- 35. (c) A flower is regarded as complete if it has all the four floral whorls, i.e., calyx, corolla, androecium and gynoecium. If any of these whorl in missing the flower is described as incomplete. An incomplete flower can either be perfect, having male as well as female sex organs or imperfect with either of the sexes missing. When both the essential organs are absent, the flower is spoken as neuter.
- 36. (c) Hypanthodium has a flask shaped fleshy receptacle which possesses a narrow canal and a terminal pore at one end. Internally the receptacle bears male flowers towards the pole and female flowers towards the pole and female flowers towards the base. Sterile, neuter or gall flowers occur in between the two groups.
- 37. (a) Heterophylly is met within many aquatic plants, particularly in those growing in shallow running water. Here the floating or aerial leaves and the submerged leaves are of different kinds; the former are generally broad, more or less fully expanded and undivided or merely lobed; while the latter are narrow, ribbon-shaped, linear or much dissected. Examples are Sagittaria, Ranunculus aquatilis, Limnophila heterophylla.
- 38. (e) In caducous, leaves fall down soon after their appearance, e.g., Opuntia. In deciduous almost all leaves fall off almost simultaneously at the end of growing season. The phenomenon is called leaf fall, e.g., Mulberry, Poplar. In Euphorbia royleana the leaves are drought deciduous.
- 39. (b) When the leaf is more or less cylindrical and directed upwards or downwards, as in onion such leaf is called centric leaf. A centric leaf is equally illuminated on all sides and, therefore, it is evenly green. Centric leaves of onion is aerial. It is underground scale leaves of bulb which store food.
- 40. (c) China-rose has free lateral stipules and rose bears adnate stipules. Free lateral stipules are free stipules, usually small and green in colour, borne on the two sides of the leaf-base. Adnate stipules are two lateral stipules that grow along the petiole upto a certain height, adhering to it and making it somewhat winged in appearance.
- 41. (a) Cymose inflorescence is the name of determinate or definite inflorescence in which the tip of the main axis terminates in a flower and further growth continues by one more lateral branches which also behave like the main axis.

Verticillaster is a special form of cymose inflorescence. The first axis ends in a flower, it bears two lateral branches, each ending in a flower, succeeding lateral branches are produced in an alternating manner.

- 42. (a) Leaves of a number of plants develop or possess adventitious buds for vegetative propagation, e.g., Bryophyllum. Begonia leaf develops buds only when the leaf is injured or detached.
- 43. (a) Walking ferns (e.g., Adiantum caudatum) reproduce vegetatively by their leaf-tips. Leaves bow down to the ground, their tip strikes roots and forms a bud which grows into a new plant.
- 44. (c) In corymb, the main axis is shortened and lower flowers have much longer stalks or pedicels than the upper ones so that all the flowers are brought more or less to the same level. Corymb inflorescence is found in Cassia sp.
- 45. (a) The spadix contains a large green or coloured bract called spathe. For example, in banana and aroids, the brightly coloured spathe attracts insects to facilitate pollination.
- 46. (b) In racemose head, the main axis or receptacle is suppressed, becoming almost flat. It bears a mass of small sessile flowers (florets) on its surface, with one or more whorls of bracts at the base forming an involucre. The florets are arranged in a centripetal fashion, i.e., younger towards the centre and older towards the periphery. The advantages of this kind of inflorescence are that the head as a whole becomes more showy and attractive and the florets being close together, one or a few insects can pollinate most of them within a short time.
- 47. (e) In cymose inflorescence, the main axis ends in a flower and similarly the lateral axis also ends in a flower. Thus the growth of each axis is checked. In cymose inflorescence, the terminal flower is always older and opens earlier than the lateral ones, i.e., the order of opening of flowers is centrifugal.
- 48. (b) Compound umbel is branched umbel, where several small or daughter umbels arise from a common point in an umbellate fashion. A whorl of bracts, called involucre is present at the base of the daughter umbels are called involucels.
- 49. (b) Cyathium is a special kind of inflorescence found in Euphorbia, i.e., Poinsettia and Euphorbia.
 In cyathium there is a cup – shaped involucre, often provided with nectar – secreting glands. The involucre

encloses a single female flower in the centre, seated on a comparatively long stalk and a number of male flowers around this, seated on short slender stalks.

ET Self Evaluation Test

A plant which lives for a few days is called [Odisha JEE 2004] (a) Annual (b) Perennial (d) Ephemeral (c) Biennial Perianth in the spikelet of jawar is represented by (a) Lodicules (b) Sepals and petals (c) Glumes (d) Lemma and palea [MHCET 2004] Heterostyly is show by (a) Primula (b) Mirabilis (d) China rose (c) Helianthus Which is odd one [MHCET 2004] (b) Maize (a) China rose (c) Mango (d) Sunflower Bicarpellary syncarpous gynoecium, parietal placentation, 5. tetradynamous stamens and siliqua fruit are characteristic [CBSE PMT 1992; features of family APMEE 1993; RPMT 1994, 95; CPMT 1998] (a) Cucurbitaceae (b) Cruciferae (d) Solanaceae (c) Compositae What name has been assigned to the genus produced by a 6. cross between cabbage and radish [BHU 2004] (a) Secale (b) Bursa pastoris (d) Raphano brassica (c) Lysogenicophyll The condition where filaments and anthers are fused 7. [Odisha JEE 2004] throughout the entire length is (b) Gynadrous (a) Synandrous (c) Protandrous (d) Syngenesius 8. In a seed of maize, scutellum is considered as cotyledon because it [AIEEE Pharmacy 2004] (a) Protects the embryo (b) Contains food for the embryo (c) Absorbs food materials and supplies them to the embryo (d) Converts itself into a monocot leaf [Odisha JEE 2009] Ephemerals are drought (a) Loving (b) Enduring (d) Resistant (c) Escaping [DUMET 2009] In a monoecious plant 10. (a) Male and female sex organs are on different individuals (b) Male and female gametes are of two morphologically distinct types (c) Male and female sex organs are on the same individual (d) All the stamens are fused to form one unit. [MP PMT 2009] Viral infection is usually absent in (b) Xylem cells (a) Phloem cells (c) Pith cells (d) Apical meristem

Transparent hairs on catkins and caterpillars function to

(b) Fused structure of mesocarp and endocarp

(c) Fused structure of epicarp and mesocarp

(a) Trap heat

(a) Endocarp

(d) Epicarp

(c) Reflect light

13. In coconut fruit, the hard shell is

[Odisha JEE 2008]

IMP PMT 20101

(b) Trap moisture

(d) Drink water

- 14. Ginger multiplies vegetatively by (a) Tuber (b) Corn (c) Sucker (d) Rhizome The floral formula for Malvaceae is (a) $\oplus \bigcirc^{r} \text{Epi}_{(3-7)} K_{(5)} C_{(5)} A_{(\infty)} G_{(5)}$ (c) \oplus \bigcirc Epi₍₃₋₇₎ $K_{(5)}$ $\widehat{C_5}$ $A_{(\infty)}$ $G_{(5)}$ (d) $\oplus \overset{r}{\downarrow}$ Epi₍₃₋₇₎ $K_{(5)} \overset{\frown}{C_{(5)}} \overset{\frown}{A_{(\infty)}} G_{(3-\infty)}$ 16. A monocot showing reticulate venation is [APMEE 1995] (b) Smilax (a) Bombusa (d) Ginkgo (c) Callophyllum 17. Chief feature of family Brassicaceae/Cruciferae is presence of [APMEE 1994; BHU 2002] (a) Latex (b) Pectin (d) Myrosin enzyme (c) Alkaloids In Gloriosa (Glory lily) the tendril is formed from (a) Stipule (b) Leaf apex (c) Axillary bud (d) Leaf [NCERT: Kerala PMT 2007] Select the wrong statement (a) Persistent calyx is seen in Solanaceae (b) Flowers are hypogynous in Asteraceae (c) Santonin is obtained from Artemisia (d) In poaceae, perianth is represented by membranous scales called lodicules (e) Parietal placentation is characteristic of Brassicaceae Largest inflorescence is found in (b) Populus (a) Acalypha
 - Choose the correct description depicted by floral diagram [NCERT; KCET 2002]

(d) Cabbage

(c) Amorphophallus

- (a) United valvate sepals, free twisted petals, free stamens, unilocular ovary with marginal placenta
- (b) United valvate sepale, free imbricate petals, free stamens, unilocular ovary with axile placenta
- (c) United valvate sepals, free imbricate petals, epipetalous stamens, unilocular ovary with marginal placenta
- (d) United valvate sepals, free imbricate petals, free stamens, unilocular ovary with marginal placentation

Which of the following is not a flower

[KCET 1997; BVP 2002]

- (a) Rose
- (b) Lotus
- (c) Sunflower
- (d) Passion flower
- Adaptive heterophylly is found in 23.
- [MP PMT 2013]
- (a) Limnophila heterophylla (b) Alysicarpus heterophyllus
- (c) Eucalyptus
- (d) Jack fruit tree
- Inferior ovary occurs in 24.
- **ICPMT 19951**
- (a) Cruciferae
- (b) Compositae
- (c) Malvaceae
- (d) Ranunculaceae
- Which of the following are floral characters of Malvaceae 25.

[Kerala PMT 2007]

- (a) Pedicellate, bracteate, hermaphrodite, tetramerous, actinomorphic, complete and superior ovary
- (b) Compound spike, flowers bracteate, bracteolate, incomplete, bi or unisexual and hypogynous
- (c) Pedicellate, hermaphrodite, zygomorphic, complete and superior ovary
- (d) Head inflorescence, bracteate, hermaphrodite or unisexual, actinomorphic, or zygomorphic and inferior ovary
- (e) Jointed pedicel, bracteate, bracteolate, hermaphrodite, pentamerous, actinomorphic, complete and superior ovary

26. Coleoptile represents

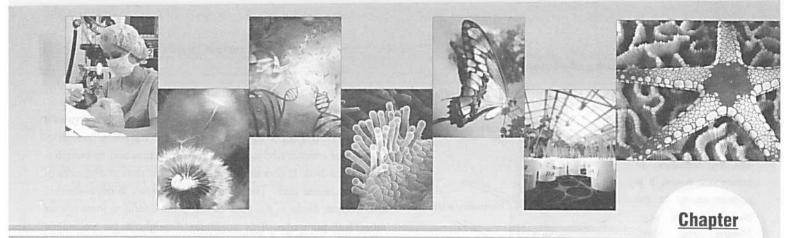

[NCERT: MP PMT 2013]

- (a) Covering of radical
- (b) Covering of cotyledon
- (c) Covering of plumule
- (d) Synonym of plumule

Answers and Solutions

26	C					THE REAL PROPERTY.			

- 1. (d) A plant which lives for a few days is called ephemeral because of a very short growing season. Such plant are found near deserts or in very cold countries. e.g., Arabidopsis species have life span of 20-28 days.
- (a) Lodicules are two scale like structures that lie at the 2. base of the ovary of a grass flower including jawar.
- (a) In heterostyly condition, stamens, style and stigma are of different heights, e.g., Primula, Oxalis, Linum etc.
- (b) Maize is a monocotyledonous plant where as China rose, Mango and Sunflower are dicotyledonous plants.
- 5. In Cruciferae.
 - Bicarpellary: Gynoecium consisting of two carpels fused laterally forming a compound pistil.
 - Parietal placentation: Ovary is bi to multicarpellary but unilocular.
 - Tetradynamous: There are six free stamens, inner four larger and outer two are small.
 - Siliqua fruit : Siliqua is a dry dehiscent fruit develop from bicarpellary, syncarpous and superior ovary.
- Raphanobrassica, Triticale and Bromato are some intergeneric hybrids. Raphanobrassica (Cabbage) is the result of distant cross between Raphanus (Radish) and Brassica (Cabbage).
- (c) Actinomorphic, bisexual, epicalyx 3 to 7, calyx 5 15. gamosepalous, corolla 5 polypetalous usually adnate at the base to the staminal tube, Androecium indefinite stamens, gynoecium pentacarpellary to indefinite. syncarpous, ovary superior.
- (d) In members of Cruciferae (Brassicaceae), secretory cells 17. are found which contains myrosin enzyme. This also accompanies the sulphur containing glucosides which hydrolyses them into glucose and isothiocynates (oil).
- 18. The apex form a tendril called tendrillar, e.g., Gloriosa.
- (c) Amorphophallus (simple spadix inflorescence) is largest 20. inflorescence which 5.5 m long.
- 22. (c) Sunflower (Helianthus annus) is a inflorescence (capitulum). It is a plant of family compositae (Asteraceae).
- 23. (a) Basal type of placentation, ovary is bicarpellary, syncarpous and unilocular and a single ovule is borne at the base of ovary, e.g., compositae (Marigold, sunflower). In family compositae carpels 2, connate, ovary inferior and basal placentation.

A group of cells performing a particular function is collectively called as tissue. A tissue may be defined as, "a group of similar or dissimilar cells having common origin and performing specific function".

Tissues are mainly divided into three categories: Meristematic tissues or Meristems, Permanent tissues and Secretory tissues

Meristematic tissues or Meristems

The word "Meristem" originated from "Meristos" (Greek = continuous division) and the term meristem was introduced by Nageli (1858). A group of cells which are much active and capable of showing continuous divisions and redivisions, is called as meristematic tissue. The various characteristic features of the meristems are discussed below:

- (1) They contain immature and young cells and are capable of repeated divisions.
 - (2) Intercellular spaces are not present in meristematic tissue.
 - (3) They contain a homogeneous thin cellulosic wall.
- (4) They contain large nuclei associated with abundant cytoplasm.
- (5) They are metabolically very active but they do not store food material and further no plastids in them.
 - (6) Vacuoles are small or absent.
 - (7) Meristematic cells are isodiametric in shape.
- (8) Undifferentiated tissue in which cells divides continuously $G_1 \xrightarrow{} S \rightarrow G_2 \xrightarrow{} M$.

Types of meristems

The meristems may be classified on the basis of their mode of origin, position or function :

According to origin and development : On the basis of origin, meristematic tissues are of three types :

- (1) **Promeristem or Primordial meristem:** The promeristem originates from embryo and therefore, called primordial or embryonic meristem. It is present in the regions where an organ or a part of plant body is initiated. A group of initial cells that lay down the foundation of an organ or a plant part, is called promeristem. It occupies a small area at the tips of stem and root. The promeristem gives rise to all other meristems including the primary meristem.
- (2) **Primary meristem :** A primary meristem originates from promeristem and retains its meristematic activity. It is located in the apices of roots, stems and the leaf primordia. Primary meristem gives rise to the primary permanent tissue.
- (3) **Secondary Meristem**: They always arise in permanent tissues and have no typical promeristem. Some living permanent cells may regain the meristematic nature. This process in which permanent tissue regains meristematic nature is called dedifferentiation. The secondary meristems are so called because they originate from permanent cells. The phellogen or cork cambium arising from epidermis, cortex or other cells during secondary growth, is an important example of secondary meristem. The secondary meristems produce secondary tissues in the plant body and add new cells for effective protection and repair.

According to position: On the basis of their position in the plant body meristems are classified into three categories:

(1) Apical meristem: This meristem is located at the growing apices of main and lateral shoots and roots. These cells are responsible for linear growth of an organ. Solitary apical cells occur in ferns and other Pteridophytes while apical initials are found in other vascular plants.

(2) Intercalary meristem: These are the portions of apical

meristems which are separated from the apex during the growth of axis and formation of permanent tissues. It is present mostly at the base of node (e.g., Mentha viridis, Mint), base of internode (e.g., stem of many monocots Wheat, Paddy, Grasses, Pteridophytes like Equisetum) or at the base of the leaf Pinus). The intercalary meristems

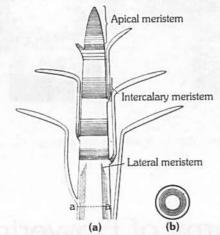

Fig: 2.2-1 Various meristematic tissue

intercalary meristems ultimately disappear and give rise to permanent tissues.

(3) Lateral meristem: These meristems occur laterally in the axis, parallel to the sides of stems and roots. This meristem consists of initials which divide mainly in one plane (periclinal) and results in increase in the diameter of an organ. The cambium of vascular bundles (Fascicular, interfascicular and extrastelar cambium) and the cork cambium or phellogen belongs to this category and are found in dicotyledons and gymnosperms.

According to function: Haberlandt in 1890 classified the primary meristem at the apex of stem under the following three types:

- (1) Protoderm: It is the outermost layer of the apical meristem which develops into the epidermis or epidermal tissue system.
- (2) Procambium: It occurs inside the protoderm. Some of the cells of young growing region which by their elongation and differentiation give rise to primary vascular tissue, constitute the procambium.
- (3) **Ground meristem:** It constitutes the major part of the apical meristem which develops ground tissues like hypodermis, cortex, endodermis, pericycle, pith and medullary rays.

According to plane of cell division: On the basis of their plane of cell division meristem are classified into three categories:

- (1) Mass meristem: The cells divide anticlinally in all planes, so mass of cells is formed. e.g., formation of spores, cortex, pith, endosperm.
- (2) Plate meristem: The cells divide anticlinally in two planes, so plate like area increased. e.g., formation of epidermis and lamina of leaves.
- (3) Rib or File meristem: The cells divide anticlinally in one plane, so row or column of cells is formed. e.g., formation of lateral root.

Structure and organisation of apical meristem

- (1) Vegetative shoot apex: Shoot apex was first recognized by Wolff (1759) shoot apex is derived from meristem present in plumule of embryo and occurs at the tip of stem and its branches as terminal bud. It also occurs in the inactive state in the axils of leaves as lateral buds. The tip of the shoot apex is dome-shaped and from its flanks at the base of the dome divide to form one or more leaf primordia. This continues throughout the vegetative phase. Many theories have been put forward to explain shoot apex, such as:
- (i) **Apical cell theory**: This theory was proposed by Nageli (1858). According to this theory, shoot apical meristem consists of single apical cell. This theory is applicable in case of higher algae, bryophytes and in many pteridophytes but not in higher plants (i.e., gymnosperms and angiosperms).
- (ii) Histogen theory: It was proposed by Hanstein (1870). According to this theory, the shoot apical meristem consists of three distinct meristematic zones or layers (or histogens).
- (a) Dermatogen: Outermost layer and it forms epidermis and epidermal tissue system.
- (b) Periblem: It is the middle layer which gives rise to cortex and endodermis.
 - (c) Plerome: The innermost layer forms pith and stele.
- (iii) Tunica corpus theory: This theory was proposed by Schmidt (1924). According to this theory, the shoot apex consists of two distinct zones.
- (a) Tunica: It is mostly single layered and forms epidermis. The cells of tunica are smaller than corpus. The tunica shows only anticlinal division and it is responsible for surface growth.

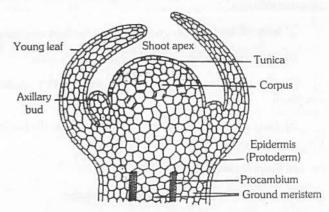

Fig: 2.2-2 L.S. Vegetative shoot apex

(b) Corpus: It represents the central core with larger cells. Corpus shows divisions in all planes and it is responsible for volume growth.

Popham and Chan (1950) introduced the term mantle for tunica and core for corpus.

- (2) Root apex: A group of initial cells, present at the subterminal region of the growing root tip, which is protected by a root cap, is called root apical meristem or root apex. It is embryonic in origin and formed from the radicle part of embryo. However, in adventitious roots it is produced from derivatives of root apex. According to Hanstein (1870) root apex of most of the dicotyledons also consists of three meristematic zones plerome, periblem and dermatogen (fourth meristem calyptrogen to form root cap only in monocots).
- (i) Dermatogen: It gives rise to epiblema or piliferous layer or rhizodermis.
 - (ii) Periblem: It gives rise to cortex including endodermis..
 - (iii) Plerome: It gives rise to vascular tissue including pith.

Regarding the apical organisation of root following theories have been put forward.

Korper-Kappe theory: It was proposed by Schuepp (1917). This theory is comparable with the tunica and corpus theory of shoot apex. Korper means body and Kappe means cap.

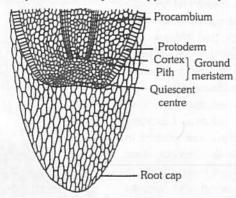

Fig: 2.2-3 L.S. Root apical meristem

Quiescent centre theory: It was proposed by Clowes (1961) in maize. According to him, in addition to actively dividing cells, a zone of inactive cells is present in the central part of the root apex called quiescent centre.

The cells in this region have light cytoplasm, small nuclei, lower concentration of DNA, RNA and protein.

(3) Reproductive apex: During reproductive phase, the

vegetative apices are converted into reproductive apices. Before conversion, the apex stops producing leaf primordia. The summit of the apex which remained inactive during the vegetative phase, starts dividing. As a result of cell divisions, the apical

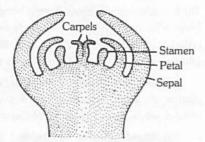

Fig: 2.2-4 L.S. Reproductive apex (diagrammatic)

meristem undergoes change in shape and increase in size. The apex may develop into a flower or an inflorescence.

Permanent tissues

Permanent tissues are made up of mature cells which have lost the capacity to divide and have attained a permanent shape, size and function due to division and differentiation in meristematic tissues. The cells of these tissues are either living or dead, thinwalled or thick-walled. Permanent tissues are of following types:

Simple permanent tissues

Simple tissues are a group of cells which are all alike in origin, form and function. They are further grouped under three categories:

(1) Parenchyma: Parenchyma is most simple and unspecialized tissue which is concerned mainly with the vegetative activities of the plant.

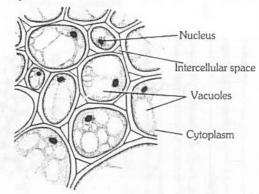

Fig: 2.2-5 Parenchyma in T.S.

The main characteristics of parenchyma cells are:

- (i) The cells are isodiametric, living, thin walled, soft, possess a distinct nucleus, having well developed intercellular spaces, vacuolated cytoplasm and cellulosic cell wall.
- (ii) The shape may be oval, spherical, cylindrical, rectangular and stellate (star shaped) in leaf petioles of banana and canna and some hydrophytes.
- (iii) This tissue is generally present in roots, stems, leaves, flowers, fruits and seeds.
- (iv) If they enclose large air spaces they are called as aerenchyma; if they develop chlorophyll, they are called as chlorenchyma and if they are elongated cells with tapering ends, they are called as prosenchyma.

Functions: They perform the following functions:

- (i) Storage of food materials. e.g., Carrot, Beetroot etc.
- (ii) Chlorenchyma helps in photosynthesis. Aerenchyma helps in floating of the aquatic plants (Hydrophytes) and also helps in gaseous exchange during respiration and photosynthesis. e.g., Hydrilla.
 - (iii) In turgid state they give rigidity to the plant organs.
- (iv) In emergency they behave like meristematic cells and help in healing of the various plant injuries.
- (v) Sometimes they store secretory substances (ergastic substance) such as tannins, resins and gums and they are called as idioblasts.

- (2) Collenchyma: The term collenchyma was coined by Schleiden (1839). It is the tissue of primary body. The main characteristics of collenchyma are given below:
- (i) The cells of this tissue contain protoplasm and are living without intercellular spaces. The cell walls are thickened at the corners and are made up of cellulose, hemicellulose and pectin.
- (ii) They are compactly arranged cells, oval, spherical or polygonal in outline. The tissue is elastic, extensible and have capacity to expand.
- (iii) Collenchyma occurs chiefly in the hypodermis of dicotyledonous stems (herbaceous, climbers or plants *e.g. Cucurbita*, *Helianthus*) and leaves. They are usually absent in monocots and in roots.

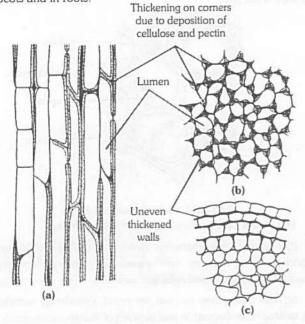

Fig: 2.2-6 (a) Collenchyma L.S. (b) and (c) T.S. of the same

Types of collenchyma: Majumdar (1941) divided collenchyma into three types on the basis of thickening:

- (i) **Angular collenchyma**: When the thickening of the cells is confined to the corners of the cells. *e.g.*, *Tagetes*, Tomato, *Datura*, Potato, etc.
- (ii) Plate or Lamellar collenchyma: When the thickenings are present in the tangential walls. e.g. hypodermis of sunflower stem.
- (iii) Lacunar or Tubular collenchyma: If the thickened cell wall is associated with intercellular spaces of the adjacent cells. e.g. leaf petioles of compositae (asteraceae) and malvaceae etc. hypodermis of Cucurbita stem, Salvia, Malva.

Functions

- (i) Provide mechanical support to petiole, pedicels, branches of stem, roots and fruits.
 - (ii) If they contain chlorophyll they help in photosynthesis.
- (iii) It is present at the margins of some leaves and resists tearing and bending effect of the wind.

(3) **Sclerenchyma :** It was discovered and coined by Mettenius (1805).

The main features of sclerenchyma are:

- (i) It consists of thick-walled dead cells.
- (ii) The cells vary in shape, size and origin.
- (iii) In the beginning the cells are living and have protoplasm but due to deposition of impermeable secondary walls (lignin) they become dead, thick and hard.

Types of sclerenchyma: They are of two types:

Sclerenchymatous These are greatly elongated and tapering at both the ends. The fully developed fibre cells are always dead. polygonal They are transverse section and walls are highly lignified. Intercellular spaces are absent and lumen is highly obliterated. The walls show simple and oblique pits. They provide mechanical strength to the plant. Some of the longest fibre yielding plants are Linum usitatissimum (Flax or Alsi), Corchorus, Cannabis, etc. The fibres are present in hypodermis of monocot stem, in pericycle of many dicots, in secondary wood and vascular bundle sheath in monocot stems. There are three different kinds of fibres:

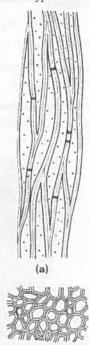

Fig: 2.2-7 Sclerenchymatous fibres (a) L.S. (b) T.S.

- (a) Bast fibres: The fibres present in the pericycle (e.g., Cannabis sativa / Hemp or Bhang), Linum usitatissimum and phloem (e.g., Corchorus capsularis (Jute), Hibiscus cannabinus (Patsan), Calotropis, Nerium, Sunn hemp etc.). These fibre are also known as extraxylary fibres.
- (b) Wood fibres: Those fibres which are associated with wood or xylem have bordered pits are known as wood fibres. Thick walled wood fibres having simple pits are called libriform fibres whereas thin walled wood fibres having bordered pits are called fibre-tracheids. A specific type of wood fibre is produced by Quercus rabra and is called gelatinous or mucilagenous fibres.
- (c) **Surface fibres**: The fibres present over surface of plant organs are called surface fibres. *e.g.*, Cotton fibres found in the testa of seeds, mesocarp fibres of Coconut (*Cocus nucifera*).
- (ii) Stone cells or Sclereids: They are lignified, extremely thick walled so that the lumen of the cells is almost obliterated and may be spherical, oval, cylindrical, T-shaped and even stellate. They are generally found in hard parts of the plant, e.g., endocarp of Walnut and Coconut. The sclereids provide mechanical support and hardness to the soft parts.

UNIVERSAL BOOK DEPOT 1960

Kind of sclereids: They are of five types:

- (a) **Brachysclereids or stone cells**: These are small and more or less isodiametric in shape. They occur in the cortex, pith, phloem, and pulp of fruits (e.g., Pyrus).
- (b) Macrosclereids or rod cells: These are rod-shaped elongated sclereids usually found in the leaves, cortex of stem and outer seed coats.

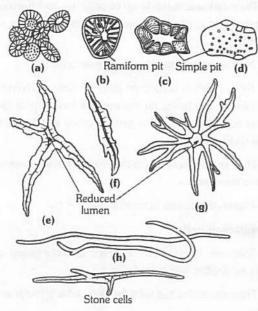

Fig: 2.2-8 Stone cells (a, b) from pulp of pear, (c, d) from stem cortex of Hoya, (e, f) from petiole of Camelia, (g) from stem cortex of Trochodendron, (h) from mesophyll cells of fig leaf

- (c) Osteosclereids or bone cells: These are bone or barrel-shaped sclereids dilated at their ends. e.g., leaf of Hakea.
- (d) Astrosclereids or stellate cells: These are star-shaped sclereids with extreme lobes or arms. e.g., leaf of Nymphaea.
- (e) Trichosclereids or internal hairs: These are hair-like sclereids found in the intercellular spaces in the leaves and stem of some hydrophytes.

Complex permanent tissues

A group of more than one type of cells having common origin and working together as a unit, is called complex permanent tissue. The important complex tissues in vascular plants are: xylem and phloem. Both these tissues are together called vascular tissue.

(1) **Xylem**: The term xylem was introduced by Nageli (1858). Xylem is a conducting tissue which conducts water and mineral nutrients upwards from the root to the leaves. It is also know as hadrome (Haberlandt).

On the basis of origin xylem is of two types:

- (i) Primary xylem: It is derived from procambium during primary growth. It consists of protoxylem and metaxylem.
- (ii) **Secondary xylem**: It is formed from vascular cambium during secondary growth.

Xylem is composed of four types of cells:

(i) **Tracheids**: Term "Tracheids" was given by Sanio (1863). The tracheids are elongated tubelike cells with tapering or rounded or oval ends with hard and lignified walls.

The cells are without protoplast and are dead on maturity. Tracheids possess bordered pits. Maximum bordered pits are formed in gymnospermous tracheids. They also possess various kinds of thickenings, e.g., annular, spiral, scalariform, reticulate or pitted tracheids. All the vascular plants have tracheids in their xylem. The main function of tracheids is to conduct water and minerals from the root to the leaf. They also provide strength and mechanical support to the plant.

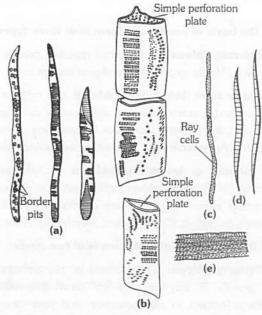

Fig: 2.2-9 Xylem-(a) Tracheids, (b) Tracheae, (c) and (e) Xylem parenchyma (d) Wood fibres (wood sclerenchyma)

- (ii) **Xylem vessels or Tracheae**: Vessels are rows of elongated tube-like cells, placed end to end with their end walls dissolved. Vessels are multicellular with wide lumen. The vessels may be annular, spiral, scalariform, reticulate or pitted. Vessels are absent in pteridophytes and gymnosperms (except Ephedra, Gnetum, Selaginella, Pteridium). In angiosperms (porous wood) vessels are always present (Vessels are absent in family Winteraceae, Trochodendraceae and Tepacenpaceae of Angiosperm i.e. Lotus, Wintera, Trochodendron). It also provide mechanical support to the plant and help in conduction. On the basis of distribution and size of vessels, porous wood is of two types:
- (a) **Diffuse porous wood (Primitive)**: Vessels of same size are uniformly distributed throughout the growth or annual ring e.g., Pyrus, Azadirachta, Eucalyptus, Mangifera sp., Betula. They are characteristics of plants growing in tropical region.
- (b) Ring porous wood (Advanced): Large vessels are formed in early wood when the need of water is great and small vessels are formed in late wood e.g. Quercus, Morus, Cassia, Delbergia, Tilea sp.

- (iii) **Wood (xylem) parenchyma :** These are the living parenchymatous cells. As found associated with xylem they are known as wood parenchyma. They serve for the storage of reserve food and also help in conduction of water upwards through tracheids and vessels.
- (iv) Wood (xylem) fibres: The long, slender, pointed, dead and sclerenchymatous cells found associated with xylem are termed wood fibres. They aid the mechanical strength of xylem and various organs of plant body.
- (2) Phloem (bast): Term "Phloem" was given by Nageli. Its main function is the transport of organic food materials from leaves to stem and roots in a downward direction. It is also known as leptome.

On the basis of position phloem is of three types:

- (i) External phloem: It is normal type and present outside the xylem e.g., Mostly angiosperms and gymnosperms.
- (ii) Internal or Intraxylary phloem: It originates from procambium and is primary phloem which occurs on innerside of primary xylem. It is primary anomalous structure. e.g., Members of Apocynaceae, Asclepiadaceae, Convolvulaceae, Solanaceae.
- (iii) Induced or Interxylary phloem: It originates from cambium and is secondary phloem which occurs in groups within the secondary xylem. It is secondary anomalous structure. e.g., Leptadaenia, Salvadora, Chenopodium, Boerhaavia, Amaranthus.

On the basis of origin, phloem is of two types:

(i) **Primary phloem**: It is formed by procambium during primary growth. It may or may not show differentiation in protophloem (consists of sieve elements and parenchyma) and metaphloem (develop after protophloem and consists of sieve elements, parenchyma and fibre).

During the primary growth the protophloem elements are crushed by the surrounding tissues and disappear. This process is known as obliteration.

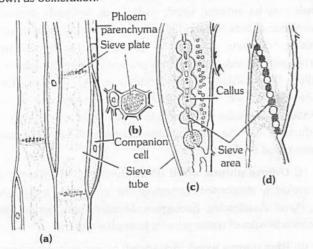

Fig: 2.2-10 Parts of Phloem (a) L.S. of phloem tissue, (b) T.S. of phloem tissue, (c) Sieve tubes of Vitis, (d) L.S. of sieve plate

(ii) Secondary phloem: It is produced during secondary growth by vascular cambium.

It consists of the following elements:

Sieve element

- (i) They are long tube-like cells placed end to end, forming a continuous channel in the plant parts.
- (ii) Their cell wall is made up of cellulose and transverse wall is perforated like a normal sieve and hence they are called as sieve tubes.
 - (iii) Nucleus is not found in the mature cells.
- (iv) Sieve pores in winter get plugged with a substance called callose (soluble) and hence the transport of food is retarded. But in spring and summer, this callose gets dissolved and hence transport of food is rapid again.
- (v) Their main function is to translocate the food material from one part to the other.
 - (vi) P-protein is found in sieve tubes.

Companion cells

- (i) They are thin-walled, more or less elongated cells and which are associated with sieve tubes.
 - (ii) They are connected with the sieve tube through sieve pore.
 - (iii) They contain nucleus and are therefore, living in nature.
- (iv) They are not found in pteridophytes and gymnosperms but are always present in angiosperms.

Phloem parenchyma: The parenchyma associated with the phloem is called phloem parenchyma. The cells are elongated with rounded ends and possess cellulosic cell walls. These cells are living and store food reserves in the form of starch and fats. They are present in pteridophytes and most of dicotyledonous angiosperms. They are absent in monocots and few dicots like *Ranunculus*.

Phloem or Bast fibres : The sclerenchymatous fibres associated with the phloem are called as phloem fibres or bast fibres. The fibres are elongated lignified sclerenchymatous cells with tapering ends and with simple pits. They are non-living cells that provide mechanical support to the organs. Commercial jute fibres are obtained from phloem fibres.

Special or Secretory tissues

These tissue perform special function in plants, e.g., secretion of resins gum, oil and latex.

These tissues are of two types:

(1) Laticiferous tissues: They are made up of thin walled, elongated, branched and multinucleate (coenocytic) structures that contain colourless, milky or yellow coloured juice called latex. These occur irregularly distributed in the mass of parenchymatous cells. Latex is contained inside the laticiferous tissue which is of two types:

- (i) Latex cells: A laticiferous cell is a highly branched cell with long slender processes ramifying in all directions in the ground tissue of the organ. They do not fuse and do not form network. Plants having such tissues are called simple or non-articulated laticifers. e.g., Calotropis (Asclepiadaceae) Nerium, Vinca (Apocyanaceae), Euphorbia (Euphorbiaceae), Ficus (Moraceae).
- (ii) Latex vessels: They are formed due to fusion of cells and form network like structure in all directions. At maturity, they form a highly ramifying system of channels full of latex inside the organ. Plants having such tissues are called compound or articulated laticifers. e.g., Argemone, Papaver (Papaveraceae), Sonchus (Compositae), Hevea, Manihot (Euphorbiaceae).
- (2) Glandular tissue: This is a highly specialized tissue consisting of glands, discharging diverse functions, including secretory and excretory. Glands may be external or internal.
- (i) External glands: They generally occur on the epidermis of stem and leaves as glandular hair in *Plumbago* and *Boerhaavia*, stinging hair secrete poisonous substance in *Urtica dioica*, nectar secreting glands in flowers or leaves. *e.g.*, Rutaceae and Euphorbiaceae. Digestive enzyme secreting glands in insectivorous plants *e.g.*, *Drosera* (Sundew), *Nepenthes* (Pitcher plant).
- (ii) Internal glands: These are present internally and are of several types e.g., oil glands in Citrus and Eucalyptus, resinous ducts in Pinus, these resin canals are schizogenous in nature. mucilage canals in Cycas. Water secreting glands (hydathodes) in Colocasia (present at the tip of leaves), Tropaeoleum (along margin), etc. The glands which secrete essential oil are called osmophores (osmotrophs).

The tissue system

Several tissues may collectively perform the same function. A collection of tissues performing the same general function is known as a "Tissue System". According to Sachs (1975) there are three major tissue systems in plants as follows:

(1) Epidermal tissue system: The tissues of this system originate from the outermost layer of apical meristem. It forms the outermost covering of various plant organs which remains in direct contact with the environment.

Epidermis : Epidermis is composed of single layer of cells. These cells vary in their shape and size and form a continuous layer interrupted by stomata. In some cases epidermis may be multilayered e.g. Ficus, Nerium, Peperomia, Begonia etc.

The epidermal cells are living, parenchymatous, and compactly arranged without intercellular spaces.

Certain epidermal cells of some plants or plant parts are differentiated into variety of cell types :

- (i) In aerial roots, the multiple epidermal cells are modified to velamen, which absorbs water from the atmosphere (e.g., Orchids).
- (ii) Some of the cells in the leaves of grasses are comparatively very large, called bulliform or motor cells. It is hygroscopic in nature. e.g., Ammophila. They are thin-walled and contain big central vacuoles filled with water. They play an important role in the folding and unfolding of leaves.

(iii) Some members of Gramineae and Cyperaceae possess two types of epidermal cells: the long cells and the short cells. The short cells may be cork cells or silica cells.

Cuticle and Wax: In aerial parts, epidermis is covered by cuticle. The epidermal cells secrete a waxy substance called cutin, which forms a layer of variable thickness (the cuticle) within and on the outer surface of its all walls. It helps in reducing the loss of water by evaporation. Usually the cuticle is covered with wax which may be deposited in the form of granules, rods, crusts or viscous semiliquid masses. Other substances deposited on the cuticle surface may be oil, resin, silicon and salts (cystoliths are crystals of calcium carbonate, e.g., Ficus. Druse and Raphides, e.g., Pistia are crystals of calcium oxalate). Thick cuticle are found in leaves of dry habitats plants.

Stomata: Stomata are minute apertures in the epidermis. Each aperture is bounded by two kidney shaped cells, called guard cells. Stomata are absent in roots. In xerophytes the stomata are sunken in grooves due to which rate of transpiration is greatly reduced (e.g. Nerium). Usually there is a large air cavity below each aperture, it is called substomatal cavity. In some species the guard cells are surrounded by subsidiary cells or accessory cells which differ morphologically as well as ontogenitally from the other epidermal cells. In monocots subsidiary cells and guard cells originated from same cell. e.g., Doob, Maize guard cells are dumb bell shape. Stomata are scattered in dicot leaves but they are arranged in rows in monocots.

Trichomes: These are epidermal outgrowths present temporarily or permanently on almost all plant parts. They may be unicellular or multicellular and vary in size and shape in different species. They may be of different types: stellate hair, glandular hair, short glandular hair, floccose hair, urticating hair and stinging hair. The trichomes serve for checking excess loss of water and for protection.

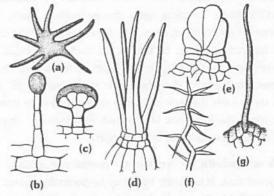

Fig: 2.2-11 Appendages of epidermis of leaves
(a) Stellate hair of Alyssum, (b) Glandular hair of
Pelorgonium (c) Short glandular hair of lavandula, (d)
Floccose hair of Malva, (e) Glandular hair of Solanum,
(f) Urticating hair of Verbascum, (g) Stinging hair of Cestus

Root hairs: They are enlargements of special epiblema cells called trichoblasts and occur in a particular zone of young root called root hair zone. A root hair cell has vacuolated protoplast with nucleus present towards the apical part of hair. They are specialised to absorb water from soil crevices. They also hold soil particles.

(2) **Ground or Fundamental tissue system :** Ground tissue system includes all the tissues of plant body except epidermal tissue system and vascular tissues. It forms the bulk of body. This tissue system mainly originates from ground meristem. The ground tissues constitute the following parts :

Cortex: It lies between epidermis and the pericycle. The cortex is distinct in dicotyledons but not in monocotyledons where there is no clear demarcation between cortex and pith. It is further differentiated into:

Hypodermis: It is collenchymatous in dicot stem and sclerenchymatous in monocot stem. It provides strength.

General cortex: It consists of parenchymatous cells. Its main function is storage of food.

Endodermis (Starch sheath): It is mostly single layered and is made up of parenchymatous barrel shaped compactly arranged cells. The inner and radial or transverse wall of endodermal cells have casparian strips of suberin. In roots thick walled endodermal cells are interrupted by thin walled cells just outside the protoxylem patches. These thin walled endodermal cells are called passage cells or transfusion cells. A fully developed endodermis is found in all types of roots. Endodermis with characteristic casparian bands is absent in woody dicot stem, monocot stem and leaves of angiosperms.

Endodermis behaves as water tight dam to check the loss of water and air dam to check the entry of air in xylem elements. Endodermis is internal protective tissue.

Pericycle: It is a single layered or multilayered cylinder of thin-walled or thick-walled cells present between the endodermis and vascular tissues. In some cases, the pericycle is made up of many layers of sclerenchymatous cells (*Cucurbita* stem) or in the form of alternating bands of thin-walled and thick-walled cells (Sunflower stem). In case of roots, the pericycle is made up of thin-walled parenchymatous cells which later on gives rise to lateral roots. In dicot roots the cork cambium originates in the pericycle which results in the formation of periderm. Pericycle also gives rise to a part of vascular cambium in dicot roots.

Pith or Medulla: It occupies the central part in dicot stem, and monocot root. It is mostly made up of parenchymatous cells. In dicot root pith is completely obliterated by the metaxylem elements. In dicot stem the pith cells between the vascular bundles become radially elongated and known as primary medullary rays or pith rays. They help in lateral translocation.

(3) Vascular tissue system: The central cylinder of the shoot or root surrounded by cortex is called stele. The varying number of vascular bundles formed inside the stele constitute vascular tissue system. Xylem, phloem and cambium are the major parts of the vascular bundle. Vascular bundle may be of following types: Radial: The xylem and phloem strands alternate with each other separated by parenchymatous cells. Such kinds of vascular bundles are called radial and found mainly in roots.

Conjoint: A vascular bundle having both xylem and phloem together, is called conjoint. Normally the xylem and phloem occur in the same radius. They occur in stems.

Collateral: A vascular bundle in which the phloem lies towards outer side and xylem towards inner side, is called collateral, e.g., Sunflower.

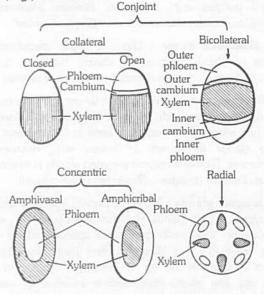

Fig: 2.2-12 Different types of vascular bundles

Collateral bundle having a cambium between xylem and phloem is said to be of the open type, e.g., Dicot stem.

Collateral bundle lacking a cambium between xylem and phloem is said to be of the closed type, e.g., Monocot stem.

Bicollateral: A vascular bundle having the phloem strands on both outer and inner side of xylem, is called bicollateral. e.g., *Cucurbita*, *Lagenaria*. Bicollateral vascular bundles are found in family Cucurbitaceae, Solanaceae and Myrtaceae.

Concentric: A vascular bundle in which one tissue is completely surrounded by the other, is called concentric. The concentric bundles are of two types:

- (i) Amphivasal (Leptocentric): The phloem lies in the centre and remains completely surrounded by xylem. e.g., Dracaena, Yucca.
- (ii) Amphicribal (Hadrocentric): The xylem lies in the centre and remains completely surrounded by phloem. e.g., Ferns.

Stelar system

Stelar theory was proposed by Van Tieghem and Douliot (1886). According to this concept primary body of root and stem are basically alike anatomically *i.e.* each consists of a central stele surrounded by cortex. Stele includes the vascular tissues and the ground tissue like pericycle and pith, when present.

UNIVERSAL BOOK DEPOT 1960

Table: 2.2-1 The types of steles are				
Types of stele	Diagrammatic representation			
(1) Protostele: This term was given by Jeffrey. It is the simplest and most primitive type of stele in which central core of xylem surround by phloem.				
(i) Haplostele: It consists of a smooth core of xylem which is surrounded by a ring of phloem. e.g., Rhynia, Selaginella, Lycopodium, etc.	Endodermis Pericycle Phloem Xylem Leaf trace			
(ii) Actinostele: Protostele having star shaped xylem core with many radiating arms called actinostele. e.g. Psilotum, Lycopodium etc.	Phloem Endodermis Xylem Leaf trace			
(iii) Plectostele: A protostele in which xylem core broken into a number of parallel plates is known as plectostele. e.g., Lycopodium clavatum.	Phloem Xylem Leaf trace			
(iv) Mixed protostele: A protostele in which xylem is broken into small group or patches is known as mixed protostele. e.g., Lycopodium cemuum, Hymenophyllum demissum, etc.	Endodermis Parenchyma Pericycle Xylem Phloem			
(2) Siphonostele: A protostele with central pith is called siphonostele or medullated stele. It is considered to be derived phylogenetically from protostele and thus represents an advance form. It is of two types:				
(i) Ectophloic siphonostele: When phloem occurs on the outer side of xylem. e.g., Osmunda, Equisetum.	Endodermis Leaf trace Pith			
(ii) Amphiphloic siphonostele: When phloem is present on both external and internal sides of the xylem. e.g., Marsilea, Adiantum.	Outer phloem endodermis Xylem Pith Inner phloem Inner endodermis			

Modification of	
siphonostele : A siphonostele with non- overlapping leaf gaps is known as solenostele. It may be ectophloic or amphiphloic.	Phloem Leaf gap Pith Leaf trace Inner phloem Leaf gap Leaf trace Pith Outer endodermis Inner phloem endodermis
(ii) Dictyostele: A siphonostele with overlapping leaf gaps is known as dictyostele. It has many scattered vascular strands called as meristeles. e.g., Dryopteris, Pteris Ophioglossum.	Meristeles Leaf trace
(iii) Polycyclic stele: When vascular tissue is present in the form of two or more concentric cylinders. e.g., Pteridium aquilinum, Marattia. It may be polycyclic solenostele or polycyclic dictyostele.	Leaf gap Solenostelic cylinder Leaf trace Siphonostelic cylinder
(iv) Polysteles: Sometimes more than one steles are present in the axis of some pteridophytes. e.g., 2 steles in Selaginella kraussiana, 16 steles in S. laevigata.	steles

Internal structure of root, stem and leaf

Table: 2.2-2 Functions of different organs and tissues of a plant tissue system

	Roots	Stems	Leaves
(i) Functions	(i) Absorb water and minerals.	(i) Transport water and nutrients.	Carry on photosynthesis.
	(ii) Anchor plant.	(ii) Support leaves.	
	(iii) Store materials.	(iii) Help to store materials.	

(ii) Tissues			
(a) Epidermis	Root hairs absorb water and minerals.	Protect inner tissues.	Stomata carry on gas exchange.
(b) Cortex	Store products of photosynth- esis and water.	Carry on photosynthesis if green.	
(c) Endodermis	Regulates passage of minerals into vascular cylinder.	Regulates passage of minerals also into vascular tissue, if present.	Regulates passage of minerals into vascular tissue if present.
(d) Vascular bundle	Transport water and nutrients.	Transport water and nutrients.	Transport water and nutrients.
(e) Pith	Store products of photosynth- esis and water.	Store products of photosynthesis.	
(f) Mesophyll (i) Spongy layer (ii) Palisade layer			Carry on gaseous exchange and photosynthesis.

Table: 2.2-3

Difference between internal structure of root and stem

Description	Root	Stem	
(i) Epidermis or Epiblema	Epiblema or piliferous layer without cuticle.	Epidermis usually with cuticle.	
(ii) Epidermal Hairs	Unicellular.	Usually multicellular.	
(ii) Hypodermis	Absent	Present – Collenchymatous or sclerenchymatous.	

(iv) Chlorenchyma in cortex	Absent.	Usually present in young stems but absent in old stem.
(v) Endodermis	Very distinct.	Poorly developed or absent.
(vi) Vascular bundle	Radial.	Conjoint collateral or bicollateral or concentric.
(vii) Xylem	Exarch.	Endarch.

Origin of Lateral roots: Lateral roots arise endogenously *i.e.*, form the cells inside the endodermis. They arise from pericycle cells.

Table: 2.2-4 Difference between dicot and monocot leaf

Character	Dicot leaf	Monocot leaf Isobilateral	
(i) Type of leaf	Dorsiventral (bifacial).		
(ii) Stomata	Usually more on lower epidermis.	Equal on lower and upper epidermis (amphistomatic).	
(iii) Mesophyll	Made up of two types of tissues (a) Palisade parenchyma. (b) Spongy parenchyma with large intercellular spaces.	Only spongy parenchyma is present which has very small intercellular spaces.	
(iv) Bundle sheath	Made up of parenchyma. Just above and below the vascular bundle some parenchymatous cells or collenchymatous cells are present (upto epidermis).	Made up of parenchyma but just above and below the vascular bundles are found sclerenchymatous cells (upto epidermis)	
(v) Bulliform or motor cells	Absent.	Present on uppe epidermis.	

Kranz type anatomy occurs in both monocot and dicot leaves of some tropical and arid areas. Kranz anatomy is characteristic feature of C_4 plants. The mesophyll is undifferentiated and occurs in concentric layers around vascular bundles. Cells of bundle sheath possess large chloroplast.

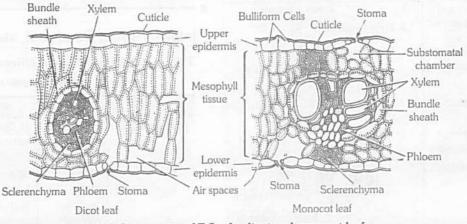

Fig: 2.2-13 Comparison of T.S. of a dicot and monocot leaf

Table: 2.2-5 Difference between dicot and monocot stem

Characters	Monocotyledonous Stem	Dicotyledonous Stem		
(i) Epidermis	Present, cells comparatively smaller and without hair.	Present, cells larger and with hair.		
(ii) Hypodermis	Sclerenchymatous (non-green)	Collenchymatous (green).		
(iii) Cortex	Absent, but ground tissue is present from hypodermis to the centre of stem.	Made up of several layers of parenchymatous tissue.		
(iv) Endodermis	Absent	One layered, starchy sheath which is usually not well differentiated.		
(v) Pericycle	Absent	Made up of 1 or more layers of parenchymatous and sclerenchymatous cells.		
(vi) Medullary rays	Absent	Found in between vascular bundles.		
(vii) Pith (Medulla)	Absent	Abundant, made up of parenchymatous cells situated in the centre of stem.		
(viii) Vascular	Scattered	Vascular bundles in a ring		
bundles	Conjoint, Collateral and closed.	Conjoint, collateral and open.		
	Larger towards centre.	All of same size.		
	Oval	Usually wedge-shaped.		
	Bundle sheath present.	Bundle sheath absent.		
	Phloem parenchyma absent.	Phloem parenchyma present.		
	Xylem vessels either Y or V shaped.	Xylem vessels more radial.		

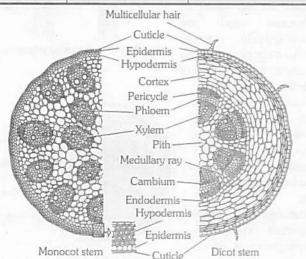

Fig: 2.2-14 Comparision of the T.S. of monocot and dicot stem

Table: 2.2-6 Difference between dicot and monocot root

Character	Dicot Root	Monocot Root	
(i) Pericycle	Gives rise to secondary roots and lateral meristem	Gives rise to lateral roots only Hexarch to polyarch (It is more than 6 in number)	
(ii) Vascular bundles	Diarch to hexarch		
(iii) Cambium	Develops at the time of secondary growth	Absent	
(iv) Pith	Absent or poorly developed	Abundant and fully developed	
(v) Secondary growth	Takes place	Does not take place	
(vi) Cortex and Endodermis	Narrow cortex. Endodermis is less thickened and casparian strips are more prominent	Cortex wide. Casparian strips are visible only in young root. Later on endodermal cells become highly thickened	

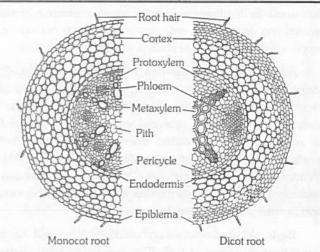

Fig: 2.2-15 Comparision of the T.S. of monocot and dicot root

Secondary growth

The increase in thickness or girth due to the activity of the cambium and the cork cambium is known as secondary growth.

(1) **Secondary growth in stem :** On the basis of the activities of cambium and cork-cambium, secondary growth in stem can be discussed under the following heads :

Activity of cambium: The vascular cambium in between xylem and phloem is called intrafascicular or fascicular cambium which is primary in origin. At the time of secondary growth the parenchymatous cells of medullary rays between the vascular bundles become meristematic and form strip of cambium called as interfascicular cambium which is secondary in origin. Both inter and intrafascicular cambium joins together and form cambium ring which is partly primary and partly secondary in origin. By anticlinal divisions the circumference of the cambium increase. By periclinal division cambium produces the secondary xylem and phloem tissues on innerside and outerside. The amount of sec. xylem produced is 8-10 times greater than sec. phloem. Cambium cells are rectangular, thin walled, full of protoplasm and having meristematic activity. The cambium has two types of cells:

UNIVERSAL BOOK DEPOT 1960

390 Anatomy of Flowering Plants

The fusiform initials: Which are elongated and form fibres, sieve cells, sieve tubes, tracheids.

Ray initials: Which produce parenchyma cells of the rays in wood and phloem. Certain cells of cambium form some narrow bands of living parenchyma cells passing through secondary xylem and secondary phloem and are called secondary medullary rays. These provide radial conduction of food from the phloem, and water and mineral salts from the xylem.

Annual rings: Activity of cambium is not uniform in those plants which grow in the regions where favourable climatic conditions (spring or rainy season) alternate regularly with unfavourable climatic conditions (cold water or dry hot summer). In temperate climates, cambium becomes more active in spring and forms greater number of vessels with wider cavities; while in winter it becomes less active and forms narrower and smaller vessels. The wood formed in the spring is known as spring wood and that formed in the dry summer or cold winter autumn wood or late wood. Both autumn and spring wood constitute a growth or annual ring. In one year only one growth ring is formed. Spring wood is light in colour while autumn wood is dark in colour.

Activity of cork cambium: Cork cambium or phellogen develops from outer layer of cortex. It produces secondary cortex or phelloderm on innerside and cork or phellem on outerside. The cells of phellem are dead, suberized and impervious to water. Cells of phelloderm are thin walled, living and store food. Phellem, phellogen and phelloderm are collectively called as periderm. Periderm is secondary protective tissue. Due to pressure of secondary xylem, epidermis ruptures and cortex is largely lost after two or three years of secondary growth.

Bark: All dead tissues lying outside the active cork-cambium are collectively known as bark. This includes ruptured epidermis, hypodermis and cork. When cork-cambium appears in the form of a complete ring, it is known as ring bark, e.g., Betula (Bhojpatra). If the cork cambium occurs as separate strips and the resulting bark appears in the form of scales, such a bark is known as scaly bark. e.g., Eucalyptus, Psidium guava. The outermost layer of bark is dead and called as rhytidome.

Lenticels: These are aerating pores formed in the cork through which gaseous exchange takes place. They are formed as a result of the action of phellogen. A lenticel appears as a scar or protrusion on the surface of the stem and consists of a radial row of thin-walled cells, known as complementary cells or filling tissue. They are found in old dicot stem, main function is gas exchange.

Cork: It consists of dead cells with thick walls heavily impregnated with suberin. These cells are compactly arranged in radial rows without intercellular spaces. Cork is impervious to water and prevents its loss from the plant surface. It also protects the inner tissues from the attack of fungi and insects. There is no differentiation of bark, sap wood and heart wood of Date palm. Commercial cork is obtained from Quercus suber (Oak).

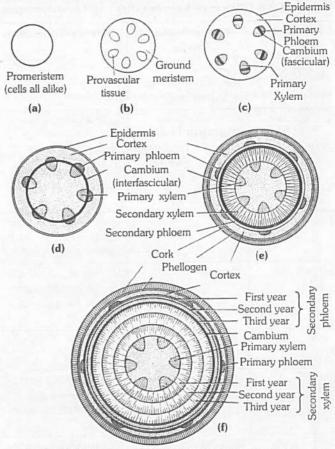

Fig: 2.2-16 Stages of secondary growth in stem

Heart wood and sap wood: In old trees, secondary wood

differentiated into a centrally situated darker and harder wood called heart wood the OT which duramen are physiologically inactive dead)and (almost outer light coloured zone called the sap wood or which alburnum are physiologically active. Dark colour of heart wood is due to the deposition of tannins, resins, gums, essential oils, etc. in the cell walls and cavities. The water conduction takes place sap wood. through During the conversion of into sap wood the most heartwood important change is development of tyloses in the heart Tyloses are balloon like

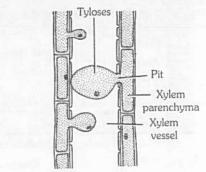

Fig: 2.2-17 Tyloses in xylem vessels

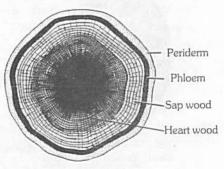

Fig: 2.2-18 T.S. of old dicot stem showing heart wood and sap wood

UNIVERSAL BOOK DEPOT 1960

structures, develop from xylem parenchyma. These tyloses block the passage of xylem vessels so also called as tracheal plug. The heart wood is commercially used as wood. When the plant is made hollow, it will not die because the water conduction takes place through sap wood. The heart wood is well developed in *Morus alba* (Mulberry). The heart wood is absent in *Populus* and *Salix* plant. As a tree grows older thickness of heartwood increases and sap wood remains same.

(2) Secondary growth in dicot roots: Vascular bundles in dicot roots are radial, exarch and mostly triarch. Vascular cambium is formed secondarily from conjunctive parenchyma cells lying just below each phloem strand. Thus the number of cambium strips form equal the number of phloem strands. The cells of pericycle lying outside the protoxylem also become meristematic to form part of strips of cambium. These cambial strips join the first formed cambium strips to form complete but wavy ring of vascular cambium. This cambium ring produces secondary xylem on inner side and secondary phloem on outer side. In roots, the growth rings are not distinct because there is no seasonal variation under the soil. From the outer layers of pericycle arises the phellogen which cuts phellem (cork) on the outer side and secondary cortex or phelloderm toward the inner side.

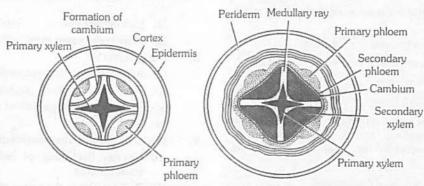

Fig: 2.2-19 Secondary growth in dicot

Tips & Tricks

- N.Grew is the father of anatomy (1682) and coined the term tissue and parenchyma.
- ** Haberlandt (1914) gave the terms Leptome for soft walled conducting part of phloem and hadrome for conducting part (tracheary elements) of xylem.
- In sugarcane there is no distinction of tunica and corpus.
- ✓ In the roots the meristem is subterminal due to the presence of terminal cap.
- Reproductive apex is elongated in Sagittaria but it can be 400 times broad in Chrysanthemum.
- Sieve cells or sieve tube elements resemble RBCs in being without nucleus in the mature state.
- The wood of Tectona grandis is termite resistant.
- Cavities are of three types:
 - Schizogenous: They are formed by enlargement of intercellular spaces or separation of cells e.g., oil cavities of Sunflower.
 - (2) Lysigenous: They are formed by degeneration of cells, e.g., oil cavity of Citrus and protoxylem lacunae or water cavity in monocot stem vascular bundles.
 - (3) Schizolysigenous: They are formed partly by separation and partly by degeneration of cells. e.g., protoxylem cavity.

- Pith cavity often present in monocot stems (e.g., grass) and occassionally in dicot stems (e.g., Ricinus).
- Wood without vessels is called homoxylous, e.g., Ranales (winteraceae, tetracentraceae, trochodendraceae). Whereas with vessels is called heteroxylous.
- The bottle cork is prepared from cork of Quercus suber (Oak tree).
- Lightest wood is of Ochroma pyramidate (O.lagopus).
- Heaviest wood is of Guaiacum officinale. In India heaviest wood is of Acacia sundra.
- Most durable soft wood is of Cedrus deodara.
- Reaction wood is a wood formed in bending stems. When reaction wood is formed on the lower side, it is called as Compression wood e.g., conifers. When it is formed on the upper side, it is called as tension wood e.g., Dicots.
- Mound periderm is similar to natural periderm. But it is restricted to the place of injury and is used in producing the commercial cork.
- Maceration is a method of separation of various tissues by disintegration of middle lamella.
- In some plants primary structure is abnormal such as presence of medullary bundles in pith e.g., Boerhaavia, Mirabilis, Achyranthes, Bougainvillea or presence of cortical vascular bundles (inverted) e.g., Casuarina and Nyctanthus.
- A protective tissue found in roots of some plants (Rosaceae, Myrtaceae) having alternate layers of endodermal and parenchyma cells are called periderm.
- Knots are the bases, scars/wounds of fallen branches which get covered by growth of secondary tissues. They form knots in the wood.

392 Internal Structure of Angiospermous Plants

- Abscission layer is a special layer of parenchymatous cells, appears at the base. Abscission is premature fall of plant parts from the plant without causing the injury. A protective layer of suberised thick walled cork cells is formed below the abscission layer to prevent infection or dessication (sometimes it is corky layer).
- Metaxylem consists of two larger and rounded vessels situated on the sides with the pitted tracheids in between them.
- Protoxylem consists of two smaller vessels situated towards the centre. The vessels of metaxylem are pitted and those of protoxylem are annular and spiral.
- Depending upon the relative position of protoxylem; xylem is of four types:
 - Exarch: Protoxylem towards the outerside.
 - (2) Endarch : Protoxylem towards innerside of metaxylem.
 - (3) Mesarch: Protoxylem surrounded by metaxylem.
 - (4) Centrach: Protoxylem in the centre of metaxylem.
- Endarch xylem is also called centrifugal as xylem matures from inside to outside. Similarly, exarch xylem is known as centripetal because differentiation of xylem proceeds from outside to inside e.g. roots.
- Root hairs are found in zone of maturation.
- In the leaf, vascular bundles are found in the veins.
- An example of monocots showing secondary growth in stems is Yucca or Draceana.
- Safranine stains lignified elements of the tissue.
- The longitudinal section of a root have four zones which occur in the following order (from the tip upward): Root cap, cell division, cell enlargement, cell maturation.
- Sequence of secondary tissues from outside : Cork → Cork cambium → Secondary cortex → Primary phloem → Older secondary phloem → Younger secondary phloem → Cambium → Younger secondary xylem → Older secondary xylem → Primary xylem → Pith.

Tissue (General)

- A group of cells alike in form, function and origin is called [NCERT; CMC Vellore 1994; MP PMT 1999]
 - (a) Organ
- (b) Organella

28.	Tunica corpus theory is related with [Odisha JEE 2009]		(c) Special epidermal hairs covering stomata in xerophytes
	(a) Root apex		
	(b) Lateral meristems (c) Root cap		(d) Callus secretion on sieve plates
	(d) Shoot apex (apical meristem)	41.	Plant tissues, which are actively growing have water content
29.	The baloon like outgrowth of parenchyma in the lumen of a		of
	vessel is known as [BHU 1994; NEET (Phase-II) 2016]		(a) 40 – 50% (b) 65 – 75%
	(a) Histogen (b) Tyloses		(c) 20 – 40% (d) 85 – 95%
	(c) Phellogen (d) Tunica	42.	A component of xylem is [MP PMT 1999]
30.	Vessels differ from tracheids [MHCET 2011]		(a) Sieve tube (b) Medullary ray
	(a) In being derived from single cell(b) In having vertical rows of cells with dissolved cross walls		(c) Sclereids (d) Tracheid
	(c) In being living	43.	Which of the following supporting tissues have cells with
	(d) They help in the conduction of water		unequally thickened walls
31.	Vascular cambium and cork cambium are examples of		(a) Fibres (b) Sclereids
	[CBSE PMT 1990; AIIMS 1999;		(c) Collenchyma (d) All the above
	J & K CET 2002; KCET 2009]	44.	
	(a) Lateral meristem (b) Apical meristem	-2-2.	tube elements is [CBSE PMT 2006]
	(c) Elements of xylem and phloem		(a) Presence of p-protein (b) Enucleate condition
	(d) Intercalary meristem		
32.	Laticiferous vessels instead of laticiferous cells are found in		
	(a) Ficus (b) Calotropis	45.	
	(c) Poppy (d) Nerium		(a) Teak wood (b) Shisham wood
33.	The histogen layer present at the apex of the root tip is called [BHU 2008]		(c) Chir wood (d) Sal wood
	cuircu	46.	All the following statements regarding sieve tube elements
	(a) Dermatogen (b) Procambium (c) Calyptrogen (d) Plerome		are true except [Kerala PMT 2007]
34.	Radial conduction of water takes place by [AMU (Med.) 2012]		(a) Their end walls have perforated sieve plates which
	(a) Vessels (b) Vessels and trachieds		become impregnated with lignin at maturity
	(c) Phloem (d) Ray parenchyma cells		(b) They possess a peripheral cytoplasm as well as a large
35.	Sieve tubes are better suited for translocation, because		vacuole
	[NCERT]		(c) Distinct proteinaceous inclusions, the P-proteins are
	(a) Possess broader lumen and perforated cross walls		seen evenly distributed throughout the lumen
	(b) Are broader than long		(d) Long, slender, tube-like structures arranged in
	(c) Possess bordered pits		longitudinal series
	(d) Possess no end walls		
36.	Collenchyma differs from parenchyma in having		(e) They are devoid of nucleus at maturity
	(a) Living protoplasm (b) Cellulose walls	47.	
	(c) Vacuoles (d) Pectin deposits at corners		(a) Bast fibre (b) Wood fibre
37.	Cystoliths sometimes deposited in plant cells are crystals of (aggregation of) [AIIMS 1999; BVP 2004;		(c) Heart wood (d) Libriform fibre
	(aggregation of) [AIIMS 1999; BVP 2004; RPMT 2006; MP PMT 2010; Odisha JEE 2010]		. The casparian strips of root endoderm contain a mixture of
	(a) Calcium oxalate (b) Calcium carbonate		[CBSE PMT 1994; BHU 1994; HP PMT 2005 Kerala PMT 2008
	(c) Magnesium carbonate (d) Glucosides		
38.	Trachea, tracheids, wood fibres and parenchyma tissues are		
	found in [CPMT 2003]	40	157 = 5
	(a) Xylem (b) Phloem	49	
20	(c) Cambium (d) Cortex In the following pairs where do you get lignin in both the		
39.	element [WB JEE 2008]		
	(a) Trachid and Collenchyma	50	
	(b) Sclerenchyma and sieve tube		(a) Thick cell wall and large intercellular spaces(b) Thick cell wall and no intercellular space
	(c) Sclerenchyma and trachea		
	(d) Parenchyma and endodermis		(d) Thin cell wall and no intercellular spaces

			BOOK DEPOT 1960
51.	The root apex is subterminal because it	66.	Which of the following are primary meristems
	[NCERT; Kashmir MEE 1995]		(a) Pleurome (b) Protoderm
	(a) Is covered by tunica cells (b) Is covered by root hairs		(c) Intercalary meristem (d) All the above
	(c) Has many corpus cells (d) Is covered by root cap	67.	Collenchymatous tissue is found in [CBSE PMT 1990]
52.	Root cap in dicots is formed from		(a) Climbing plants
	(a) Protoderm (b) Ground meristem		(b) Aquatic plants
	(c) Calyptrogen (d) Procambium		(c) Woody climbers
53.	One of the characteristic of sieve tube is [WB JEE 2008]	60	(d) Herbaceous climbers
	(a) It is a part of phloem	68.	Parenchymatous tissue is characterised by the
	(b) Function is transport of inorganic solutes		[JIPMER 2002; MP PMT 2004] (a) Presence of uniform thickening
	(c) It is dead cell		(b) Presence of thickening in the corners
	(d) Sieve plate is not present		(c) Presence of intercellular spaces
54.	Interfasicular cambium is a [WB JEE 2010]		(d) Presence of lignified walls
	(a) Primary meristematic tissue	69.	The histogens are classified on the basis [Manipal 2005]
	(b) Primordial meristem		(a) Cells they contain
	(c) Type of protoderm		(b) Cells they give rise to future tissue
			(c) Meristematic activity
	(d) Secondary meristematic tissue		(d) Cell division
55.	Which of the following is a complex tissue [CPMT 2010]	70.	Which of the following are simple tissues [CPMT 2000]
	(a) Parenchyma (b) Collenchyma		(a) Parenchyma, xylem and phloem
	(c) Xylem (d) Schlerenchyma		(b) Parenchyma, collenchyma and sclerenchyma
56.	Safranine stains which elements of the tissue		(c) Parenchyma, xylem and collenchyma
	(a) Starch elements (b) Lignified elements		(d) Parenchyma, xylem and sclerenchyma
	(c) Protein elements (d) Hard bast	71.	Bordered pits are found in
57.	Laticiferous vessels are found in [CPMT 1993]		(a) Phloem (b) Protoxylem
	(a) Xylem tissue (b) Phloein tissue	70	(c) Metaxylem (d) Pith
	(c) Cortex (d) None of the above	72.	The plant tissues commonly found in fruit walls of nuts and pulp of some fruits like guava are termed as
58.	Term 'Leptome' is a synonym of		[NCERT; AMU (Med.) 2009]
	(a) Companion cells (b) Sieve elements		Or
	(c) Phloem fibres (d) Phloem parenchyma		Pear fruits are gritty due to the presence of [J & K CET 2012]
59.	The calyptrogen of the root apex forms [MP PMT 2003]		Or
	(a) Rhizoids (b) Root nodule		Tissue composed of non-parenchymatous cells and have
	(c) Root hairs (d) Root cap		isodiametric or irregular shape is called
60.	Histogen theory is more applicable for [CPMT 1999]		(a) Fibres (b) Tracheids
	(a) Root apex (b) Shoot apex		(c) Sclereids (d) Vessels
	(c) Meristematic tissue (d) None of these	73.	Promeristem gives rise to which meristem [MP PMT 1997]
61.			(a) Secondary (b) Lateral
J1.			(c) Primary (d) Apical
	(a) Phellem (b) Procambium (c) Interfasicular cambium (d) Fasicular cambium	74.	Starch sheath is another name of [AMU (Med.) 2009]
62.			(a) Hypodermis (b) Epidermis
02.	In which of the following phloem parenchyma is absent		(c) Casparian strip (d) None of these
	(a) Maize (b) Sunflower	75.	Sieve tubes have
	(c) Guava (d) Banyan		(a) Apical and oblique septa
63.	Meristematic tissue responsible for increase in girth of tree trunk is [RPMT 2002: NEET (Karnataka) 2013]		(b) Perforated and longitudinal septa
			(c) Perforated and oblique septa
54.	(c) Primary meristem (d) Apical meristem		(d) Simple oblique wall
J-2.	Function of storage is performed by [BHU 1999]	76.	Which one of the following statements pertaining to plant
	(a) Parenchyma (b) Sclerenchyma (c) Phloem (d) All the above		structure is correct [AIIMS 2005]
55			(a) Cork have no stomata, but lenticels carry out transpiration
55.	On the basis of origin, meristematic tissues can be classified under how many groups		(b) Passage cells help in transfer of food from cortex to
			phloem
			(c) Sieve tube elements possess cytoplasm but not nuclei
	(c) 4 (d) 5		(d) The shoot apical meristem has a guiescent centre

- (c) Epiphyttes
- (d) Hydrophytes
- The length of different internodes in a culm of sugarcane is [CBSE PMT 2008] variable because
 - (a) Size of leaf lamina at the node below each internode
 - (b) Intercalary meristem
 - (c) Shoot apical meristem
 - (d) Position of axillary buds
- Vascular bundles in which phloem is found on both sides of xylem are called (In which of the following phloem occurs in two patches) [CBSE PMT 1992; BVP 2003]
 - (a) Collateral
- (b) Bicollateral
- (c) Radial
- (d) Amphicribral
- Amphivasal or leptocentric vascular bundles are found in 7.

Or

An example of monocots showing secondary growth in stems is

- (a) Cycas and Dryopteris
- (b) Dracaena and Yucca
- (c) Helianthus and Cucurbita(d) Maize and wheat
- A root hair is formed by

[EAMCET 1995]

- (a) Epidermal cell
- (b) Endodermal cell
- (c) Cortical cell
- (d) Pericycle cell
- The layer of cells outside the phloem meant for giving rise to the root branches is called [Kerala CET 2003]
 - (a) Cambium
- (b) Carpus
- (c) Endodermis
- (d) Pericycle
- The root cap is not used in absorption of water due to 10.

[Odisha JEE 2011]

- (a) Presence of root hairs
- (b) Absence of root hairs
- (c) Its presence in elongation zone
- (d) None of these
- In root, pericycle gives rise to
 - (a) Branch root and cork cambium
 - (b) Cortex and pith
 - (c) Epidermis and vascular bundles
 - (d) Xylem and phloem

- Vascular bundles in the stem of Cucurbita or Lagenaria are [AIIMS 1992; KCET 1999; BHU 2001]
 - (a) Collateral
- (b) Bicollateral
- (c) Radial

13.

- (d) Inverted
- Periblem gives rise to
- [MP PMT 2001; RPMT 2005]
- (a) Pericycle
- (b) Cortex
- (c) Medulla 14. Cuticle is secreted by
- (d) Epidermis
- (b) Endodermis
- (a) Epidermis
- (d) Hypodermis
- (c) Both (a) and (b) 15. Vascular bundles are derived from (originate from)
 - (a) Dermatogen
 - (b) Periderm
 - (c) Endogenous tissue the procambial strand or plerome
 - (d) Cortex
- The composition of stele is 16.

[Odisha JEE 2011]

- (a) Pith, vascular bundle
- (b) Pericycle, pith
- (c) Endodermis, pericycle
- (d) Endodermis, pericycle, pith
- Bulliform or motor cells are present in
 - (a) Dicot stem
 - (b) Upper epidermis of dicot leaves
 - (c) Lower epidermis of monocot leaves
 - (d) Upper epidermis of monocot leaves
- [NCERT; CBSE PMT (Pre.) 2011] 18. Ground tissue includes
 - (a) All tissues internal to endodermis
 - (b) All tissues external to endodermis
 - (c) All tissues except epidermis and vascular bundles
 - (d) Epidermis and cortex
- 19. Radial vascular bundle can be seen in

[CPMT 1996; MP PMT 2005]

- (a) Leaf
- (b) Dicot root
- (c) Stem
- (d) Flower
- Water stomata are found in 20.
 - (a) Plants inhabiting humid region
 - (b) Plants inhabiting dry regions
 - (c) All plants
 - (d) Plants lacking normal stomata
- Raphides are found in
- [MP PMT 1996]

[Pb. PMT 1999]

- (a) Citrus (c) Nerium
- (b) Colocasia (d) Mango
- Mesarch xylem is common in 22

 - (a) Ferns
- (b) Bryophytes
- (c) Dicots (d) Monocots In plants like Nymphaea which is attached emerged
- hydrophyte, the stomata are present on (a) Adaxial (upper) surface of leaf
 - (b) Abaxial (lower) surface of leaf
 - (c) On both surface of leaf
 - (d) None of the above

400 Anatomy of Flowering Plants Multiple epidermis on dorsal and ventral side of the leaf is [CBSE PMT 1990; BHU 1994] found in (b) Ficus benghalensis (a) Zea mays (d) Nerium oleander (c) Mangifera indica Amphiphloic (bicollateral) condition of stele means that 25. [RPMT 1997; BVP 2003] (a) Phloem is surrounded by xylem (b) Phloem is on both sides of xylem (c) Phloem is internal to xylem (d) Phloem is external to xylem 35. 26. When formation of metaxylem is in a centripetal manner, [BHU 1994] the xylem is (b) Exarch (a) Endarch 36. (d) Radial (c) Mesarch 27. Druse is a crystal or deposit of (b) Calcium carbonate (a) Calcium oxalate (c) Starch Silica 37. The most primitive type of stele is [CPMT 2001] 28. (a) Eustele (b) Solenostele (c) Protostele (d) Siphonostele 38. Match the items in Column - I with Column - II and choose 29. the correct option Column - I Column - II 39. Radial Vascular Bundle Cucurbita pepo 1. A. 2 Dracaena B Collateral Vascular Bundle Bicollateral Vascular Bundle Roots of C. angiosperms Amphicribal Vascular Bundle Sunflower stem D. Amphivasal Vascular Bundle Fern [Kerala PMT 2007] (a) A-3, B-4, C-1, D-5, E-2(b) A-2,B-3,C-1,D-5,E-4(c) A-3, B-4, C-5, D-1, E-2(d) A-4, B-5, C-1, D-2, E-3(e) A-3, B-1, C-2, D-4, E-5[AIIMS 2002] Passage cells are found in 30. (a) Dicot stem (b) Aereal root (c) Monocot root (d) Monocot stem 31. Trabaculae is the transformation of [MP PMT 2003] (b) Endodermis (a) Pericucle (d) Phloem (c) Xylem A bicollateral vascular bundle has the following arrangement 32. 43. [KCET 2004] of tissues (a) Outer phloem - outer xylem - middle cambium - inner xylem - inner phloem Outer cambium - Outer phloem - middle xylem - inner 44. phloem - inner cambium (c) Outer phloem - outer cambium - middle xylem - inner cambium - inner phloem

(d) Outer xylem - outer cambium - middle phloem - inner

cambium - inner xylem

Amphivasal vascular bundle possess **IRPMT 20061** (a) Xylem around phloem (b) Phloem around xylem (c) Phloem on both sides of xylem (d) Phloem towards centre and xylem towards periphery A dicot plant in which scattered vascular bundles are present [AFMC 2012] in stem is (a) Yucca (b) Peperomia (c) Dolichos (d) Helianthus Vascular tissue is well developed in [MHCET 2001] (b) Mesophytes (a) Hydrophytes (d) None of these (c) Xerophytes Vascular bundle in monocotyledons are considered closed, [Odisha JEE 2004; AFMC 2010; CBSE PMT (Pre.) 2012; AIPMT (Cancelled) 2015] (b) Cambium absent (a) Cambium present (c) Pericycle absent (d) None of these In the leaf vascular bundles are found in the [Kerala CET 2003] (b) Palisade tissue (a) Veins (c) Lower epidermis (d) Upper epidermis [MP PMT 2002] Protosteles are found in (a) Bryophyta (b) Gymnosperms (c) Pteridophyta (d) Angiosperms Which of the following have sunken stomata [RPMT 2002] (b) Mangifera (a) Nerium (c) Hydrilla (d) Zea mays Some vascular bundles are described as open because these [NCERT; CBSE PMT (Mains) 2011] (a) Possess conjunctive tissue between xylem and phloem (b) Are not surrounded by pericycle (c) Are surrounded by pericycle but no endodermis (d) Are capable of producing secondary xylem and phloem 41. Vascular cambium in dicot root develops from [DPMT 2004] In dicot root, initiation of lateral root and vascular cambium during secondary growth takes place from INCERTI (a) Endodermis (b) Pericycle (c) Conjunctive parenchyma (d) Both (b) and (c) The large, empty and colourless cells present at intervals on the upper surface of grass leaf are called [Kerala PMT 2006, 11] (a) Bulliform cells (b) Palisade parenchyma (d) Accessory cells (c) Spongy parenchyma (e) Passage cells Amphicribal or hadrocentric vascular bundles are present in the stem of (b) Dracaena (a) Selaginella (c) Cucurbita (d) Zea mays [AFMC 2000] In free floating plant, the stomata are (a) Absent (b) Present on upper surface

(c) Present on both the surface

(d) Present on lower surface

Pith cells are found in **IRPMT 19951** 5. In monocot leaf [CBSE PMT 1990] (a) Epidermis (b) Endodermis (a) Bulliform cells are absent from the epidermis (c) Pericycle (d) Lenticels (b) Veins form a network 46. Dorsiventral leaf has [Kerala CET 2002] (c) Mesophyll is well differentiated into these parts (a) Stomata on both side (b) Stomata on lower surface (d) Mesophyll is not differentiated into palisade and spongy (c) Stomata on upper surface (d) No stomata parenchyma 47. Root hairs are found [NCERT; Kerala CET 2003; NEET 2017] Find out the wrong statement about angiosperm roots (a) In the zone of maturation (b) Adventitious roots [KCET 2012] (c) On the root cap (d) Apical meristem (a) Cuticle is absent in young stages Raphides are needle-like crystals of calcium oxalate which (b) The apex is protected by root cap are specially found in [Bihar MDAT 1995; MP PMT 1996; CPMT 2000; Odisha JEE 2004] (c) Vascular bundles are collateral (a) Pistia (b) Rose (d) Xylem is centripetal in growth in the young roots (d) Dahlia (c) Asparagus A major characteristic of the monocot root is the presence of 7. 49. Which of the following do not have stomata [AIPMT (Cancelled) 2015] (a) Xerophytes (b) Mesophytes (a) Scattered vascular bundles (c) Hydrophytes (d) Submerged hydrophytes (b) Vasculature without cambium Passage cells are present in 50. [KCET 2000] (c) Cambium sandwiched between phloem and xylem (a) Epidermis (b) Endodermis along the radius (c) Xylem (d) Lenticels and hydathodes (d) Open vascular bundles When xylem and phloem are separated by a strip of 51. 8. The correct situation of mesophyll in isobilateral grass leaf is cambium it is called [KCET 1998] (a) Collateral and open (b) Collateral and closed (a) Palisade towards adaxial surface (c) Bicollatoral and open (d) Concentric and closed (b) Palisade towards abaxial surface 52. Cortex is the region found between [NEET (Phase-II) 2016] (c) Undifferentiated mesophyll (a) Endodemis and vascular bundle (d) Palisade along both the surface (b) Epidermis and stele 9. Leaf mesophylls are composed of [Odisha JEE 2008] (c) Pericycle and endodermis (a) Pallisade parenchyma (b) Spongy parenchyma (d) Endodermis and pith (c) Both of them (d) None of these Internal structure of root, stem and leaf 10. Vascular bundles are scattered in 1. Exarch and polyarch vascular bundles occur in [Kerala CET 2002; CPMT 1990] [MP PMT 2000, 06] (a) Bryophytes (b) Dicot root (a) Monocot stem (b) Monocot root (c) Dicot stem (d) Monocot stem (c) Dicot stem (d) Dicot root Generally hypodermis in monocots is composed of 2. Bicollateral conjoint vascular bundles have (a) Parenchyma (b) Sclerenchyma [Kerala PMT 2006] (c) Collenchyma (d) Chlorenchyma (a) Xylem and phloem, which are arranged in an alternate Kranz anatomy is found in [CPMT 1998] manner on different radii (a) Monocots (b) Dicots (b) Xylem and phloem, which are situated at the same (c) Both (a) and (b) (d) None of these radius and it has two groups of phloem along the two Which of the following is not a characteristic feature of the sides of xylem (inside and outside) anatomy of dicotyledonous root (c) Xylem and phloem in same radius but it has only one (a) Radial vascular bundles group phloem outside the xylem (b) Secondary growth (d) Phloem surrounds the xylem tissues (c) Pith little or absent (e) Xylem surrounds the phloem tissues (d) Vascular bundles 15 - 20 Velamen tissue in orchids is found in 3. 14. Origin of lateral root of secondary root is (a) Shoot (b) Root (a) Exogenous (b) Endogenous (c) Leaves (d) Flowers (c) Lysigenous (d) Schizogenous Casparian thickenings are found in the cells of [CPMT 1999; KCET 2006; Odisha JEE 2011] In a vertical section of a dorsiventral leaf, the protoxylem in its midrid bundle Or [BHU 1994] In dicot roots, cells of which region show casparian strips (a) Faces the dorsal epidermis of the leaf [RPMT 1997; CBSE PMT 1999; Odisha JEE 2005] (b) Faces the ventral epidermis of the leaf (a) Pericycle of the root (b) Endodermis of the root Is not distinct (c) Pericycle of the stem

(d) Is surrounded by metaxylem

(d) Endodermis of the stem

- The annular and spirally thickened conducting elements generally develop in the protoxylem when the root or stem is [CBSE PMT 2009]
 - (a) Maturing
- (b) Elongating
- (c) Widening
- (d) Differentiating
- 17. In barley stem vascular bundles are [CBSE PMT 2009]
 - (a) Open and scattered
 - (b) Closed and scattered
 - (c) Open and in a ring
 - (d) Closed and radial
- Anatomically fairly old dicotyledonous root is distinguished from the dicotyledonous stem by

[CBSE PMT 2009, 14; Odisha JEE 2011]

- (a) Absence of secondary xylem
- (b) Absence of secondary phloem
- (c) Presence of cortex
- (d) Position of protoxylem
- 19. Palisade parenchyma is absent in leaves of

[CBSE PMT 2009]

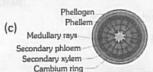

- (a) Sorghum
- (b) Mustard
- (c) Soybean
- (d) Gram
- 20. Exarch xylem is found in
- [CBSE PMT 1990; KCET 1999]
- (a) Root
- (b) Stem
- (c) Leaf
- (d) Rachis
- 21. The vascular cambial ring of a dicot stem is
 - (a) Primary in origin
- (b) Secondary in origin
- (c) Embryonic in origin
- (d) Tertiary in origin
- (e) Partly primary and partly secondary in origin
- 22. Consider the following statements
 - (A) In a dicot root, the vascular bundles are collateral and
 - (B) The inner most layer of cortex in a dicot root is endodermis
 - (C) In a dicot root, the phloem masses are separated from the xylem by parenchymatous cells that are knwon as the conjunctive tissue

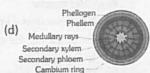

Of these statements given above [Kerala PMT 2008]

- (a) A is true, but B and C are false
- (b) B is true, but A and C are false
- (c) A is false, but B and C are true
- (d) C is false, but A and C are true
- (e) C is true, but A and B are false
- Which of the following figure of dicot stem is correctly labelled [NCERT]

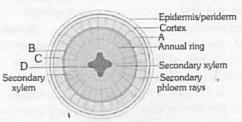

Phellem Phellogen
(b) Medullary rays
Secondary xylem
Secondary phloem
Cambium ring

 The following figure is old typical dicot root. Identify A, B, C and D [NCERT]

- (a) A Secondary phloem, B Primary xylem, C Primary phloem, D – Vascular cambium
- (b) A Primary phloem, B Primary xylem, C Secondary phloem, D – Vascular cambium
- (c) A Secondary phloem, B Vascular cambium, C Primary phloem, D Primary xylem
- (d) A Primary phloem, B Vascular cambium, C Secondary phloem, D – Primary xylem
- 25. Vascular bundles in dicot stem are

[MHCET 2001; Odisha JEE 2012; PET (Pharmacy) 2013]

- (a) Conjoint and collateral
- (b) Conjoint and closed
- (c) Conjoint, collateral and open
- (d) Collateral and open
- Which of the following is correct sequence of layers in typical monocot root (from outer surface to inside)

[CPMT 2005]

- (a) Pericycle, cortex, endodermis, epiblema
- (b) Epiblema, endodermis, cortex, pericycle
- (c) Epiblema, cortex, endodermis, pericycle
- (d) Epiblema, pericycle, cortex, endodermis
- 27. Monocot root differs from dicot root in

[NCERT; AMU (Med.) 2005; CBSE PMT (Mains) 2012]

- (a) Presence of more than six xylem bundle
- (b) Well developed pith
- (c) Absence of secondary growth
- (d) All of these
- 28. Pith is a central part of the ground tissue generally made up of [J & K CET 2005]
 - (a) Parenchyma
- (b) Collenchyma
- (c) Chlorenchyma
- (d) Sclerenchyma
- 29. In a dorsiventral leaf, location of palisade tissue and phloem respectively are [NCERT; RPMT 1999]
 - (a) Abaxial and abaxial
- (b) Adaxial and abaxial
- (c) Adaxial and adaxial
- (d) Abaxial and adaxial
- T.S. of stem of Cucurbita can be identified from the T.S. of sunflower stem by the presence of
 - (a) Bicollateral vascular bundles
 - (b) Conjoint vascular bundles
 - (c) Scattered vascular bundles
 - (d) Cambium in the vascular bundles

Which of the following is seen in a monocot root

(a) Large pith

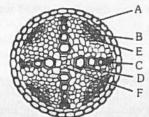

31.

(b) Vascular cambium

[DPMT 2004]

- (c) Endarch xylem
- (d) Medullary ray
- 32. In monocot stem, following is absent(a) Endodermis(b) Hy
 - (b) Hypodermis
 - (c) Cortex
- (d) Both (a) and (b)

In the diagram of T.S. of Stele of Dicot Root, the different parts have been indicated by alphabets; choose the answer in which these alphabets correctly match with the parts they **IKCET 20041**

(a) A = Endodermis

B = Conjunctive tissue

C = Metaxylem

D = Protoxylem

E = Phloem

F = Pith

(b) A = Endodermis

B = Pith

C = Protoxylem

= Metaxylem

E = Protoxylem

F = Conjunctive tissue

(c) A = Pericycle

B = Conjunctive tissue

C = Metaxylem

D = Protoxylem

E = Phloem

(d) A = Endodermis

B = Conjunctive tissue

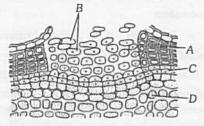

C = Protoxylem

D = Metaxylem

E = Phloem

F = Pith

In the diagram of lenticel identify the parts as A, B, C, D

[KCET 2007]

- (a) A phellem, B periderm, C phellogen, D phelloderm
- (b) A phellem, B complementary cells, C phelloderm, D - periderm
- (c) A complementary cells, B phellogen, C phelloderm, D - periderm
- (d) A complementary cells, B phellem, C periderm, D – phelloderm
- 35. Centripetal xylem is the characteristic of
 - (a) Roots

(b) Stems

(c) Leaf

(d) Petiole

- 36. In monocot roots which types of vascular bundles are found [BHU 2003]
 - (a) Collateral, conjoint and closed
 - (b) Radial V.B. with exarch xylem
 - (c) Bicollateral, conjoint and closed
 - (d) Radial V.B. with endarch xylem
- Conjoint, collateral and closed vascular bundle is found in

[RPMT 1995, 2002; CPMT 1998; BHU 2002; BCECE 2005; AMU (Med.) 2009]

- (a) Monocot stem
- (b) Monocot root
- (c) Dicot stem
- (d) Dicot root

38. Collenchyma tissue is present in

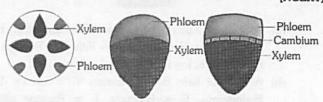

[RPMT 1995]

ICPMT 20041

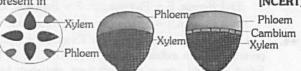

Collenchymatous hypodermis is characteristics of

- (a) Dicot stem
- (b) Monocot stem
- (c) Dicot root
- (d) Flowers
- Largest number of chloroplast is found in
- (a) Palisade tissue
- (b) Spongy tissue
- (c) Transfusion tissue
- (d) Bundle sheath cells
- Which type of vascular bundles are found in A, B and C

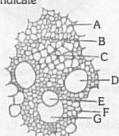

[NCERT]

- (a) Bicollateral; Concentric; Radial
- (b) Open collateral conjoint; Close collateral conjoint; Radial
- (c) Close collateral conjoint; Open collateral conjoint; Radial
- (d) Radial; Close collateral conjoint; Open collateral conjoint
- The following types of vascular bundles (A, B and C) are present in [NCERT]

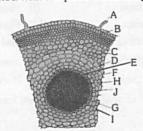

- (a) Monocot stem and leaf, dicot root, monocot leaf respectively
- (b) Root, monocot stem and leaf, dicot stem respectively
- (c) Root, stem, leaf respectively
- (d) Stem, root, leaf respectively
- The following diagrams shows the cross-section of the vascular bundle of monocot stem given aside, different parts have been indicated by alphabets; choose the option in which these alphabets have been correctly matched with the parts which they indicate INCERT

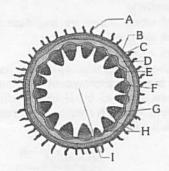

- (a) A = Bundle cap, B = Metaxylem, C = Metaphloem, D = Protoxylem, E = Protophloem, F = Lysigenous cavity, G = Xylem parenchyma
- (b) A = Bundle sheath, B = Primary phloem, C = Secondary phloem, D = Primary xylem, E = Secondary xylem, F = Xylem fibres, G = Hydathode
- (c) A = Bundle cap, B = Metaphloem, C = Protophloem, D = Protoxylem, E = Metaxylem, F = Lysigenous cavity, G = Xylem parenchyma
- (d) A = Bundle sheath, B = Broken phloem, C = Metaphloem, D = Metaxylem, E = Protoxylem, F = Xylem parenchyma, G = Lysigenous cavity

43. The following diagram illustrates the TS of monocot root in which certain parts have been indicated by alphabets, choose the right answer in which these alphabets have been correctly matched with the parts which they indicate[NCERT]

UNIVERSAL BOOK DEPOT 1960

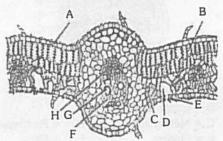

- (a) A = Root hair, B = Cortex, C = Epiblema, D = Pericycle, E = Endodermis, F = Pith, G = Passage cell, H = Phloem, I = Protoxylem, J = Metaxylem
- (b) A = Root hair, B = Epiblema, C = Cortex, D = Endodermis, E = Pericycle, F = Passage cell, G Phloem, H = Pith, I = Protoxylem, J = Metaxylem
- (c) A = Root hair, B = Epiblema, C = Cortex, D = Endodermis, E = Passage cell, F = Pith, G = Pericycle, H = Metaxylem, I = Phloem, J = Protoxylem
- (d) A = Root hair, B = Epiblema, C = Cortex, D = Endodermis, E = Passage cell, F = Pericycle, G = Pith, H = Phloem, I = Metaxylem, J = Protoxylem
- 44. The following diagram shows the TS of dicot stem, certain parts have been indicated by A, B, C, D, E, F, G, H and I. Select the right answer in which these alphabets have been correctly matched with the parts which they indicate [NCERT]

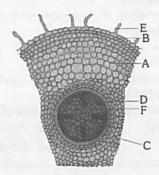

- (a) A = Epidermal hairs, B = Epidermis, C = Parenchyma, D = Hypodermis (Collenchyma), E = Starch sheath, F = Vascular bundle, G = Bundle cap, H = Medulla or pith, I = Medullary rays
- (b) A = Epidermal hairs, B = Epidermis, C = Hypodermis (Collenchyma), D = Starch sheath, E = Parenchyma, F = Vascular bundle, G = Bundle cap, H = Medulla or pith, I = Medullary rays
- (c) A = Epidermal hairs, B = Epidermis, C = Hypodermis (Collenchyma), D = Parenchyma, E = Starch sheath, F = Bundle cap, G = Vascular bundle, H = Medullary rays, I = Medulla or pith
- (d) A = Epidermis, B = Epidermal hairs, C = Parenchyma, D = Starch sheath, E = Hypodermis (Collenchyma), F = Vascular bundle, G = Bundle cap, H = Medulla or pith, I = Medullary rays

45. The following diagram shows the TS of dicot leaf passing through the midrib, some parts have been indicated by alphabets. Choose the answer in which A, B, C, D, E, F, G and H have been correctly matched with the parts which they indicate [NCERT]

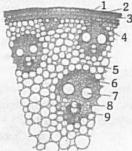

- (a) A = Epidermis, B = Palisade parenchyma, C = Spongy parenchyma, D = Stomata, E = Guard Cells, F = Phloem, G = Metaxylem, H = Protoxylem
- (b) A = Epidermis, B = Palisade parenchyma, C = Spongy parenchyma, D = Stomata, E = Guard cells, F = Endodermis, G = Xylem, H = Phloem
- (c) A = Epidermis, B = Palisade parenchyma, C = Spongy Parenchyma, D = Sub stomatal cavity, E = Guard cells, F = Phloem, G = Metaxylem, H = Protoxylem
- (d) A = Epidermis, B = Spongy parenchyma, C = Palisade parenchyma, D = Stomata, E = Guard cells, F = Phloem, G = Metaxylem, H = Protoxylem
- 46. The following diagram shows the TS of dicot root, certain parts have been indicated by letters, select the option in which these letters have been correctly matched with the parts which they indicate [NCERT]

- (a) A = Cortex, B = Epiblema, C = Pith, D = Endodermis, E = Root hair, F = Pericycle
- (b) A = Epiblema, B = Endodermis, C = Cortex, D = Root hair, E = Pith, F = Pericycle
- (c) A = Cortex, B = Pith, C = Epiblema, D = Endodermis, E = Root hair, F = Pericycle
- (d) A = Epiblema, B = Root hair, C = Cortex, D = Endodermis, E = Pith, F = pericycle

47. The given below diagram shows the T.S. of monocot stem, some parts have been indicated by numbers. Select the answer in which these numbers have been correctly matched with the parts which they indicate INCERTI

- (a) 1 Cuticle, 2 Epidermis, 3 Sclerenchymatous hypodermis, 4 - Sclerenchymatous sheath, 5 -Parenchymatous sheath, 6 - Protoxylem, 7 - Metaxylem, 8 - Phloem, 9 - Water cavity
- (b) 1 Cuticle, 2 Epidermis, 3 Sclerenchymatous hypodermis, 4 - Sclerenchymatous sheath, 5 -Parenchymatous sheath, 6 - Phloem, 7 - Protoxylem, 8 -Metaxylem, 9 - Water cavity
- (c) 1 Cuticle, 2 Epidermis, 3 Sclerenchymatous sheath, 4 - Sclerenchymatous hypodermis, 5 - Parenchymatous sheath, 6 - Phloem, 7 - Metaxylem, 8 - Protoxylem, 9 -Water cavity
- (d) 1 Cuticle, 2 Epidermis, 3 Sclerenchymatous hypodermis, 4 - Sclerenchymatous sheath, 5 -Parenchymatous sheath, 6 - Phloem, 7 - Metaxylem, 8 -Protoxylem, 9-Water cavity

Secondary growth

- 1. In dicot stem, the secondary growth takes place by
 - (a) Primary cambium
 - (b) Secondary cambium
 - (c) Development of cambium in stele region
 - (d) Development of cambium in stele and in the cortical
- 2. Which one of the following is not correct [AMU (Med.) 2010]
 - (a) Early wood is characterized by large number of xylary elements
 - (b) Early wood is characterized by vessels with wider cavities
 - (c) Late wood is characterized by large number of xylary
 - (d) Late wood is characterized by vessels with narrower
- Conduction of sap in plants occurs through
 - (a) Heartwood
- (b) Sapwood
- (c) Xylem
- (d) All the above
- 4. "Sap wood" is otherwise called

[J & K CET 2008; Kerala PMT 2009]

- (a) Duramen
- (b) Alburnum
- (c) Pith
- (d) Medullary rays
- The function of cork cambium (phellogen) is to produce 5. [Odisha JEE 2010]
 - (a) Cork and secondary cortex
 - (b) Secondary xylem and secondary phloem
 - (c) Cork
 - (d) Secondary cortex and phloem

Vascular tissues in flowering plants develop from

[KCET 1998; CBSE PMT 2008]

- (a) Periblem
- (b) Dermatogen
- (c) Phellogen
- (d) Plerome
- In dicot roots, cork cambium is derived from
- (b) Hypodermis
- (a) Epidermis (c) Cortex
- (d) Pericycle
- Periderm is made up of 8.
- [MP PMT 1995, 2010]
- (a) Phellem
- (b) Phellogen
- (c) Phelloderm
- (d) All the above
- If four radial vascular bundles are present, then the structure will be [CBSE PMT 2002]
 - (a) Monocot stem
- (b) Monocot root
- (c) Dicot stem
- (d) Dicot root
- Secondary growth is absent in
 - (a) Dicot stem
- (b) Gymnosperms
- (c) Monocot stem
- (d) Dicot root
- Complementary cells are found in
 - [Odisha JEE 2012] (b) Endodermis
 - (a) Pericycle (c) Lenticels
- (d) Pith
- 12. Fascicular cambium found in dicot stem is a
 - (a) Secondary meristem
- (b) Primary meristem
- (c) Intercalary meristem
- (d) Apical meristem
- Which of the following meristems is responsible for extrastelar secondary growth in dicotyledonous stem

ICBSE PMT 19981

- (a) Phellogen
- (b) Intrafascicular cambium
- (c) Interfascicular cambium (d) Intercalary meristem
- Heartwood differs from sapwood in [CBSE PMT (Pre.) 2010] 14.
- (a) Being susceptible to pests and pathogens

 - (b) Presence of rays and fibres
 - (c) Absence of vessels and parenchyma
 - (d) Having dead and non-conducting elements
- Youngest layer of secondary xylem in wood of dicot stem is [CPMT 1993] located just
 - (a) Outside the cambium
- (b) Inside the cambium
- (c) Outside pith
- (d) Inside the cortex
- Annual rings are distinct in plants growing in 16.
 - (a) Tropical regions
- (b) Arctic region
- (c) Grasslands
- (d) Temperate region
- Read the different components from (A) to (D) in the list given below and tell the correct order of the components with reference to their arrangement from outer side to inner side in a woody dicot stem [AIPMT 2015]
 - (A) Secondary cortex
- (B) Wood
- (C) Secondary phloem
- (D) Phellem
- (a) (A), (B), (D), (C)
- (b) (D), (A), (C), (B)
- (c) (D), (C), (A), (B)
- (d) (C), (D), (B), (A)
- Growth rings are well marked in trees growing in

 - (a) Shimla (c) Madras
- (b) Bombay (d) Calcutta
- As secondary growth proceeds, in a dicot stem, the 19. **[KCET 2006]** thickness of
 - (a) Sapwood increases
 - (b) Heartwood increases
 - (c) Both sapwood and heartwood increases
 - (d) Both sapwood and heartwood remains the same

- External protective tissues of plants are (of dicot stem are)
 - (a) Cork and pericycle
- (b) Cortex and epidermis
- (c) Pericycle and cortex
- (d) Epidermis and cork
- Cork cambium is a 21. (a) Secondary meristem
- [MHCET 2000] (b) Apical meristem
- (c) Intercalary meristem
- (d) Primary meristem
- The cambium which produces cork is known as

IEAMCET 1993: RPMT 1997; CPMT 1999; HPMT 2005]

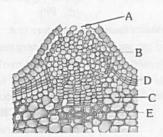

The common bottle cork is a product of

[NCERT; CBSE PMT (Pre.) 2012] Or

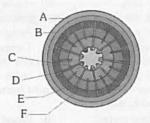

The meristem that is parallel to the longitudinal axis of the plant is

- (a) Phelloderm
- (b) Phellogen
- (c) Periblem
- (d) Periderm
- The cork cambium, cork and secondary cortex are collectively 23. called[NCERT; Kashmir MEE 1995; CBSE PMT (Pre.) 2011]
 - (a) Phellem
- (b) Phelloderm
- (c) Phellogen
- (d) Periderm
- Identify the correct combination of labelling a lenticel

[NCERT]

- (a) A pore, B complimentary cells, C cork, D cork cambium, E - secondary cortex
- (b) A pore, B cork, C complimentary cells, D cork cambium, E - secondary cortex
- (c) A pore, B cork cambium, C secondary cortex, D cork, E - complimentary cells
- (d) A pore, B secondary cortex, C cork cambium, D cork, E - complimentary cells
- The following figure showing secondary growth in dicot stem. Identify A, B, C, D, E and F [NCERT]

- (a) A Phellem, B Phellogen, C Cambium ring, D -Secondary xylem, E - Secondary phloem, F -Medullary rays
- (b) A Phellogen, B Phellem, C Medullary rays, D -Secondary xylem, E - Secondary phloem, F -Cambium ring
- (c) A Phellem, B Phellogen, C Medullary rays, D -Secondary phloem, E - Secondary xylem, F -
- (d) A Phellem, B Phellogen, C Medullary rays, D -Secondary xylem, E - Secondary phloem, F -Cambium ring

- In dicot stem secondary growth is due to the activity of 26. [Pb. PMT 2004, 05]
 - (a) Apical meristem
- (b) Lateral meristem
- (c) Cork
- (d) Back
- The cell wall is impermeable to water and deposition of 27. [CPMT 1998] suberin is also found in
 - (a) Bast
- (b) Cork
- (c) Bark

28.

- (d) Xylem
- Secondary growth is absent in (a) Hydrophytes
 - (b) Mesophytes

[CPMT 1998]

- (c) Halophytes
- (d) Xerophytes
- Girth of a dicot stem is increased by 29
 - [Pune CET 1998] (b) Cambium
 - (a) Xylem
- (c) Phloem
- (d) Ground tissue
- 30. Tyloses are found in
 - [MP PMT 1996; KCET 2010; Odisha JEE 2012]
 - (a) Secondary xylem
- (b) Secondary phloem
- (c) Callus tissue
- (d) Cork cells [MP PMT 2007]
- Fusiform initials form (a) Vascular rays
- (b) Treacheary elements
- (c) Ray parenchyma
- (d) Phloem parenchyma
- In the primary tissues of the stem, the cambium separating 32. xylem and phloem is called
 - (a) Procambium
- (b) Fascicular cambium
- (c) Cork cambium
- (d) Interfascicular cambium
- The trees growing in desert will 33.
 - (a) Show alternate rings of xylem and sclerenchyma
 - (b) Have only conjunctive tissue and phloem formed by the activity of cambium
 - (c) Show distinct annual rings
 - (d) Not show distinct annual rings
- 34. The bark of tree comprises

[NCERT; CPMT 1996; Pune CET 1998]

- (a) All the tissues outside the vascular cambium
- (b) All the tissues outside the cork cambium
- (c) Only the cork
- (d) The cork and secondary cortex
- Knots in stems are formed due to 35.
 - (a) Tumors formed due to bacterial infection of wounds
 - (b) Outgrowth of seconday tissue over wounds
 - Injury caused by insects
 - (d) None of the above
- 36. The vascular cambium in dicots is
- [EAMCET 1995]

[KCET 2012]

- (a) Lateral
- (b) Apical
- (c) Intercalary
- (d) Secondary
- Secondary cortex is also known as (a) Phellem
 - (b) Phelloderm
 - (c) Phellogen
- (d) Bark
- Annual growth rings are formed due to activity 38.
 - [CPMT 2004; MP PMT 2006]
 - (a) Extrastelar cambium
- (b) Intrastelar cambium
- (c) Interstelar cambium
- (d) Both (b) and (c)
- As a tree grows older, which increases rapidly in thickness 39.
 - (a) Its heart wood
- (b) Its cortex
- (c) Its sap wood
- (d) Its phloem

40. 50. For a critical study of secondary growth in plants, which one The axillary buds arise [MP PMT 2013] of the following pairs is suitable [CBSE PMT 2007] (a) Endogenously from the pericycle (a) Sugarcane and sunflower (b) Exogenously from the tissues of the main growing point (b) Teak and pine (c) Endogenously from the cambial tissues (c) Deodar and fern (d) Exogenously from the innermost cortex (d) Wheat and maiden hair fern Lenticel develops through the activity of 41. Vascular cambium is a meristematic layer that cuts off (a) Vascular cambium (b) Dermatogen [CBSE PMT 1990] (c) Phellogen (d) Intercalary meristem (a) Primary xylem and primary phloem In a stratified cambium, the fusiform initials are 42. (b) Xylem vessels and xylem tracheids [CBSE PMT 1994] (c) Primary xylem and secondary xylem (a) Long and overlap each other at the ends (d) Secondary xylem and secondary phloem (b) Short and overlap each other at the ends The waxy substance associated with cell walls of cork cells is (c) Short and arranged in horizontal tiers or cork cells are impervious to water because of the (d) Short or long and overlap each other at the ends presence or what is deposited on cork cells Intrafascicular cambium is situated in AIIMS 1992, 2004; CBSE PMT 1994; MP PMT 2000] (a) Outside the vascular bundles (a) Cutin (b) Suberin (b) In medullary rays (c) Lignin (d) Hemicellulose (c) Inside the vascular bundles Which of the following statements is / are not true (d) In between the vascular bundles A. Cork cambium is otherwise called phellogen Lenticels are 44. [NCERT; Odisha JEE 2009] B. Cork is otherwise called phellem (a) Loose cells on leaves C. Secondary cortex is otherwise called periderm (b) Subsidiary cells of stomata D. Cork cambium, cork and secondary cortex are (c) Cells for respiration in epiphytes collectively called phelloderm [Kerala PMT 2006, 07] (d) Some loose cells on bark meant for aeration (a) C and D only (b) A and B only In an annual ring, the light coloured part is known as 45. (c) B and C only (d) B and D only **IDUMET 20091** (e) A and D only (a) Early wood (b) Late wood 54. The functional xylem of dicot tree is [AFMC 2001] (c) Heartwood (d) Sapwood (a) Sap wood (b) Hard wood In old dicot stems, a major part of the wood is filled up with (c) Heart wood (d) Autumn wood tannins, resins, gums etc. This part of wood is called Which will decay faster if exposed freely [CBSE PMT 1993] (a) Hard wood (b) Heart wood (c) Sap wood (d) Soft wood (a) Soft wood (b) Heart wood 47. In summer, cambium (c) Sap wood (d) Wood with lots of fibres (a) Dies (b) Is more active In dicot stem, vascular bundles are 56. (c) Is less active (d) Is not active [NCERT; Odisha JEE 2004] What is/are true about heart wood 48. (a) Numerous scattered A. It does not help in water conduction (b) Arranged in a ring B. It is also called alurnum (c) Without cambium C. It is dark in colour but very soft (d) Surrounded by bundle sheath D. It has tracheary element which are filled with tannin, The best method to determine the age of tree is resin, etc. [NCERT; KCET 2009] [MP PMT 2004; NEET 2013] (a) B, C and D (b) A and D (a) To find out the number of branches (c) B and D (d) A, B and C (b) To count the number of annual rings (c) To measure its diameter Identify the correct statement **IKCET 20091** (d) To count the number of leaves (a) Because of marked climatic variations, plants growing Removal of ring wood of tissue outside the vascular 58. near the sea shore do not produce annual rings cambium from the tree trunk kills it because [RPMT 2005] (b) The age of the plant can be determined by its height (a) Water cannot move up (c) Healing of damaged tissue is because of the activity of (b) Food does not travel down and root become starved sclerenchyma cells (c) Shoot become starved (d) Grafting is difficult in monocot plants as they have scattered vascular bundles (d) Annual ring and not produced

408 Anatomy of Flowering Plants UNIVERSAL BOOK DEPOT 1960 After the secondary growth the youngest layer of secondary phloem in a dicot stem is located (a) Just outside the vascular cambium (b) Just inside the vascular cambium Just inside the primary phloem (d) Just outside the secondary xylem Cork is a derivative of 60. (a) Cork cambium (phellogen) or extra fascicular cambium (b) Vascular cambium (c) Fascicular cambium (d) Interfascicular cambium [AFMC 2003] Which of the following is known as wood (a) Primary xylem (b) Secondary xylem (d) Cambium (c) Secondary phloem [KCET 2001; BHU 2006] 62. Heart wood or duramen is (a) Outer region of secondary xylem (b) Inner region of secondary xylem (c) Outer region of secondary phloem (d) Inner region of secondary phloem One cannot age a tree by its rings if that tree is located in 63. which of the following forests (a) Tropical deciduous (b) Tropical evergreen (d) Temperate evergreen (c) Temperate deciduous Commercial cork is obtained from 64. [BHU 2003; MP PMT 2012] (b) Oak (Quercus suber) (a) Mango (d) Pinus (c) Ficus religiosa The pores present in the wall of plant's stem i.e., called [NCERT; CPMT 1994] Or In a plant organ which is covered by periderm and in which the stomata are absent, some gaseous exchange still takes [AIIMS 2004] place through (b) Bark (a) Lenticels (d) All the above (c) Dalipore [RPMT 1995] Lenticels are found in 66. (b) Old dicot stem (a) Young dicot stem (c) Monocot root (d) Young root Secondary growth or increase in diameter is due to [NCERT] (b) Procambium (a) Ground meristem (d) Vascular cambium (c) Cork and phelloderm In the following how the sap wood is converted into heart [RPMT 2006] (a) By degeneration of protoplast of living cells (b) Tylosis formation

(c) By deposition of resins, oil, gums

(a) Organic compounds are deposited in it

(c) It conducts water and minerals efficiently

Identify the wrong statement in context of heartwood

(d) It comprises dead elements with highly lignified walls

(b) Collenchyma

(d) Phloem

70. Which of the following is made up of dead cells [NEET 2017]

(d) All of the above

(b) It is highly durable

(a) Xylem parenchyma

(c) Phellem

69.

NCERT Exemplar Questions

A transverse section of stem is stained first with safranin and then with fast green following the usual schedule of double staining for the preparation of a permanent slide. What

CERTI

[NCERT]

would	be	the	colour	of	the	stained	xylem	and	phloem
									[N

(b) Green and red (a) Red and green (d) Purple and orange Orange and yellow

Match the following and choose the correct option from below

i. Photosynthesis, storage A. Meristem ii. Mechanical support B. Parenchuma iii. Actively dividing cells C. Collenchyma iv. Stomata D. Sclerenchyma v. Sclereids Epidermal tissue

Options: B-iii, C-v. D-ii. E-iv (a) A-i, B-i, C-ii. D-v. E-iv

(b) A-iii, C-v, B-iv, D-i. F-iii A-ii, (c) C-iii, D-ii, (d) A-v, B-iv, E-i

Match the following and choose the correct option from 3. below

Guard cells A. Cuticle Bulli form cells Single layer B. Stomata Waxy layer C.

Epidermis iv. Empty colourless cell D. [NCERT] Options

B-iv, C-i, D-ii (a) A-iii, B-ii, C-iii, D-iv (b) A-i, A-iii, C-iv, D-i B-ii, (c) C-i, D-iv (d) A-iii, B-ii,

(a) Xylem

6.

[NEET 2017]

Identify the tissue system from among the following 4.

[NCERT]

(b) Cell differentiation

(b) Xylem (a) Parenchyma (d) Phloem (c) Epidermis

Cells of this tissue are living and show angular wall 5. thickning. They also provide mechanical support. The tissue [NCERT] (b) Sclerenchyma

(d) Epidermis (c) Collenchyma

[NCERT] Epiblema of roots is equivalent to

(b) Endodermis (a) Pericycle (d) Stele (c) Epidermis

A conjoint and open vascular bundle will be observed in the **INCERT** transverse section of (a) Monocot root (b) Monocot stem

(c) Dicot root (d) Dicot stem Interfascicular cambium and cork cambium are formed due R INCERTI

Cell division (a) Cell dedifferentiation (d) Redifferentiation (c)

[NCERT] Phellogen and Phellem respectively denote (a) Cork and cork cambium

(b) Cork cambium and cork (c) Secondary cortex and cork (d) Cork and secondary cortex

UNIVERSAL BOOK DEPOT 1950

- 10. In which of the following pairs of parts of a flowering plant epidermis is absent
 - (a) Root tip and shoot tip
 - (b) Shoot bud and floral bud
 - (c) Ovule and seed
 - (d) Petiole and pedicel
- How many shoot apical meristems are likely to be present 11. in a twig of a plant possessing, 4 branches and 26 leaves

[NCERT]

(a) 26

(c) 5

- (d) 30
- A piece of wood having no vessels (trachea) must be 12. belong to [NCERT]
 - (a) Teak

(b) Mango

(c) Pine

- (d) Palm
- 13. A plant tissue, when stained, showed the presence of hemicellulose and pectin in cell wall of its cells. The tissue represents INCERTI
 - (a) Collenchyma
- (b) Sclerenchyma

(c) Xylem

- (d) Meristem
- 14. Fibres are likely to be absent in
- [NCERT]

[NCERT]

- (a) Secondary phloem (c) Primary phloem
- (b) Secondary Xylem (d) Leaves
- 15. When we peel the skin of a potato tuber, we remove

- (a) Periderm
- (b) Epidermis
- (c) Cuticle
- (d) Sapwood
- A vesselless piece of stem possessing prominent sieve tubes 16. would belong to [NCERT]
 - (a) Pinus

(b) Eucalyptus

(c) Grass

- (d) Trochodendron
- 17. Which one of the following cell types always divides by anticlinal cell division [NCERT]
 - (a) Fusiform initial cells
- (b) Root cap
- (c) Protoderm
- (d) Phellogen
- 18. What is the fate of primary xylem in a dicot root showing extensive secondary growth
 - (a) It is retained in the centre of the axis
 - (b) It gets crushed
 - (c) May or may not get crushed
 - (d) It gets surrounded by primary phloem

Critical Thinking

Objective Questions

- Match the following and choose the correct combination
 - (A) Endodermis
- (1) Companion cells
- (B) Stomata
- (2) Lenticels
- (C) Sieve tube
- (3) Palisade cells
- (D) Periderm
- (4) Passage cells
- (E) Mesophyll
- (5) Accessory cells
 - [Kerala PMT 2009]
- (a) A-4, B-5, C-2, D-1, E-3
- (b) A-5, B-3, C-1, D-2, E-4
- (c) A-4, B-5, C-1, D-2, E-3
- (d) A-2, B-5, C-3, D-4, E-1
- (e) A-4, B-2, C-5, D-3, E-1

- In woody dicotyledons, the arrangement of vessels is either diffuse porous or ring porous. Based on these data, which one of the following statements is correct [BHU 1994]
 - (a) Ring porous vessels are specialised and are used for conducting more water for a shorter period only, when tyloses occur early in the vessels
 - (b) Although diffuse porous vessels are not so specialized as ring porous vessels, they conduct more water at all periods and through new xylem vessels added gradually during development
 - (c) Diffuse porous vessels carry more water and also faster because of a greater number of small vessels having greater capillary force
 - (d) Ring porous vessels conduct more water as they are formed early during development, when the need for water is great
- The quiescent centre in root meristem serves as a

[AIIMS 2003]

- (a) Site for storage of food, which is utilized during maturation
- (b) Reservoir of growth hormones
- (c) Reserve for replenishment of damaged cells of the
- (d) Region for absorption of water
- For a successful graft, the adhesion between stock and scion is a must. Which one of the following is the earliest event [CBSE PMT 1990] towards a good graft
 - (a) Production of plasmodesmata in the cells at the interface of stock and scion
 - (b) Coordinated differentiation of vascular tissue between the stock and scion
 - (c) Regeneration of cortex and epidermis over the union of stock and scion
 - (d) Production of callus tissue between the cells of stock
- If there is more than one tunica layer in a stem apex, which 5. among the following is most likely to happen
 - (a) All the layers will develop into epidermal cells
 - (b) Only the outer layer will develop into epidermal cells
 - (c) All the layers will develop into cortex
 - (d) Inner layer develops into cortex
- 6. Water containing cavities in vascular bundles are found in

[NCERT; CBSE PMT (Pre.) 2012]

- (a) Sunflower
- (b) Maize
- (c) Cycas
- (d) Pinus
- A nail is driven into the trunk of a 30 year old tree at a point 7. 1 meter above the soil level. The tree grows in height at the rate of 0.5 meters a year. After three years, the nail will be

[Kerala PMT 2004]

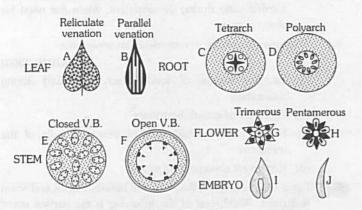

- (a) 1 meter above the soil (b) 1.5 meter above the soil
- (c) 2 meters above the soil (d) 2.5 meters above the soil
- (e) 3 meters above the soil level

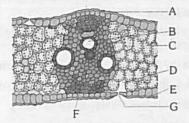

8. Grafting is not possible in monocots because they

[BHU 1995; MP PMT 1996; AFMC 2010]

- (a) Have scattered vascular bundles
- (b) Have parallel venation
- (c) Are herbaceous
- (d) Lack cambium
- 9. Trees at sea do not have annual rings because
 - (a) Soil is sandy
 - (b) There is climatic variation
 - (c) There is no marked climatic variation
 - (d) There is enough moisture in the atmosphere
- 10. See the following figures and identify the characters of Dicot and Monocot respectively [NCERT]

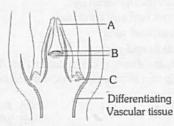

- (a) B, C, F, H, I; and A, D, E, G, J
- (b) A, C, E, G, I; and B, D, F, H, J
- (c) A, D, F, H, I; and B, C, E, G, J
- (d) A, C, F, H, I; and B, D, E, G, J
- 11. The following diagram shows the T.S. of monocot leaf, certain parts have been indicated by alphabets. Select the option in which A, B, C, D, E, F and G have been correctly matched with the parts which they indicate [NCERT]

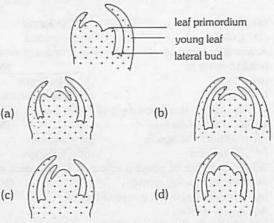

- (a) A Adaxial epidermis, B Xylem, C Stoma, D Substomatal cavity, E – Abaxial epidermis, F – Phloem, G – Mesophyll
- (b) A Adaxial epidermis, B phloem, C Mesophyll, D Sub-stomatal cavity, E – Abaxial epidermis, F – Xylem, G – Stoma
- (c) A Abaxial epidermis, B Xylem, C Mesophyll, D Sub-stomatal cavity, E – Adaxial epidermis, F – Phloem, G – Stoma
- (d) A Adaxial epidermis, B Xylem, C Mesophyll, D –
 Sub-stomatal cavity, E Abaxial epidermis, F –
 Phloem, G Stoma

 Identify the following points A, B and C in the given diagram [NCERT]

- (a) A Root hair primordium, B Root apical meristem, C– Terminal bud
- (b) A Root hair primordium, B Root apical meristem, C – Axillary bud
- (c) A Leaf primordium, B Shoot apical meristem, C Apical bud
- (d) A Leaf primordium, B Shoot apical meristem, C Axillary bud
- 13. The following diagram opposite illustrates a longitudinal section through a shoot apex. Which of the figures given below shows the correct appearance of this shoot apex at the formation of the next leaf primordium [NCERT]

- 14. A few drops of sap were collected by cutting across a plant stem by a suitable method. The sap was tested chemically. Which one of the following test results indicated that it is phloem sap [NEET (Phase-II) 2016]
 - (a) Absence of sugar
- (b) Acidic
- (c) Alkaline
- (d) Low refractive index

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below :

- (a) If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true

1.	Assertion	:	All tissues lying inside vascular cambium are called as bark.
	Reason	:	Bark is made up of phellogen, phellem and phelloderm lying inside secondary phloem.
			[AIIMS 1994]
2.	Assertion	1	Stomata are absent in submerged hydrophytes.
	Reason	:	Respiration occurs by means of air chambers in submerged plants.
			[AIIMS 1997]
3.	Assertion	1	Cambium is a lateral meristem and cause growth in width.
	Reason	+	Cambium is made up of fusiform and ray initials in stem. [AIIMS 1998]
4.	Assertion	:	Higher plants have meristematic regions for indefinite growth.
	Reason	:	Higher plants have root and shoot apices. [AIIMS 1999]
5.	Assertion	:	In collateral vascular bundles phloem is situated towards inner side.
	Reason	:	In monocot stem, cambium is present.
			[AIIMS 2000]
6.	Assertion	:	Thick cuticle is mostly present in disease resistant plants.
	Reason	•	Disease causing agents cannot grow on cuticle and cannot invade the cuticle. [AIIMS 1997]
7.	Assertion	4	Quiescent centre is found in the centre of
	100		the root apex.
	Reason	:	It consists of actively dividing cells.
8.	Assertion	:	Sclerenchyma cells do not have plasmodesmata.
	Reason	:	The cell walls of some permanent tissues are heavily lignified. [KCET 2010]
9.	Assertion	:	Intercalary meristem increase length of plant like apical meristems.
	Reason	:	Intercalary meristem originates from the
			apical meristems.
10.	Assertion	:	Apical and intercalary meristems contribute to the growth in length, while the lateral
	В		meristems bring increase in girth in maize.
	Reason		Apical and intercalary meristems always increase the height of plants.
			[EAMCET 2009]
11.	Assertion	;	Xerophytic leaves may contain stomatal crypts or sunken stomata.
	Reason	:	Spongy parenchyma is more in xerophytic leaves.
12.	Assertion	:	Xylem and phloem are also called as leptome and hadrome respectively.
	Reason	:	Xylem and phloem form conducting tissue of the plant

The upper surface of the leaf is darker than

chloroplasts than palisade mesophyll cells.

contains

mesophyll

the lower surface.

Spongy

13.

Assertion :

Reason

14.	Assertion	:	Tyloses plug the tracheids and vessels.
	Reason		Tuloses are in growths of yulem cells

Assertion Cuticle is also present in lower epidermal region of the leaf.

The lower epidermis contains a large Reason number of stomata.

16. Assertion Bulliform cells are useful in the unrolling of

Reason Bulliform leaves store water.

17. Assertion In grasses and cereals, intercalary

meristems are not present.

Intercalary meristems form Reason permanent tissues.

Sapwood is less durable than the Assertion :

heartwood.

Reason Hollow tree trunks are due to

disappearance of sapwood.

19. Assertion Idioblasts are derived from parenchyma. Reason Secretory cells are modified parenchyma.

20. Assertion : Growth rings are also called as annual rings. Generally growth ring is formed in each year. Reason

Tissue (General)

- 3. (a) Companion cells are connected with sieve elements by complex plasmodesmata. The sieve tubes are syncytes and allow free diffusion of soluble organic substances. The callose also plays important role. Usually the perforations in the sieve plates are surrounded by callose. The callose is soluble and disappears when the solute is dilute so that the solute can pass from one cell to another cell through the pores.
- (a) This theory was proposed by Schmidt (1924). This
 theory recognizes only two zones in the apical
 meristems.
- (c) This concept was given by Hanstein (1870). According to this, there are 3 groups of initials in the shoot apex.
- 7. (d) Vessel is a long cylindrical tube like structure made of many cells, called vessel members, each with lignified walls and a large central cavity. Vessel members are interconnected through perforation in their common walls.
- (b) Idioblasts: Those parenchymatous cells in which waste products e.g., gum, resin, sugar, starch is accumulated.
- (b) Collenchyma is never lignified but may possess simple pits.
- 14. (d) The walls of vessels are lignified and hard and not very thick. Sieve tubes have thin cellulose walls.
- 16. (b) Albuminous cells: These cells are storage cells which are found in pteridophytes and gymnosperms stem, they store minerals as well as starch.
- 17. (b) Technically, wood is secondary xylem formed by vascular cambium during secondary growth.

- 21. (a) Internal or intraxylary phloem: It originates from procambium and is primary phloem which occurs on inner side of primary xylem. It is primary anamolous structure. e.g., Members of Apocynaceae, Solanaceae.
- 23. (c) Cambium represents lateral meristem of plant which has actively dividing cells.
- 24. (d) In sieve tubes, nucleus is present only in young stage and without nuclei at maturity.
- 25. (b) It is a secondary permanent tissue developed from cork cambium (phellogen) by periclinal division in the extra stellar region.
- 26. (a) The cells of collenchyma contain protoplasm and are living without intercellular spaces. When sclerenchyma consist of thick-walled dead cells. In the beginning the cells are living and have protoplasm but due to deposition of impermeable secondary walls (lignin) they become dead, thick and hard.
- (b) They posses hard and extremely thick secondary walls due to uniform deposition of lignin.
- 28. (d) This theory was proposed by Schmidt (1924). According to this theory, shoot apex consists of two distinct zones – (1) Tunica (2) Corpus.
- (b) Tyloses are balloon like structures develop from xylem parenchyma.
- 31. (a) Lateral meristems occur laterally in the axis, parallel to the sides of stems and roots. The cambium of vascular bundles (fascicular, interfascicular and extrastelar cambium) and the cork cambium (phellogen) belongs to this category.
- 32. (c) Latex vessels found in Poppy (Papaver).
- 36. (d) In collenchyma cell walls show localized thickenings due to presence of approximately 45% pectin, 35% hemicellulose and 20% cellulose.
- 37. (b) Cystolith: In the epidermal cells of Ficus bengalensis leaves, the crystals of CaCO₃ accumulate in a grape manner, called as cystolith.
- 38. (a) The term xylem was introduced by Nageli (1858). Xylem is a conducting tissue. Xylem consists of Tracheids, Trachea (Xylem vessels), wood fibres and xylem parenchyma.
- 43. (c) Collenchyma tissue is made up of elongated cells with thickening at corners.
- (c) Chir is gymnosperm plant which belongs to family pinaceae of gymnosperm.
- 47. (b) Those fibres which are associated with wood or xylem have bordered pits are known as wood fibres.
- 48. (c) In endodermis (starch sheath) the inner and radial or transverse wall of endodermal cells have casparian strips of suberin.
- 51. (d) A group of initial cells, present at the subterminal region of the growing root tip, which is protected by a root cap is called root apical meristem or root apex.

- **52.** (a) Protoderm is the outermost layer of the apical meristem which develops into the epidermis or epidermal tissue system.
- 54. (d) Parenchymatous cells present between two vascular bundles give rise to interfascicular cambium after dedifferentiation.
- 56. (b) Saffranine stains lignified elements of the tissue.
- 58. (b) Haberlandt (1914) gave the term Leptome for soft walled conducting part of phloem (sieve-element).
- (a) Maize is a monocot so phloem parenchyma absent in maize.
- 63. (a) These meristems occur laterally in the axis, parallel to the sides of stems and roots. This meristem consists of initial which divide mainly in one plane (periclinal) and result increase in the diameter of an organ.
- **64.** (a) Parenchyma storage of food materials e.g., Carrot, Beet root etc.
- 65. (b) On the basis of origin, meristematic tissue can be classified into promeristem, primary meristem and secondary meristem.
- 66. (d) All are involved in primary growth of plant.
- 67. (a) Because such plants need much flexibility.
- 68. (a) The parenchymatous cells are isodiametric (all sides equal) and thinwalled.
- 71. (c) Metaxylem consist of two larger and rounded vessels situated on the sides with the pitted tracheids in between them.
- 72. (c) Sclereids is composed of sclerenchymatous cells, lignified walls and long tubular pits. The sclereids may be spherical, oval, cylindrical, T-shaped, dumbell-shaped or even stellate is size.
- 76. (c) Sieve tube formed by end to end fusion of cells and nuclei get degenerated at maturity.
- 77. (a) Haberlandt in 1890 classify the primary meristem at the apex of stem of three types: Protoderm, Procambium and Ground meristem. Haberlandt (1914) introduced the new terminology for meristematic zones derived from apical meristem. They are protoderm instead of dermatogen, ground meristem instead of periblem and procambium instead of plerome.
- 79. (d) A bladder like structure are formed during the secondary growth and blocks the continuity of the conducting system. It is known as tyloses which found in xylem cells and ray parenchyma.
- **86.** (c) Plane of division in tunica is anticlinal and in corpus it is periclinal.
- (d) Dermatogen is the outermost layer and it forms epidermis and epidermal tissue system.

- **89.** (a) Tracheids possess bordered pits. Maximum bordered pits are formed in gymnospermous tracheids (helps in conduction of water).
- **90.** (b) Eichhornia (water hycianth) is a hydrophytes. So root pocket present instead of root cap.
- 93. (d) Intercalary meristem is responsible for increase in length. This meristem is present at the base of internodes or at the base of leaves or at the base of nodes.
- **94.** (a) Trachieds are mainly found in gymnosperms while vessels are found in angiosperms.
- 95. (b) Root cap is absent in adventitious epiphytic roots of orchids, aquatic plants, parasites.
- 100. (a) Lignin is a deposition of cell wall.
- 101. (c) Companion cells are not found in pteridophytes and gymnosperms (Pinus) but are always present in angiosperms.
- 103. (d) A sieve tube is analogous to RBC, both being living but enucleated at maturity. A network of fibres of P₁ and P₂ protein is present in the central part of lumen of sieve tube which controls movement of materials and with callose, the sealing of pores after injury.
- 106. (a) Meristem posses the capacity of division. That is why plants keep growing in length whole life time.
- 108. (c) Xylem fibres are two lypes: libriform fibres (thickwalled with simple pits) and fibre tracheids (thin walled with reduced bordered pits).
- 111. (b) Macrosclereids or rod cells are rod shaped elongated sclereids usually found in the leaves, cortex of stem and outer seed coats.
- 112. (b) Lignification makes the xylem cells thick.
- 114. (a) The promeristem originates from embryo and therefore, called primordial or embryonic meristem.
- 117. (b) The opening in vessel element walls are called perforations, which may be simple perforation or multiple perforations.
- 119. (c) Meristematic tissue or meristem is a group of cells which has power of continuous division.
- 121. (a) Intercalary meristems are present mostly at the base of node (nodal region) (e.g., Mentha viridis, Mint), base of internode (e.g., stem of wheat, grasses), and the base of the leaf (e.g., Pinus).
- 122. (a) Because paddy is monocot plant.
- 123. (b) This is present away from apical meristem in primary permanent tissue. Some workers consider it as a part of apical meristem which is separated from it by means of primary permanent tissue.
- 124. (c) Chlorenchyma is the modification of parenchyma or specialized parenchyma.
- 126. (c) Promeristem is outer primary meristem.
- 128. (b) When wound is deep it is healed as follows healthy cells adjacent to the wound form a mass of parenchymatous cells called callus. This callus covers the wound entirely. Thus wound in healed.
- 130. (c) Lateral meristem present on the lateral sides. It divides only periclinally or radially and responsible for increase in girth or diameter of stem.

- 131. (c) Commercial jute fibres are obtained from phloem fibres.

 These are sclerenchymatous fibres but because of their presence in phloem they are called phloem fibres. They are used in making ropes.
- 132. (b) Pistia is a aquatic plant in which roots are not well developed.
- 133. (c) Most of the xylem cells have deposition of lignin on their cell wall.
- **134.** (c) Companion cells are found in angiosperms only. In gymnospermic plants albuminous cells are found in place of companion cells.
- **135.** (d) Because there is no variation in protoxylem and metaxylem in cells of secondary xylem.
- 137. (b) At the apex of roots some cells are not dividing, this region is called quiescent centre.
- 140. (b) Porous wood (In angiosperms) contains mainly vessels.
- 143. (a) Palisade parenchyma are elongated columnar cells without intercellular spaces. These have chloroplast in them and generally arranged in two layers.
- **145.** (b) Parenchyma containing air spaces is known as aerenchyma. It provides buoyancy to hydrophytes.
- 147. (a) Embryo has rapidly dividing cells.
- 149. (b) In tracheids if the entire surface is thickened leaving unthickened circular areas known as 'bordered pits'. The vessels lack the bordered pits.
- **151.** (a) Tunica is outermost layer and it becomes change into epidermis.
- 152. (d) Bryophytes grow by a single apical cell. Position of apical cells may either be strictly terminal or subterminal.
- 153. (d) Lenticels are some loosely arranged areas in the periderm. Lenticels are characteristics of woody stem. Lenticels are not found in leaves.
- 155. (c) According to histogen theory, apex of root is made up of dermatogen, periblem and pleurome.

The tissue system

- (a) Protostele term was given by Jeffrey. It is the simplest and most primitive type of stele in which central core of xylem surrounded by phloem.
- (b) Bicollateral vascular bundle is present in members of cucurbitaceae.
- (b) When phloem is surrounded by xylem on all sides, such V.B. are called amphivasal or leptocentric. These are found in Yucca and Dracaena.
- 8. (a) Root hair is outgrowth of epidermal cell.
- (d) Branching of root is endogenous. During the branching pericycle of root becomes meristematic and protrudes to outside.
- (b) In bicollateral vascular bundle, phloem is found on both the sides of xylem.
- (b) Periblem is the middle layer gives rise to cortex and endodermis.
- 14. (a) Waxy outermost lining, which is secreted by epidermis.
- (d) In the upper epidermis, there are some large cells found in groups, which are known as motor cells or bulliform cells.

- (c) Ground tissue system includes cortex, endoderm, pericycle and pith.
- 20. (a) Water stomata are usually present in leaves of aquatic
- (c) Raphides are found below the upper epidermis in Nerium.
- (a) Protoxylem surrounded by metaxylem are called mesarch.
- 23. (a) Inner wall of stomatal guard cell is thick and outer wall is thin. This type of structure helps in opening and closing of stomata.
- 24. (d) Because Nerium oleander is xerophytic plant and multiple epidermis is formed to check the loss of water from leaves.
- **25.** (b) When phloem is present on both external and internal sides of the xylem. *e.g.*, *Marsilea*, *Adiantum*.
- (a) Calcium oxalate substances deposited on the cuticle surface. Druse and Raphides (e.g., Pistia) are crystals.
- (c) In monocot roots a thick walled endodermal cells. Just outside the protoxylem. They help in passage of water from cortex to xylem.
- (b) Trabeculated endodermis is the characteristic feature of Selaginella.
- **32.** (c) A vascular bundle having the phloem strands on both outer and inner sides of xylem is called bicollatoral.
- **33.** (a) In amphivasal vascular bundle, phloem is surrounded by xylem e.g., *Dracaena*.
- 35. (c) Vascular tissue is well developed in xerophytes. These plants grows in areas where water supply is inadequate. Hence they have well developed root system and vasculature.
- 36. (b) When cambium is absent between xylem and phloem, it is said to be closed type.
- 39. (a) Sunken stomata found is xerophytic plants which is adaptation for decrease the rate of transpiration.
- 41. (d) Vascular cambium is formed secondarily from conjuctive parenchyma cells lying just below each phloem strand. The cells of pericycle lying out side the protoxylem also become meristematic to form part of strips of cambium.
- (a) Amphicribal (Hadrocentric): The xylem lies in the centre and remains completely surrounded by phloem. e.g., Ferns. (Selaginella).
- 44. (b) Free floating plants float freely upon the surface of water. Stomata present on upper epidermis. e.g., Wolffia, Lemna, Pistia etc.
- 46. (b) Dorsiventral leaves are found in dicots. In dicots stomata are present in lower epidermis.
- 49. (d) The whole plant body is enclosed by water. Submerged plants (e.g., Hydrilla, Vallisneria, Potamogeton) do not have stomata.
- 50. (b) In roots thick walled endodermal cells are interrupted by thin walled cells just outside the protoxylem patches. These thin walled endodermal cells are called passage cells or transfusion cells.

Internal structure of root, stem and leaf

- (b) Velamen tissue is water-absorbing tissue which can absorb atmospheric humidity. It is present in aerial root of orchids.
- 4. (b) Endodermis is mostly single layered and is made up of parenchymatous barrel shaped compactly arranged cells. The inner and radial or transverse wall of enedodermal cells have casparian strips of suberin.
- 5. (d) In between upper and lower epidermis, there is present mesophyll tissue which is undifferentiated into palisade and spongy parenchyma, but all the cells are alike.
- 7. (b) In monocot root, Cambium is absent in the vasculature.
- 11. (b) Hypodermis is collenchymatous (green) in dicot stem and sclerenchymatous (non-green) in monocot stem.
- 12. (c) Kranz type anatomy occurs in both monocot leaves (e.g., Sugarcane, Maize and Sorghum etc.) and some dicot leaves (e.g., Amaranthus-edulis, Atriplex rosea etc).
- 13. (d) In dicots vascular bundles are 2 to 6.
- 18. (d) In stems, the protoxylem lies towards the centre (pith) and the metaxylem lies towards the periphery of the organ. This type of primary xylem is called endarch. In root, the protoxylem lies towards periphery and metaxylem lies towards the centre, such arrangement is called exarch.
- 25. (c) Conjoint: A vascular bundle having both xylem and phloem together, is called conjoint. Collateral: A vascular bundle in which the phloem lies towards outer side and xylem towards inner side, is called collateral e.g., Sunflower.
 Collateral bundle having a cambium between xylem and
 - phloem is said to be of the open type. e.g., Dicot stem.
- 28. (a) Pith is generally having thin walled parenchymatous cells, which help in storage.30. (a) In vascular bundles of Cucurbita (family-
- cucurbitaceae), phloem is present in two patches.

 31. (a) In monocot root large pith, made up of loosely arranged parenchymatous cells with abundant starch
- 39. (a) Palisade tissue are elongated columnar cells without intercellular spaces. These cells have chloroplasts. They take part in photosynthesis.

grains.

Secondary growth

- (d) At the initial stage of secondary growth, cambium forms a ring like structure known as cambium ring. This ring is present in stelar and cortical region both.
- (b) Cells of sapwood are alive and because of abundant pore spaces, movement of sap takes place through these tissues.
- (b) Alburnum is an outer light coloured zone called the sap wood which are physiologically active.
- (a) Cork cambium (phellogen) develops from outer layer of cortex. It produces secondary cortex (phelloderm) on inner side and cork (phellem) on outer side.
- (d) Cork cambium aries as a result of the tangential division of the outer cells of pericycle.

- 8. (d) Periderm: During secondary growth in dicot stems towards the outer side cork cambium produces cork outer side and secondary cortex to inner side. The three layers (Phellem, Phellogen, and phelloderm) collectively called as periderm.
- (c) Vascular bundles are scattered and cambium is absent in monocot stem.
- 13. (a) The extrastelar regions grow simultaneously. The growth of extrastelar region is initiated by the formation of cork cambium or phellogen.
- 16. (d) Annual rings are formed due to variation in climatic conditions of any region. Spring season and autumn season occur in temperate region, thus clear annual rings are formed.
- (b) The correct sequence from outerside towards inner side in a wood dicot stem is

Phellem \rightarrow secondary cortex \rightarrow Secondary phloem \rightarrow wood (D) (A) (C) (B)

- 18. (a) Growth rings (Annual rings) are distinct or sharply demarcated in the plants of temperate (cold) regions (as shimla).
- (d) Phellem, phellogen and phelloderm are collectively called periderm.
- 28. (a) Hydrophytes mean plant grow in water. Hydrophytes do not show secondary growth because the vascular cambium is absent.
- (b) Treacheary elements such as tracheids, vessels, fibres, sieve tubes formed by fusiform initials.
- (d) Because climatic variations (autumn and spring seasons) are absent in deserts.
- (b) All dead tissues lying outside the active cork cambium are collectively known as bark.
- 35. (b) Knots: When wounds around cells undergo rapid cell division, then wound is covered by cells but the wound is not completely healup, so in adult stem knots are established.
- 36. (a) Vascular cambium is a lateral meristem.
- (a) Heartwood (duramen) is a hard and dark wood which are physiologically inactive (almost dead).
- 52. (b) After actual falling of leaf, the scar is exposed to air, which develops a primary protective layer by deposition of lignin and suberin on their wall.
- 54. (a) During the secondary growth, centrally located xylem become nonfunctional due to deposition of tannins etc. the function of conduction of water and dissolved minerals from roots is now performed by outer younger rings of secondary xylem is called sap wood or alburnum.
- 58. (b) Vascular cambium forms phloem tissue outside. Food synthesisted in the leaves move to different parts of the plant through the phloem.
- 61. (b) Secondary xylem is made up of scalariform and pitted vessels, tracheids and sclerenchymatous fibres (wood fibres) along with xylem parenchyma.

- 64. (b) In Oak (Quercus suber) which yields bottle cork, the cavities of cork cells are filled with air which makes the cork light in weight. It also provides thermal insulating qualities.
- 65. (a) Lenticels are some loosely areas in the periderm. Lenticels are characteristics of woody stem. Lenticels helps in gaseous exchange and transpiration.
- 66. (b) Pore like small openings are present on bark of old
- 67. (d) Vascular cambium is made up of lateral meristem.

Critical Thinking Questions

- (c) Quiescent centre having low rate of cell division and acts as reservoir of active initials.
- (d) New cells form a mass of parenchymatous cells known as callus.
- (b) Because tunica shows only anticlinal division and it is responsible for surface growth.
- (b) Stem of maize has water containing cavities in vascular bundles.
- 7. (a) The nail will be 1 meter above the soil because when tree grows in height it will not effect the base level (Tree grows in height from the apical region).
- 8. (d) A new variety is produced by joining parts of two different plants (with the help of cambia) is called grafting. In monocots cambium is absent hence the parts of two different plants are unable to joint each other.
- (c) Because in sea shore area being isothermal zones, temperature is constant throughout the year, so their will be no annual ring formation.
- (c) Alkaline pH (7.8 8.0) is present in phloem sap where as xylem sap is acidic

Assertion and Reason

- (d) Bark consists of all tissues out side the vascular cambium. Phellem, phellogen and phelloderm constitute periderm.
- 2. (b) Stomata are absent in submerged hydrophytes. Air chambers help in gaseous exchange, O₂ liberated during photosynthesis is stored in these chambers and used in respiration, CO₂ released during respiration also remain in these chambers. CO₂ is used in photosynthesis.
- (b) Cambium is a lateral meristem. Its activity causes increase in width. It is composed of fusiform and ray initial.
- 4. (a) Higher plants have root and shoot apices where cells are in continuous state of division. Here they can grow indefinitely. Such regions are not found in animals.
- (d) In collateral vascular bundles phloem is situated towards outer side and xylem towards inner side and both are found on same radii, but in monocot stem vascular bundle are closed, i.e., cambium is absent.

- (a) Disease resistant plants possess thick cuticle. Infectious organisms can not grow or invade cuticle.
- 7. (c) Quiescent centre is found in the centre of the root apex. Cell divisions are very few in the quiescent centre as there is very little synthesis of new proteins, RNAs and DNA. Quiescent centre may function as reserve meristem.
- 8. (a)
- 9. (a) Intercalary meristems are intercalated in-between the permanent tissues. The activities of these meristems also add to the length of the plant or its organs. They originate from the apical meristems when their portions get detached due to the growth of the organs. For example, in the grasses when the internodes complete their elongation, some cells at the base retain their meristematic activity and function as intercalary meristems. They lie just above the node.
- 10. (d) Apical and intercalary meristems always increase in the height of plant and lateral meristem is responsible for secondary growth (increase in girth) but secondary growth doesn't occur is monocots.
- 11. (c) In xerophytic leaves, spongy parenchyma is reduced. Palisade parenchyma may occur on both upper and lower sides with spongy parenchyma sandwitched between the two, e.g., Nerium. In Nerium or Oleander, the lower surface bears deep depressions called crypts (stomatal crypts). The crypts possess a number of cutinised hair and stomata. In other xerophytic plants, stomata occur individually and are sunken below the surface due to their being overtopped by accessory or subsidiary cells.
- 12. (e) Phloem transports organic food inside the body of the plant. Xylem performs the function of transport of water or sap inside the plant. Thus they form the conducting elements in the plant. Haberlandt used the term leptome for phloem and hadrome for xylem.
- 13. (a) The palisade mesophyll lies below the upper epidermis. The spongy parenchyma or spongy mesophyll lies between the lower epidermis and the palisade parenchyma. The spongy mesophyll cells contain chloroplasts but fewer than present in the palisade parenchyma. As the chloroplasts are more abundant in the compact palisade mesophyll cells than the loosely arranged mesophyll cells, the upper surface of the leaf appears deeper green as compared to the lower surface.
- 14. (c) The tracheids and vessels of the heart wood get plugged by in growth of the adjacent parenchyma cells into their cavities through the pits. These in growths are called tyloses. Ultimately, the parenchyma cells become lignified and dead.

- 15. (b) A distinct layer of cuticle is present in the lower epidermis. The cuticle is, however, less developed than at the upper epidermis. The lower epidermis contains a large number of pores called stomata or stomates. They lead internally into substomatal cavities.
- 16. (b) In isobilateral leaves, the upper epidermis contains specialized cells, i.e., bulliform or motor cells. They are highly vacuolate and can store water, if available. However, in case of water deficiency the bulliform cells lose water and become flaccid. As a result the leaf gets rolled upto reduce the exposed surface, the bulliform cells are also useful in the unrolling of leaf during its development.
- 17. (e) Intercalary meristems are intercalated in between the permanent tissues. They may be present either at the base of the internode as in the stems of various grasses and wheat; or at the base of the leaf as in Pinus; or at the base of a node as in mint (Mentha viridis). Usually the intercalary meristems differ from other meristems in that they ultimately get fully used up in the formation of permanent tissues.
- 18. (c) Various types of plant products like oils, resins, gums and tanins are deposited in the cells of the heartwood. They are antiseptic. The heartwood is, therefore, stronger and more durable than the sapwood. It is, however, liable to be attacked by wood rotting fungi. Hollow tree trunks are due to their activity. Sapwood (outer light coloured wood) is less durable because it is susceptible to attack by pathogens and insects.
- 19. (b) Secretory cells are specialized parenchyma cells that produce nectar, oil, etc. Idioblasts are specialized nongreen large-sized parenchyma cells which possess inclusions or ingredients like tannins, oils, crystals, etc.
- 20. (a) The activity of the cambium is commonly periodic in the temperate regions and the xylem produced during one growth period constitutes a growth layer. In transverse sections of stems and roots, autumn wood (summer wood) and spring wood appear in the form of distinct concentric circles known as the annual rings. Spring wood circle and autumn wood circle constitute an annual rings. Like this, year after year, such rings in the oldest part of the tree corresponds to its age.

- (c) Collenchyma tissue is elastic, extensible and have capacity to expand.
- (a) A zone of inactive cells is present in the central part of the root apex called quiescent centre.
- (d) Diffuse porous wood (primitive): Vessels of same size are uniformly distributed throughout the growth or annual ring. e.g., Pyrus, Azadirachta, Eucalyptus, Magnifera sp., Betula.
- 7. (c) The stems of hydrophytic plants are soft and weak, spongy which can bend easily in each and every direction because mechanical tissue is either absent or reduced and conductive tissue is poorly developed.
- (d) Mechanical strength to hypocotyl of seedling is provided by epidermis and collenchyma tissues.
- 10. (c) Bicollateral: In such vascular bundles there are two patches of phloem one on each side of xylem. In such a vascular bundles there are two strips of cambium one on each side of xylem. Cucurbitaceae (e.g., Cucurbita).
- 12. (b) In a completely mature vascular bundle a schizolysigenous cavity is formed by disintegration of protoxylem. These cavities are filled with water.
- 14. (b) Spring wood + Autumn wood of a year constitute annual ring. Spring and Autumn wood is the part of secondary xylem formed during spring and autumn. The amount of wood is affected by the activity of cambium.
- 15. (b) The outer young and functional part of xylem is called sap wood. The functions of conduction of water and dissolved mineral from roots is now performed by outer younger rings of secondary xylem which constitute the sapwood.
- 16. (b) According to the tunica corpus theory epidermis is derived from outer layer of tunica and the remaining tissues are derived from remaining layer of tunica and entire corpus.
- 18. (a) In dicotyledonous roots, a well developed pericycle lies below endodermis which gives rise to lateral roots, part of vascular cambium and whole cork cambium. Pericycle functions as the site of lateral root initiation.

Animal Tissues

A tissue may be defined as a group of one or more types of cells having a similar origin and specialized for a specific function or functions along with the intercellular material.

Branch of biology dealing with the study of tissue is called histology. The term 'tissue' was introduced by *Bichat* and also known as 'Father of histology'. *Mayer* coined the term 'histology' and the founder of histology is *Marcello Malpighi*. Following types of tissues are found in animals:

Epithelial Tissue

An epithelium is a tissue composed of one or more layers of cells that cover the body surface and lines its various cavities. It serves for protection, secretion and excretion. The word 'epithelium' (G. epi = upon, thele = nipple) was introduced by Ruysch. They are located on the outer surfaces of organs, including the skin. They form the linings of tracts, cavities and vessels. Epithelial tissue evolved first in animal kingdom. It originate from all the three primary germ layers.

Structure

Cells are arranged in one or more layers, cells are compactly arranged and there is no inter cellular matrix between them. Neighbouring cells are held together by intercellular junctional complexes like desmosomes, tight junctions, interdigitations etc. The cells of lowermost layers always rest on a non living basement membrane or basal lamina. Basement membrane is made up of no cell product of epithelial tissue. It is formed of mucopolysaccharides, glycoprotein and collagen or reticular fibres. Blood vessels are absent in the epithelial tissues. However, nerve endings may penetrate the epithelium. It possesses very high capacity of renewal (mitotic cell division). The following types of modifications and junctions are found in the plasma membrane of adjacent epithelial cells to keep the cells together.

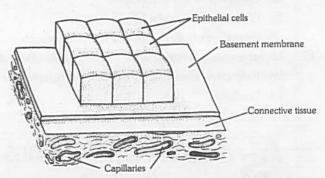

Fig: 2.3-1 Diagram to show an epithelium with its basement membrane resting upon underlying connective tissue

Microvilli: These are simple and minute cytoplasmic processes arising from free exposed surfaces of the cell. They absorb material, e.g. Intestine.

Stereocilia : These are non-motile cytoplasmic processes. e.g. Epididymis, vas deference.

Kinocilia : It is contractile motile fibrous processes arising from basal granules. e.g. Oviduct, Fallopian tube.

Tight junctions (Zona occludens): At certain places the plasma membranes of adjacent cells are tightly packed or even fused together. e.g. Brain.

Desmosomes : Desmosome is present in epithelial tissue. They consist of thickened area and several fine tonofibrils extending from each plasma membrane into cytoplasm of respective cells. Macula adherens is a kind of desmosome. e.g. Vagina, Urinary bladder.

Gap junction : At place, the adjacent cells form ion-rich gap junctions for intercellular communication and chemical exchange. These junctions probably do not provide physical support.

Interdigitations: These are interwoven finger-like processes of plasma membranes of adjacent cells.

UNIVERSAL BOOK DEPOT 1960

Intercellular bridges: These are minute projections that arise from adjacent cell membranes. The intercellular bridges make contact with one another.

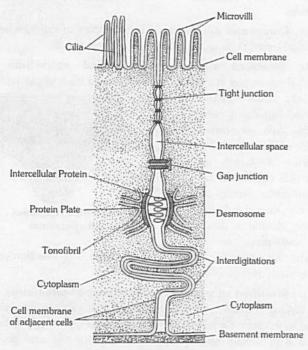

Fig: 2.3-2 Intercellular junctions between two adjacent epithelial cells

Functions

Epithelial tissues have a wide spread distribution throughout the body and serve several important functions –

- (1) Generalized protection is the most important function of membranous epithelium. It is the relatively tough and impermeable epithelial covering of the skin that protects the body from mechanical and chemical injury and also from invading bacteria and other disease causing micro-organisms.
- (2) Epithelial structures specialized for sensory functions are found in the skin, nose, eye and ear.
- (3) Glandular epithelium is specialized for secretory activity, secretory products include hormones, mucous, digestive juices and sweat.
- (4) The epithelium lining of the gut and respiratory tracts allows the absorption of nutrients from the gut.
- (5) It is the specialized epithelial lining of kidney tubules that makes the excretion and concentration of excretory products in the urine.
- (6) Ciliated epithelium moves fluid, mucus and other materials in the organs it lines.
- (7) Germinal epithelium of the seminiferous tubules and ovaries produces spermatozoa and ova respectively.
- (8) The ability of epithelium to regenerate quickly helps in the healing of wounds.
- (9) Pigmented epithelium of retina darkens the cavity of eyeball.

- (10) The epithelia check the absorption of harmful or unnecessary materials.
- (11) Epithelium of alveoli of the lungs brings about exchange of gases between blood and air.
- (12) Epithelium also produce exoskeletal structures such as scales, feathers, hair, nail, claws, horns and hoofs.

Types of epithelial tissue

Mainly based on the location and functions of tissue it is of following types -

- Simple epithelium: It simple in structure and basically formed by single layer cells.
- (i) Simple squamous epithelium: It consists of only one layer of flat, scale like cells, usually polygonal cells which are closely fitted together like the tiles of a mosaic. It is also known as pavement epithelium. e.g., It forms lining of blood vessels, lymph vessel, heart, peritoneum, pleura, Bowman's capsule, thin segment of loop of Henle and lung alveoli.

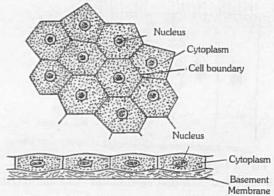

Fig: 2.3-3 Simple squamous epithelium

(ii) Simple cuboidal epithelium: The simple cuboidal epithelium is composed of one layer of cuboidal shaped cells resting on a basement membrane. The nuclei are situated centrally. e.g. the cuboidal epithelium is present in the small salivary and pancreatic ducts, thyroid vesicles, parts of membranous labyrinth, PCT, DCT, ovaries, seminiferous tubules of testes, ciliary bodies, choroid, iris of eyes, thin bronchioles and sweat gland of mammalian skin.

Fig: 2.3-4 Simple cuboidal epithelium

(iii) Simple columnar epithelium: It consists of a single layer cells, many of which have modified structure. Three common modifications are goblet, cilia and microvilli. Simple columnar epithelium is present in the stomach and intestine e.g. inner lining of gall bladder and bile duct. It also occurs in the gastric gland, intestinal glands, pancreatic lobules.

422 Animal Tissues

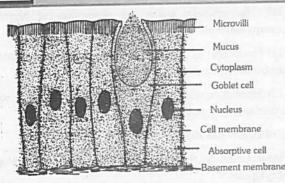

Fig: 2.3-5 Simple columnar epithelium

- (iv) Simple ciliated epithelium: It bears numerous delicate hair like outgrowths called cilia arising from basal granules which helps to create a current to transport the materials. The ciliated epithelium is of two types:
- (a) Ciliated columnar epithelium: It lines respiratory tract (Lower end of bronchi), fallopian tubes (oviducts), ventricles of brain (ependyma), central canal of spinal cord, tympanic cavity.

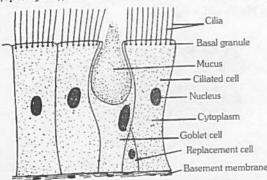

Fig: 2.3-6 Simple columnar ciliated epithelium

- (b) Ciliated cuboidal epithelium: It occurs in certain parts of nephrons of the kidneys.
- (v) Pseudostratified epithelium: It always consist of single layer of irregularly shaped columnar cells, touches the basement membrane. The long cells have oval nuclei however,

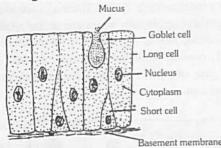

Fig: 2.3-7 Pseudostratified epithelium

Short cells have rounded nuclei although epithelium is one cell thick, but it gives the appearance of a stratified epithelium, hence it is called pseudostratified epithelium. Mucus secreting goblet cells are numerous and cilia are present. It is of two types —

- (a) Pseudostratified columnar ciliated epithelium: It is found in the lining of trachea and bronchi (Upper).
- (b) Pseudostratified columnar epithelium: It is found in certain segments of human male urethra and parotid salivary gland, vasa deferentia and epididymis.

- (c) Stratified squamous epithelium: The cells in the deepest layer are columnar or cuboidal with oval nuclei. It is called germinative layer. The cells of this layer divide by mitosis to form new cells.
- (2) Compound epithelium: It is complex in structure and basically formed by two or more than two layers of cells.
- (i) Stratified squamous keratinised epithelium :
 Stratified squamous epithelium is characterized by multiple layers

of cells with typical flattened squamous cells at the free or outer surface of the sheet. The presence of keratin in these cells contributes to the protective qualities of skin covering the body surface. Keratin is dead and waterproof so it

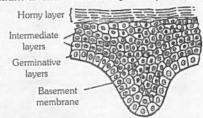

Fig: 2.3-8 Stratified squamous Keratinised epithelium

protects the underlying tissues from abrasion and infection e.g. epidermis of the skin of land vertebrates.

(ii) Stratified squamous non keratinised epithelium: Its free surface is moist, and the outer epithelial cells, unlike those found in the skin, do not contain keratin. This type of epithelium serves a protective function. It is found lining the oral cavity (buccal cavity), pharynx, oesophagus, anal canal, lowerpart of urethra, vocal cords, vagina, cervix (lower part of uterus) and cornea of eyes.

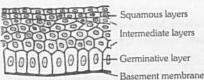

Fig: 2.3-9 Stratified squamous non keratinised epithelium

- (iii) Stratified cuboidal epithelium: It consists of two or more rows of low cuboidal-shaped cells which are arranged randomly over a basement membrane. It is found in the sweat gland ducts, larger salivary and pancreatic ducts.
- (iv) Stratified columnar epithelium: It is protective epithelium having multiple layers of columnar cells, only the most superficial cells are truly columnar in appearance. Epithelium of this type is rare. It is found in male urethra and in the mucous layer near the anus. It also lines mammary gland ducts and epiglottis.

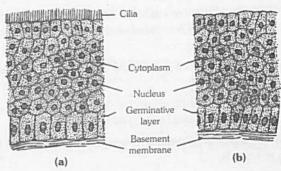

Fig : 2.3-10 (a) Stratified columnar ciliated epithelium (b) Stratified columnar epithelium

- (v) **Stratified columnar ciliated epithelium**: It lines the larynx and upper part of the soft palate.
- (3) **Specialized epithelium :** This type of epithelium are specialized to perform specific activity hence, specialized in structure also. They are as follows –
- (i) Transitional epithelium (Urothelium): It is often ten or more layers thick. It lacks germinative layer, basement membrane. Stratified transitional epithelium is typically found in the body areas such as the wall of urinary bladder, ureter and renal pelvis. It is located in all the hollow viscera subjected to stress and protects organ wall from tearing.
- (ii) Neurosensory epithelium: Olfactory mucosa, called Schneiderian membrane, lining of internal nares, retina of eyes and epithelial covering of tongue containing taste buds are examples of neurosensory epithelia. The sensory cells bear, at their free ends, slender "sensory hairs" to receive specific stimuli. Basely, these cells are connected, by means of synapses, with fine fibrils of sensory nerves.
- (iii) **Pigmented epithelium :** The epithelial cells of the basal layer of retina contain pigment. Hence, this layer is often referred to as a pigmented epithelium. e.g. Pigmented layer of retina, iris and skin.
- (iv) **Germinal epithelium :** Specialized cuboidal cells capable of producing gametes as found in gonads. Germinal epithelium produces gametes e.g., ova (Female gametes) and sperms (Male gametes)

Glands

Glandular epithelium are specialized for secretory activity. A cell, tissue or organ which secretes a useful chemical material is known as gland. Glands are made up of cuboidal epithelial cells which are more secretory. All glands arise as folding of epithelia. The golgi body in gland cells are larger and more secretory. Most of the glands of body are merocrine types. It originate from all three germinal layers. (ecto, meso and endoderm). Liver is the largest gland of the body and lined by glandular epithelium.

Types of glands

(A) On the basis of number of cells

- (1) Unicellular gland: It consist of unicellular gland cells which are called as goblet cells or chalice cells. They secrete mucous and found in mucosa of intestine and stomach. Mucous lubricates the food for easy peristalsis. Their life span is about 2–3 days.
- (2) Multicellular gland: It consist of many cells and are generally located in underlying connective tissue e.g. gastric and intestinal glands.

(B) On the basis of presence or absence of ducts

- (1) Exocrine gland: These are those glands which discharge their secretory products into ducts. It is also called ducted glands or glands of external secretion. e.g. Salivary glands, Mammary glands and Tear glands.
- (2) **Endocrine gland**: They are often called ductless gland, because they discharge their secretory products (hormones) directly into the blood. e.g. Pituitary gland, thyroid, parathyroid and adrenal glands.

(3) Heterocrine gland: These are those glands which are partly endocrine and partly exocrine in function. e.g. Pancreas.

Structural classification of exocrine glands

Multicellular exocrine glands are classified by structure, using the shape of their ducts and the complexity (branching) of their ducts system as distinguishing characteristics. Shape include tubular and alveolar (Sac like). Simple exocrine glands e.g. intestinal glands, mammalian sweat glands, cutaneous glands of frog etc. have only one duct leading to surface. Compound exocrine glands have two or more ducts e.g. liver, salivary glands etc.

Table: 2.3-1

Туре	Example	
Simple tubular	Intestinal glands, crypts of Lieberkuhn in ileum.	
Simple coiled tubular	Sweat glands in man	
Simple branched tubular	Gastric (stomach) gland, and Uterine gland.	
Simple alveolar	Mucous gland in skin of frog, Poison gland of toad and seminal vesicle.	
Simple branched alveolar	Sebaceous glands	
Compound tubular	Brunner's gland, bulbourethral gland and liver.	
Compound alveolar	Sublingual and submandibular salivary gland	
Compound tubulo alveolar	Parotid salivary glands, Mammar gland and Pancreas.	

Classification of glands on the basis of their mode of secretion

- (1) Apocrine gland: Apocrine glands collect their secretory products near the apex or tip, of the cell and then release it into a duct by pinching off the distended end. This process results in some loss of cytoplasm and damage to the cell. e.g. Mammary glands. (Modified sweat gland)
- (2) Holocrine gland: Holocrine glands collect their secretory products inside the cell and then rupture completely to release it. These cells self destruct to complete their functions. e.g. Sebaceous glands. In case of rabbit sebaceous glands are found in dermis of skin. Pineal body and thymus can also be considered as holocrine gland.
- (3) Merocrine gland: Merocrine glands (Eccrine or Epicrine glands) discharge their secretory product directly through the cell or plasma membrane, without injury to the cell wall and without loss of cytoplasm. e.g. Sweat glands, exocrine region of vertebrate pancreas, salivary glands and intestinal glands etc.

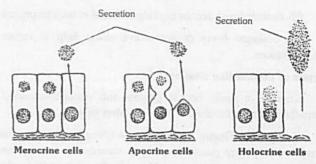

Fig: 2.3-11 Types of glands regarding the mode of secretion

424 Animal Tissues

Classification of glands on the basis of nature of product

- Mucous gland: Secret slimy mucous e.g. goblet cells, palatine gland, gland of uterus, some gastric gland and gland of colon.
- (2) Serous gland: Produce watery secretion. e.g. pancreas, parotid, salivary gland, sweat gland and intestinal gland.
- (3) Seromucous gland: Secrete mixed liquid. e.g. Most gastric gland, sublingual, submaxillary salivary gland, pancreas.
- (4) Cytogenic gland: They produce cells e.g. Testis and ovary.

Connective tissue

It connects and supports all the other tissues, the intercellular element predominating. The cellular element is usually scanty. In function this tissue may be mechanical, nutritive and defensive. It is a tissue made up of matrix (abundant intercellular substance or ground substance) and living cells that connects and support different tissues. All connective tissues in the body are formed by mesoderm.

Structure

There are large intercellular spaces between the cells. Intercellular spaces are filled with large amount of extracellular materials formed of insoluble protein fibres lying in an amorphous, transparent ground substance called matrix. Ageing of an animal body is associated with deterioration in its connective tissues.

Functions

- (1) Their chief function is to bind other tissues together in the organs.
 - (2) Certain connective tissues such as adipose tissues store fat.
- (3) Skeletal connective tissues like bones and cartilages provide the body with a supporting skeletal frame work.
- (4) Fluid connective tissues such as blood and lymph transport various materials in the body.
- (5) Plasma cells synthesize antibodies, viz., macrophages. Lymphocytes ingest cell debris, harmful bacteria and foreign matter. Thus these cells of connective tissues are protective in function.
- (6) The jelly-like ground substance of connective tissues acts as shock absorber around some organs such as eye balls and kidneys.
 - (7) The bone marrow produces blood cells.
 - (8) Areolar tissue acts as packing material in various organs.
- (9) Collagen fibres of connective tissue help in repair of injured tissues.

Types of connective tissues

Connective tissue proper possess soft viscous semisolid or semi-fluid matrix. It is divided into following types :

(1) Areolar Tissue: Areolar tissue is loose connective tissue, possess transparent gelatinous, highly vascular and sticky matrix which have variety of cells and fibres. It allows movement of part

connected by it (Muscle and their compound). Areolar tissue mainly consist of different types of cells and fibres.

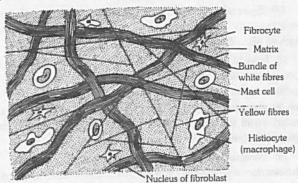

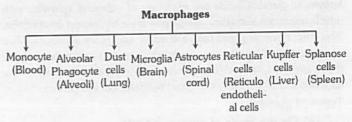

Fig: 2.3-12 Areolar connective tissue

(i) Cells of areolar tissue: It has following types -

Fibroblast : These are the most abundant cells, produces fibres, called as fibroblasts in their young active phase and fibrocytes when old and inactive. It synthesize proteins (Collagen, elastin and reticulin). These are undifferentiated mesenchyme stem cells, capable to give rise other cells of connective tissue. Collagen and elastin are formed by fibroblasts.

Histiocytes or Macrophages or Clasmatocytes: These are polymorphic cells. These are amoeboid cells and are main phagocytes of connective tissue. They are having most active lysosomes and phagocytise dead cells and pathogens. Macrophages remove the dead and damaged cells and clean the body so called scavenger cell. All types of macrophages take part in phagocytosis.

Reticular cells : Present only in the reticular tissue and stellate in appearance. Infact they are modified fibroblast producing reticular fibres.

Mast cells: Mast cells were discovered by Paul Echrlich. They are large, irregular ovoid cells found in areolar tissue, and their number increases during allergies. It produces or secretes histamine (vasodilator), serotonin (vasoconstrictor) and heparin (anticoagulant). Histamine dilate the blood vessels in allergic and inflammatory conditions. Heparin checks the clotting of blood inside the blood vessels. Serotonin act as vasoconstrictor to arrest bleeding.

Lymphocytes: These are the smallest, less numerous and spherical or ovoid cells resembling lymphocytes of blood and lymph. These actively move about by pseudopodia. Their function is to form and carry antibodies. That is why, they are seen in large numbers at sites of inflammation.

Plasma cells (Plasmacytes): These are usually small and rounded, superficially resembling lymphocytes but are sluggishly amoeboid and short-lived (only 2 or 3 days). These are the most potential antibody-forming cells of body presumably, mature lymphocytes (B-lymphocytes form antibody) transform into plasma cells or proliferate to form plasma cells. Plasma cells are also known as cart wheel cells.

Fat or Adipose cells (Adipocytes or Lipocytes): A few, large and spherical cells occur in areolar tissue, singly or in clusters around small blood vessels. Each cell contains a large globule of fat surrounded by a thin peripheral layer of cytoplasm having a nucleus.

Eosinophils: These cells closely resemble the eosinophilic leucocytes of blood. These probably play a phagocytic role in inflammatory and allergic reactions.

Chromatophores: These are pigment cell present in specialised areas such as skin and eye. They are much branched and packed with pigment granules. They are stellate (Star like) cells, which are phagocytic in nature. They phagocytes melanin producing cells and retain melanin hence they provide colour to the skin and other organs. Melanin is black pigment which protects body from ultraviolet rays of sun.

Mesenchyme cells: These are reserve undifferentiated cell which can be transformed into other types of cells when needed.

(ii) **Fibres of areolar tissue :** These are made up with protein and non living structures of protein produced by fibroblasts and present in matrix of connective tissue and are of three types –

Collagenous fibres: These are the most abundant fibrous element of areolar and other connective tissues. These are long, unbranched fibres of a soluble and shining collagen protein (tropo collagen). These fibres are more strengthful and provide maximum tensile strength. These are colourless and hyaline, yet called white fibres to distinguish them from yellow elastin fibres. Collagen protein is the most abundant protein of the body constitutes 25% the total body protein. Collagen fibre can be stained by eosin. When collagen fibres are removed from the areolar tissue they become loose and elastic. e.g. Bone, Cartilage, Ligement and tendon.

Yellow elastin fibres: Formed of elastin protein, these fibres are less numerous, thinner, branched, anastomosing, and of a pale yellow colour. These are very elastic and remain stretched due to tension in the areolar tissue, when broken in teased preparations, these coil and curl like tense wires. Elastin is probably the most resistant of all body proteins to chemical changes. Thousands of years old 'mummies' still have their arteries intact due to well-preserved elastin fibres. They are the orceinophilic i.e. stained by orcein.

Reticulin fibres: These are delicate, freely branching and inelastic fibres of reticulin protein, found interwoven, to form networks. These are very abundant in embryos, new born babies and in healing and regenerating wounds. In areolar tissues of adults, these are mostly replaced by collagen fibres, but remain abundant in lymphoid and blood forming tissues and in the stroma of pancreas, liver etc. They are stained with *AgBr* and *AgNO*₃ hence are called Argentophillic or Argyrophillic. On boiling collagen and reticular fibres both convert in glue.

- (2) White fibrous tissue (Dense connective tissue): It is modified form of areolar tissue. Only collagen fibres are present in the matrix and cells are mainly fibroblasts, present at the joints between skull bones and makes them immovable, also found in the dermis of higher mammals. It is of two types –
- (i) **Tendons**: A tendon is non-elastic but flexible tissue consisting of parallel bundles of collagenous fibres between which rows of fibroblasts are present. It joins the muscles to bones. It also form chordae tendinae which joins the cusps of atrioventricular valves of heart with the wall of ventricles.
- (ii) **Sheath**: In a sheath, the bundles of white fibres lie in a criss-cross manner. The fibroblasts are not in rows but are scattered in the areolae. The sheath form protective covering.

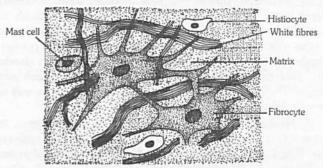

Fig: 2.3-13 White fibrous tissue

(3) Yellow fibrous tissue (Elastic connective tissue): The matrix is with numerous and closely packed yellow or elastin fibres which are similar to but thicker than those of areolar connective tissue. It is elastic and flexible. It forms wall of blood vessels, lungs, true vocal chords, trachea, capsule of spleen and bronchioles. It also forms sheet in ligaments. Ligaments is a modified yellow elastic fibrous tissue and connects bone to bone.

Fig: 2.3-14 Yellow fibrous tissue

(4) Adipose tissue: It is modified form of areolar tissue made up of specialized large spherical fat cells (below the skin) or adipocytes. Adipose tissue chiefly act as "Food reserves" or fat depots for storage and metabolism of lipids. Besides this, they also act as heat insulators and pressure, pull and push absorbers. Adipocytes are of two types:

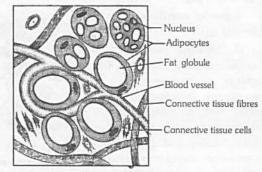

Fig: 2.3-15 Adipose connective tissue

- UNIVERSAL BOOK DEPOT 1960
- (i) Unilocular adipocyte (White adipose tissue):
 Common fat of body, having single large fat globule, maintain body temperature, found beneath skin subcutaneous fat panniculus adiposus, blubber of whales and elephants, hump of camel and tail of merino sheep, yellow bone marrow, around kidneys and blood vessels, mesentries, omenta and the fat bodies of frog.
- (ii) Multilocular adipocyte (Brown fat): Each multilocular adipocytes have several small fat globules, contain more number of mitochondria, found in rats and other rodents, polar bear, penguins, seal, walrus, in new born human babies and hibernating mammals (rats and other rodents). On oxidation it yields about 20 times more energy than ordinary fat. Brown colour is due to iron containing cytochrome pigment.
- (5) Reticular tissue: It is a modified form of areolar connective tissue characterized by the matrix which is fluidy in nature. The matrix contains large number of stellate-shaped reticular cells, each with a number of protoplasmic processes. Reticular tissue is found in spleen, thymus, tonsils, lymph glands, liver, bone-marrow, lamina propria of mucosa of stomach and intestine. The reticular cells act as phagocytes and form a part of defence system of the body.
- (6) Myeloid tissue: It is modification of reticular tissue. Its ground substance is plasma. It posses heavy network of reticular fibres. In active form the cells are myeloblasts. It is found in red bone marrow or haemopoietic tissue and fat reserve of yellow bone marrow.

Skeletal tissue

It provide support and surface for attachment of muscle. Skeletal connective tissue is mesodermal in origin and forms the frame work of body. It provide rigidity to body. These protect the various organ and help in locomotion. It is of three types: Cartilage, Bones, Notochord.

Cartilage

Cartilage is a solid but semi-rigid and flexible connective tissue. Cartilage is a nonvascular connective tissue, consisting of cells embeded in a resilent matrix of chondrin. Chondrin is a protein of cartilage. Regeneration of cartilage can occur from its peri-chondrium. Cartilage is said to be metabolically nearly inactive. In kids the cartilage cells show 2 types of growth.

- (1) Appositional or Perichondral or Secondary or Exogenous growth: It is due to deposition of matrix and division of chondrogenic cells of periphery. It leads to growth in thickness.
- (2) Endogenous or Interstitial growth: It is due to deposition of matrix and division in inner cells of cartilage. It leads to growth in size.

Types of cartilage: It is of following types –

(1) Hyaline cartilage: It is most primitive and glass like cartilage. Its matrix is transparent homogenous and pearly white or bluish green in colour, contain chondrin. It is slightly elastic and also known as articular cartilage because it forms the articular surface of

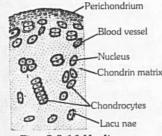

Fig: 2.3-16 Hyaline cartilage (section)

joints. Hyaline cartilage is found in trachea, larynx and bronchi, limb bones (called hyaline cap), sternum, in the hyoid apparatus nasal septum, ribs (sternal parts) larynx (cricoid, thyroid), nasal cartilage (nasal septum).

(2) Fibro cartilage (White fibrous cartilage) : In this

cartilage, the small amount of matrix of cartilage is packed with large number of bundles of thick white (collagen) fibres. So it is toughest and less flexible. It is found in intervertebral discs and acts as shock absorber. It is also found in pubic symphysis and helps in parturition (child birth). The intervertebral discs remain contracted when the body is active, but relaxed when the body is at rest. That

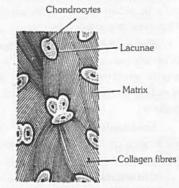

Fig: 2.3-17 Fibrocartilage White

is why, our body becomes a bit taller during sleep and after death.

- (3) Elastic cartilage (Yellow elastic cartilage) : In this
- cartilage, the matrix is packed with yellow or elastic fibres which run in all directions to form a network. Owing to the presence of yellow fibres, it is very flexible. It gives recoiling power structures. It is found in mammalian pinna, pharyngotympanic tube, epiglottis, some laryngeal and bronchiolar cartilages.

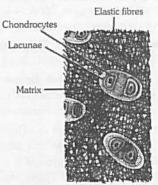

Fig: 2.3-18 Fibrocartilage Elastic

(4) Calcified cartilage: It is modified hyaline cartilage, It is hard and non elastic due to deposition of calcium salt-hydroxy appetite in matrix. It is found in pubis of old frog, supra-scapula of frog, quadrate cartilage of frog, shark vertebrae, in man ends of long bone, head of humerus and femur. Calcification may also occur as a regular growth process of bone due to age. It reduces elasticity of the cartilage and makes it more rigid.

Bone

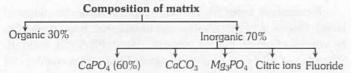

Bone is a highly calcified (mineralized), hard and rigid connective tissue. It is the major component of adult vertebrate endoskeleton. Besides its mechanical function of supporting the body architecture and internal organs as a frame work, of protecting delicate organ like brain, heart, etc. of forming to muscles to facilitate movement and locomotion, the bone is also a metabolically dynamic tissue which functions as a homeostatic reservoir of ions of calcium, magnesium, phosphorous, etc. About 97% of total calcium of body occurs in the endoskeleton.

Structure of bone

Periosteum: It is a membrane that forms an envelop around the bone. Periosteum comprises of two distinct layers. Outer layer consist of thin white fibrous connective tissue. Inner layer consist of osteoblasts. Osteoblasts are spider like bone cells, also known as bone forming cells, because they produces new bone materials.

UNIVERSAL BOOK DEPOT 1960

Matrix: Matrix is composed of protein called ossein. The matrix forms thin plates called lamellae. Lamellae are of three types. Haversian lamellae (occur around Haversian canal) concentric or circumferential lamellae (inner to periosteum and outer to endosteum) and interstitial lamellae (between Haversian system). Between the adjacent lamellae are numerous small cavities called lacunae. A lacunae gives off numerous fine branching tubules called canaliculi. Each lucuna is occupied by bone forming cells called osteocyte.

Endosteum : It is present outer to the bone marrow cavity. Endosteum is a membrane which lines the marrow cavity. It comprises of two distinct layers, one is of fibrous connective tissue and another is osteoblasts.

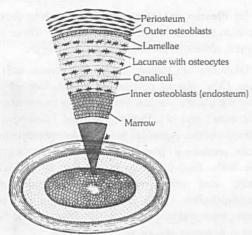

Fig: 2.3-19 T.S. of decalcified bone

Bone marrow : Bone marrow is a specialized type of soft, diffuse connective tissue called "Myeloid tissue". It takes part in production of blood cells hence known as haemopoietic tissue. It is composed of adipose tissue, areolar tissue and blood. It is of two types –

- (1) **Red bone marrow**: Red in colour due to presence of lot of blood vessels. In foetal life and at birth present in entire skeleton. After 5th year red bone marrow is replaced by yellow bone marrow, at 20-25 years red bone marrow is present in ribs, sternum, clavicles, vertebrae, scapula, pelvis, epiphysis of humerus and femur. Produces RBCs, WBC, platelets, granular leucocytes like basophils eosinophils and neutrophils.
- (2) **Yellow bone marrow**: Yellow in colour and has much fatty tissue (adipose tissue), present in shaft of long bones. Produces blood cells in emergency i.e. at the time of excessive loss of blood, yellow bone marrow may be replaced by red bone marrow in anaemia.

Haversian system: A haversian canal, its lamellae and osteocytes form a haversian system. Haversian canals are found in bone matrix of long bone, like humerus of mammals to provide extra nutrition to living part of matrix. Haversian canals contain artery and veins, osteoblasts in areolar tissue, nerves and lymph. It is also called osteon. Haversian canals are interconnected by transverse canals known as Volkmann's canals.

Types of bone cells: Four types of cells are found in bone:

- Osteoprogenitor cell: Develops into osteoblast cell due to mitotic cell division.
- (2) Osteoblast: Bone forming cells found in all bone surfaces. It is small cells which synthesize and secrete osteoid, an important part of ground substance. Process of osteoblast is called canaliculi.
- (3) **Osteocyte**: Mature, nondividing osteoblast surrounded by matrix, lying within lacunae.
- (4) Osteoclast: Bone destroying cells take part in reabsorption of bones, contain large amount of acid phosphatase enzyme.

Types of bone

On the basis of their texture: The bones are divided into two categories spongy or cancellous or tubecular bones and compact or periosteal bones.

Table: 2.3-2 Differences between Spongy bone and Compact bone

Characters	Spongy bone	Compact bone	
Arrangement of lamellae	There is no regular Haversian system so have spongy texture.	Have regular Haversian system	
Occurrence	In skull bones, ribs, centrum of vertebrae and epiphysis of long bones	In the shaft (diaphysis) of long bones	
Marrow cavity	Broad	Narrow	
Type of bone marrow	Red marrow in the spaces between lamellae	Yellow marrow in marrow cavity	
Function	Marrow forms RBCs and Granular WBCs, Platelets	Marrow stores fats	

On the basis of origin of bone: Ossification or osteogenesis is the process of bone formation. A bone is classified into four categories – Cartilaginous, Dermal, Sesamoid and Visceral bones

Table: 2.3-3 Differences between Cartilaginous, Dermal, Sesamoid and Visceral bones

Cartilaginous (Endochondrial) bone	Dermal (Intramembran ous) bone	Sesamoid bone	Visceral bone	
These are formed by ossification directly on the cartilages and formation involves deposition of body matter by osteoblasts and resorption by osteoclast.	These are formed by ossification in the dermis of the skin.	These are formed by ossification at the joints of the bones or on the tendon and ligament.	They are formed in the soft organs.	
These are elongated and hard bones Examples: Vertebrae, humerus, femur and fibula, girdles.	These are membrane-like bones. Examples : skuil bones, phalanges, clavicles.	These are small sized disc like bones. Example : patella bone (knee cap).	Examples : oscordis, ospenis, osclitoris.	

428 Animal Tissues

On the basis of treatment: These are of two types - Dried bone and Decalcified bone

Table: 2.3-4 Differences between Dried bone and Decalcified bone

Characters	Dried bone	Decalcified bone
Type of treatment	Subjected to high temperature.	Subjected to dilute solution of HCI.
Nature of matter left	With only mineral matter.	With only organic matter.
Marrow cavity	Empty.	With bone-marrow.
Fate of cells	Periosteum, endosteum, osteoblasts and osteocytes are absent being killed by high temperature.	Periosteum, endosteum, osteoblasts and osteocytes all are present.
Lacunae	Lacunae present.	Lacunae absent.

Functions of bone

- Support: Bones form the framework of the body and contribute to the shape, alignment and positioning of the body.
- (2) Protection: Bony "boxes" protect the delicate structures they enclose,
- (3) Movement : Bones with their joints constitute levers that move as muscle contract.
- (4) Mineral storage: Bones are the major reservoir for calcium, phosphorus and other minerals.
- (5) **Haematopoiesis**: Blood cell formation is carried out by myeloid tissue.

Notochord

It is found in all chordate, It is replaced by vertebral column in vertebrate. Notochord is rod like structure. Notochord is made up of chordal cells.

Vascular tissues

It is a mobile connective tissue derived from mesoderm which consists of fibre-free fluid matrix and specialised living cells that are not formed in situ, can neither divide nor secrete matrix. Vascular tissue regularly circulates in the body, takes part in transport of material and performs such activities as scavanging, healing of wounds and defence against pathogens. Vascular tissue is of two types, blood and lymph,

Blood

In chordates, and in annelids amongst the non chordates, the blood is a red and opaque fluid of salty taste and peculiar smell. It is a little heavier than water. The study of blood is called haematology. It is red coloured liquid connective tissue which originates from the mesoderm. It reaches into the various organs through the blood vessels and transports various chemical substances between different tissues. During embryonic state, the

blood is mainly formed in the liver but little blood is also formed in the spleen and ribs. In adults, the blood is formed in the red bone marrow. The blood formation is called as haemopoiesis.

Viscosity - 4.7, pH -7.4

Specific gravity - 1.04 - 1.07

Volume - 5-6 litre/70 Kg or 1/13th part of total body weight

Plasma

It constitutes about 5% of body weight. It represents matrix of blood. Plasma is slightly alkaline and transparent. It forms 55-60% by volume of blood. Plasma contains: Water (91-92%), Solid (8-9%). Plasma solid part consists of organic (7%) and inorganic (1%) substances which are as follows:

Organic constituents of plasma: Some are its own constituents, while others are those which are transported by it. All these are divisible into following categories:

(1) **Plasma proteins**: Protein constitute about 7% part of plasma and remain in it as colloid particles. These mainly include albumins, globulins, prothrombin and fibrinogen.

Globulins are mainly formed by plasma cells in lymphoid organs. Other plasma proteins are mainly formed in liver. These render the plasma viscous, and maintain its osmotic pressure (7.5 atmospheric) and pH. Prothrombin and Fibrinogen are essential for blood clotting. Albumins are mainly responsible for maintaining osmotic pressure in plasma and for osmoregulation in cells and tissue fluids. Globulins help in osmoregulation and transport of proteins and other substances, but most globulins are immunoglobulins, which act as antibodies, destroying harmful bacteria, virus and toxins in blood and tissue fluids. Some proteins, acting as enzymes, also occur in the plasma.

- (2) **Digested nutrients**: These include glucose, fats, fatty acids, phospholipids, cholesterol, nucleosides, amino acids, vitamins etc. These are supplied by the blood to all cells of body.
- (3) Excretory substances: These chiefly include ammonia collected by blood from body cells and urea, uric acid, creatine, creatinine etc., collected mainly from the liver and transported to kidneys for excretion.
- (4) Hormones: These are secreted and released in blood by endocrine glands.
- (5) **Dissolved gases :** Each 100 ml. of water of blood plasma contains about 0.29 ml of O_2 , 5 ml. of CO_2 and 0.5 ml of nitrogen dissolved in it.
- (6) Defence compounds: Certain immunoglobulins or antibodies and some other substances, such as lysozyme (a polysaccharide) and properdin (a large protein) always occur in the plasma. These serve to destroy bacteria, viruses and toxic substances that may enter into the blood from outside, or from body tissues.
- (7) Anticoagulant: Mast cells of connective tissues continuously release, in blood plasma, a conjugated polysaccharide, named heparin. The latter serves to prevent coagulation of blood while it is flowing in intact blood vessels.

UNIVERSAL BOOK DEPOT 1960

Inorganic constituents of plasma: Chloride and bicarbonate salts of sodium are the main inorganic constituents. Traces of other salts, like phosphates, bicarbonates, sulphates and iodides of calcium, magnesium and potassium are also found. All salts constitute about 1% of plasma. These remain as ions (electrolytes) and maintain the alkalinity of plasma. A balanced quantity of salt ions in the plasma is essential for proper functioning of nervous system, muscles and other tissues.

Blood corpuscles

Blood corpuscles form 40-50% of the blood and are of three types viz. Red blood corpuscles, white blood corpuscles and platelets.

(1) **Red blood corpuscles (RBCs or Erythrocytes):** These occur only in vertebrates and are the most abundant (99%) of blood corpuscles, imparting the characteristic red colour to the blood. The shape, size and structure of RBCs vary in different types of vertebrates, but their function is same in all, namely to transport respiratory gases, especially the oxygen (O₂).

RBCs of frog: Amphibian RBCs are largest amongst the vertebrates. Those of Amphibian and Proteus are largest amongst amphibians about 82 μm . These are flattened and oval, disclike, but slightly biconvex due to a large oval and centrally-placed nucleus.

RBCs of mammals: Mammals have smallest RBCs amongst the vertebrates. Those of Musk deer are smallest amongst the mammals. Whereas the RBCs of other vertebrates are oval and nucleated, those of mammals are roughly circular (except those of the family camellidae — camels, llamas, dromedaries — which are oval in shape) and non-nucleated.

RBCs of human : They are about $7.4\mu m$ in diameter and its thickness is 1 to $1.5\mu m$. It is pale yellow in colour but appear to be red in group. Surface area of all RBCs of a person totals about 1500 to 2000 times the surface area of the body itself.

Structure of RBCs: Each RBC is bounded by a dynamic, enzyme-containing plasma membrane. In human RBC, about 26.5 crore molecules of haemoglobin are packed in the intracellular framework. Water constitutes about 60% of RBC. The rest is solid. Haemoglobin forms about 34% of wet and 90% of dry weight of an RBC. Thus, 100 ml of normal human blood contains about 15 gm of haemoglobin on an average. An apparatus named haemoglobinometer is used to determine the haemoglobin contents of blood.

Structure of haemoglobin: Haemoglobin is a purple coloured iron (in the form of Fe^{+2}) containing respiratory pigment of RBCs. It consists of two parts haem (5%) and globin (95%). It is conjugated protein and made up of 4 globin chains with each attached to haem molecule by Co-ordinate bond. Globin is formed of 4 polypeptide chains 2α chain with 141 amino acids and 2β chain with 146 amino acid each. One-gram haemoglobin binds 1.34 ml oxygen. Amount of Hb is measured with the help of haemometer. A male has a greater amount of haemoglobin than a female. The amount of haemoglobin in normal man and woman is 14-16 gm/100 ml and 12–14 gm/100 ml respectively, while in children is slightly higher about 16.5 gm/100 ml of blood and foetus with 23 gm/100 ml.

Number of RBC: The number of RBC are counted by instrument haemocytometer. The total number of RBC per cubic mm of blood is called RBC count.

Table: 2.3-5

S.No.	Organism	Number of RBCs	
1.	Male	5 – 5.4 million / cubic mm of blood	
2.	Female	4.5 – 5 million / cubic mm of bloo	
3.	Infants	65 – 70 lacs/ cubic mm of blood	
4.	Embryo	85 lacs/ cubic mm of blood	
5.	Rabbit	70 lacs / cubic mm of blood	
6.	Frog	4 lacs / cubic mm of blood	

Life span of RBC: The life span of red blood corpuscles circulating in the blood stream varies in different animals. RBC have longest life span in blood.

Table: 2.3-6

S.No.	Organism	Life span of RBCs	
Mammals and Human		120 days or 4 months	
2. Rabbit		80 days	
3.	Frog	100 days	
4. New born		100 days	

Function of RBCs: The major function of erythrocytes is to receive O_2 of respiratory surfaces and then transport and readily deliver it to all cells of body. This important function is performed by haemoglobin which has a great ability to combine loosely and reversibly with O_2 and hence called "respiratory pigment". Haemoglobin, in annelids, is dissolved in the plasma because of absence of red blood corpuscles. In mollusc and some arthropods, etc., a different respiratory pigment, haemocyanin is found dissolved in the plasma. This pigment is bluish due to presence of copper in place of iron.

Haemolysis: Due to bursting of plasma membrane of RBCs. Its haemoglobin comes out. This process is called haemolysis. Some fat solvent and snake venom cause haemolysis. When RBCs are placed in hypotonic solution haemolysis take place. When human RBCs are placed in pure water or distilled water they will swell and burst. Some times in haemolysis, the RBCs lose their contents by diffusion and hence maintain their emptied forms intact. These are then called "shadows" or "ghosts" of RBCs.

Rouleaux formation: If a drop of fresh blood is placed on a slide under coverslip. RBCs adhere together by their concave surfaces like stacks or pile coins. This is called Rouleaux formation. It occurs probably due to forces of surface tension. It may also occur temporarily in blood vessels wherever circulation becomes unduly slow for some time.

ESR: It is called erythrocyte sedimentation rate. This test is measured by "Wintrobe's tube" and "Westergren's tube" method. It is the rate of sinking/settling down of RBC in the plasma to form rouleaux. Man has lower ESR as compared to women and it is lowest in new born. Normal value of ESR in male is about 5 mm and in female 10 mm in first hour. A rise in ESR indicates the presence of infective/ destructive/ inflammatory diseases.

430 Animal Tissues

- (2) White blood corpuscles (WBCs) or Leucocytes: They are nucleated, colourless and complete cells. They are bigger than RBC but their number is less. WBC shown least consistency in shape. The number of WBC is 5,000 to 10,000 per cubic mm. They are formed in red bone marrow, spleen, thymus and lymph nodes from myelocytes and the process is called as myelecoeisis. The life span of WBC is of 15 hours to 2 days. The WBC are destroyed outside the blood vessels and the process by which they come out is called as diapedesis. An increase in they number of white blood corpuscles is called leucocytosis. More than 20,000 per cubic mm. indicates some disease. A decrease below 5000/Cu.mm is called leucopenia as in typhoid fever. The leucocytes are divided into two main varieties.
- (i) **Granular leucocytes :** These cells develop in the red bone marrow from the same parent cells as the erythroblasts, i.e., myeloblast in the red bone marrow. These are granular leucocytes of roughly spherical shape, 10μ to 15μ in diameter, actively amoeboid and containing a large number of stainable granules. Their nucleus is irregular and divided into 2 to 5 interconnected lobes. Hence, these are also called polymorphonuclear leucocytes.
- (a) Neutrophils are the most abundantand, most active type of WBCs. Nucleus has 3-5lobes. They are phagocytic.
- (b) Eosinophils are phagocytic with bilobed nucleus. High eosinophil count indicates allergic conditions and parasitic infestations.
- (c) Basophils are nonphagocytic with 2-3 lobes of nucleus. They are also involved in allergic reactions.
- (ii) **Agranular leucocytes :** They have a few non-specific or no granules in the cytoplasm and the nucleus is spherical to kidney shaped. They comprise about 25–30 % of all leucocyte and have two varieties.
- (a) **Lymphocytes** Protect from pathogens and are involved in the production of antibodies.
- (b) **Monocytes** are the largest corpuscles and are phagocytic.

 Normal DLC (Differential leucocyte count) is:

Neutrophils 60-70%
Eosinophils 2-4%
Basophils 0.5-1%
Lymphocytes 20-25%
Monocytes 3-8%

(3) Blood platelets: These are protoplasmic disc that are found in mammalian blood (lower vertebrates have spindle-shaped cells named thrombocytes). Platelets arise as detached tips of protoplasmic processes extending from the cytoplasm of giant cells, megakaryocytes of red bone marrow. The shape is oval to round, often stellate. There are approximately 300,000 platelets in a cubic millimetre of blood. Platelets are non-nucleated. Life span is about 5-9 days.

Coagulation or Clotting of blood

Process of formation of blood clot is also known as blood coagulation. Normal time of blood clotting is 3 to 8 minutes. Blood clotting is checked in blood vessels by the presence of anticoagulant. When an injury is caused to a blood vessel bleeding starts which is stopped by a process called blood coagulation or clotting. This process can be described under four major stages.

I. Damaged platelets or tissue cells release thromboplastin

II. Prothrombin $\xrightarrow{Ca^{2+}}$ Thrombin

III. Fibrinogen $\xrightarrow{Ca^{2+}}$ Fibrin

IV. Fibrin + cells \longrightarrow Clot

Blood coagulation is helped by thrombocytes.

Stage I is concerned with the formation of thromboplastin released from damaged tissue or platelets. Thromboplastin helps in the formation of the enzyme thrombokinase.

Stage II involves the conversion of prothrombin into thrombin with the help of thrombokinase and calcium ions.

Stage III involves the conversion of a soluble protein fibringen in plasma to insoluble network of fibrous material called fibrin by the action of thrombin.

Stage IV is the formation of red solid mass called blood clot by trapping of blood cells particularly RBCs by fibrin network.

Table: 2.3-7 Coagulation factors

Factor	Name	Factor	Name	
1	Fibrinogen	VIII	Antihaemophilic factor	
11	Prothrombin	IX	Christmas factor or plasma thromboplastin component (PTC)	
Ш	Thromboplastin	Х	Stuart factor or Stuart-Prower factor	
IV	Calcium- ions	XI	Plasma thromboplast antecedent (PTA)	
٧	Proaccelerin (Labile factor)	XII	Hageman factor	
VI	Hypothetical factor	XIII	Fibrin stabilizing factor (FSF)	
VII	Serum prothrombin conversion accelerator (Stable factor)			

UNIVERSAL BOOK DEPOT 1960

Functions of blood: On basis of the above account, the general functions of blood can be briefly enumerated as follows:

- (1) Blood is the fluid medium which transports different materials between various parts.
- (2) The leucocytes of blood play the important role of defense by inactivating and destroying harmful toxins and invaders like bacteria, viruses, fungi and animal parasites.
- (3) Blood leucocytes phagocytes and destroy cell debris and inert foreign particles in blood and tissues. Thus, these act as "scavangers" to clean the body's internal environment.
- (4) Blood maintains the normal temperature of body. It prevents a sharp rise or fall in temperature which may be caused in any tissue due to abnormal rate of metabolism.
- (5) By coagulating at an injury, and by stimulating repairing of damaged tissues, the blood helps in rapid healing of wounds and injuries.
- (6) Blood helps in the maintenance of a proper internal environment in the body by regulating the amount of salts, acids, bases and water, etc. in the tissue fluids.

Muscular tissues

Contractility and motility (movement) are fundamental properties of protoplasm. That is why, all cells possess potential motility. Contraction for motility in the cells results essentially from the interaction of two contractile proteins, actin and myosin. These tissues are obviously responsible for movements of organs and locomotion of the body in response to stimuli. These develop from embryonic mesoderm except for those of the iris and ciliary body of eyes, which are ectodermal in origin. About 40% to 50% of our body mass is of muscles. The muscle cells are always elongated, slender and spindle-shaped, fibre-like cells, These are, therefore called muscle fibres. These possess large numbers of myofibrils formed of actin and myosin. Muscle cells lose capacity to divide, multiply and regenerate to a great extent. Study of muscle is called myology. Types of muscle are following —

Striated or striped muscles

Most muscles of body are striated. These generally bring about voluntary movements under conscious control of brain and, hence, called voluntary muscles. Most of these are inserted at both ends upon bones in different parts of the body. Hence, these are also called skeletal muscles. Movements of limbs and the body solely depend upon these muscles. Hence these are also called somatic muscles. These are also called phasic type of muscles, because contraction in these is rapid, but brief and fatigue occurs quickly.

Fine structure of striated muscle fibres: Striated muscle fibres shows transverse striation in the form of regular alternate dark A (anisotropic) and light I (isotropic) bands. The 'A' band contains about 120Å thick and 1.8 μ long "myosin filaments". The I band contains about 60Å thick and 1.0 μ long "actin filament" which are twice as many as myosin filaments. Each I band is divided into two equal halves by a thin, fibrous and transverse zigzag partition, called 'Z' band ('Z' disc) or Krause's membrane. Each segment of a fibril between two adjacent 'Z' bands is called a sarcomere. It is 2.3 µ long in uncontracted mammalian striated fibres. A slender transverse line, the 'M' or Hansen's line is visible in middle of each 'A' band. The major, middle region of 'A' band is comparatively lighter, but its terminal parts appear darker. The middle lighter region is called 'H' zone. Due to the geomatric bonding pattern, the end of each myosin filament is, thus, encircled by the ends of six actin filaments (hexagon), while the end of each actin filaments is encircled by the ends of three myosin filaments (trigon).

Ultrastructure of myofilaments: At the molecular level, each myosin filament is composed of about 500 thread-like myosin molecules. Three different kinds of proteins participate in the composition of actin filaments. The major part of an actin filament is a coiled double helical strand whose each arm is a linear polymer of small and globular molecules (monomers) actin protein. Another coiled double helical, but thiner, strand runs along the whole length of actin strand. Each arm of this strand is a polymer of fibre-like molecules of tropomyosin protein. The third protein is troponin.

Working of striated muscles: H.E. Huxley and A.F. Huxley in 1954 proposed a theory to explain the process of muscular contraction. This theory is known as 'sliding filament theory'. It was observed that when a fibril contracts, its 'A' bands remain intact, while the 'I' bands progressively shorten and eventually disappear when the fibril has shortened to about 65% of its resting length. At this stage. 'H' zones also disappear because the actin filaments of both sides in each sarcomere reach, and may even overlap each other at the "M" line, and the 'Z' lines now touch the ends of myosin filaments. It was further observed that if a fibre is mechanically streched, the zones of overlap between thick and thin filaments are shorter than in resting condition, resulting in wider 'H' zones. These observations led Huxley to propose that shortening of the fibrils in contraction is brought about by sliding movement of actin filaments over myosin filaments towards "M" line by means of rapidly forming and breaking cross bridges or rachets at the spurs of myosin filaments. Thus, the sarcomere were recognised as the 'ultimate units of contraction'.

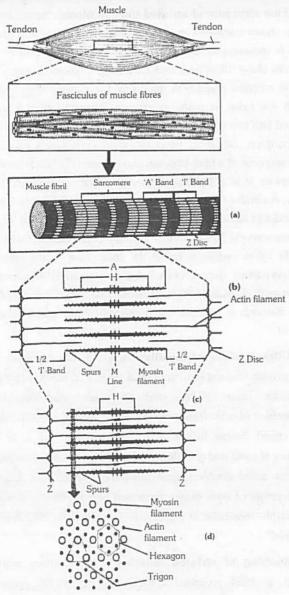

Fig: 2.3-20 Ultrastructure of a relaxed striated myofibril
(a) a sarcomere (b) & (c) a contracted sarcomere: (d) T.S.
through terminal part of a A band

Smooth muscles

These are called smooth, plain nonstriated involuntary or unstriped muscles due to absence of striations. These occur in the walls of hollow internal organs (alimentary canal, gall bladder, bile ducts, respiratory tracts, uterus, urinogenital ducts, urinary bladder, blood vessels, etc.), in capsules of lymph glands, spleen etc., in iris and ciliary body of eyes, skin dermis, penis and other accessory genitalia, etc. There is no connection of these muscles with bones. Smooth muscles of skin dermis, called arrector pilli muscles, are associated with hair roots, and are responsible for flesh (erection of hairs). Those of penis form a muscular network which helps in its erection and limping.

Structure : Smooth muscle fibre is unbranched goose-spindle shaped, uninucleated and has no sarcolemma. Contraction is slow, involuntary under the control of ANS. Functionally smooth muscles are of two types –

- (1) **Single-unit smooth muscle**: Single unit smooth muscle fibres are composed of muscle fibres closely joined together, contract as a single unit. e.g., urinary bladder, gastrointestinal tract, small arteries and small veins.
- (2) **Multi-unit smooth muscles:** Are composed of more independent muscle fibres, contract as separate units e.g. hair root muscle, muscles on the wall of large blood vessels, ciliary muscles, muscles of iris and bronchi.

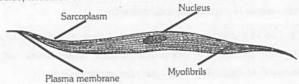

Fig: 2.3-21 Smooth muscle

Cardiac muscles

Heart wall (also the wall of large veins just where these enter into the heart) is made up of cardiac muscles and, hence, called myocardium. Structurally, these muscles resemble striated muscles but, functioning independently of the conscious control of brain, these are involuntary like the smooth muscles. Cardiac muscle cells of fibres are comparatively shorter and thicker, cylindrical, mostly uninucleate with a central nucleus, somewhat branched and covered by a sarcolemma.

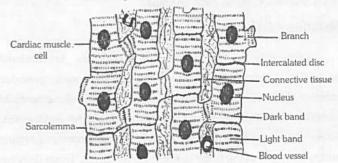

Fig: 2.3-22 Cardiac muscle fibres

Characteristics of a muscle

Antagonistic muscles: The striated muscles occur in antagonistic pairs; one pulls a bone in one direction, while the other pulls it back in reverse direction to its normal position. For example, the biceps muscle, extending from shoulder to radius, bends or flexes the arm at the elbow, whereas the triceps extending from ulna to the shoulder, straightens the arm. Thus, biceps is a flexor and triceps an extensor for bending the arm.

Single twitch: Twitch is a rapid, jerky response to a stimulus. When a muscle receives a single excitation impulse, it respond by a sudden partial contraction (twitch) lasting for about 0.5 second in man. Each twitch is followed by a refractory period during which the muscle does not respond to next stimulus. The refractory period is, however, so short (0.002 second) that the muscle can respond to the second stimulus while still in contraction phase in response to the first stimulus.

Tetanus: Generally, whole muscles contract, not in a single twitch, but in sustained contractions evoked by a series of nerve impulses reaching them in rapid succession. Such a sustained contraction is called tetanus. Described above should not be confused with the disease of "tetanus" (lock jaw) caused by tetanus

UNIVERSAL BOOK DEPOT 1960

bacillus. This disease is characterised by abnormal muscular contractions. Nor it should be confused with "tetany" which is muscular spasm occurring due to deficiency of parathyroid hormone.

Muscle tone or "Tonus": Even at rest the striated muscles normally remain in a state of mild sustained partial contraction to maintain the body posture. This is called muscle tone. It is a mild state of tetanus.

Paralysis: When supply of motor impulses to a muscle is completely cut off due to destruction, either of the control centres in brain, or of the concerned motor nerves, or due to blocking of myoneural junctions by the use of certain drugs, the muscle function is completely impaired. This is called paralysis of the muscle.

Muscle fatigue: A muscle that has contracted many times at short intervals, exhausts its store of ATP and glycogen and accumulates lactic acid. Hence its contractility gradually decreases and finally stops.

Oxygen debt: During active work or exercise, the rate of oxygen supply by the lungs falls short of the requirement of the muscles. Hence, lactic acid accumulates in the muscles and the breathing gradually becomes hard to enhance O_2 intake by the lungs. This is called oxygen debt.

Involuntary action of skeletal muscles: Muscles are capable of utilizing, in their mechanical work, only about 20% to 40% of energy liberated from glucose. The unutilized energy is lost as "heat" dissipated into the environment. This heat helps in maintenance of body temperature. "Shivering with cold" in winter is caused by a quick involuntary reaction of striated muscles.

Rigor mortis : Rigidity that develops in the muscles after death is known as rigor mortis. It is due to permanent irreversible contraction, establishment of permanent link between actin and myosin and also fall in the concentration of ATP molecules.

Cori's cycle: Lactic acid is transported by blood to liver and there it is converted to glycogen through Cori's cycle.

Contraction period : Time taken in sliding of filament is called contraction time. (10 to 100 milli second).

Relaxation time: It is time taken in relaxation of fibre i.e. active transport of calcium from sarcoplasm to cisternae. (10 to 100 milli second)

Refractory period : It is time in a muscle or nerve fibre when they are non responding to second stimulus. Infact in this period there is temporary loss of excitability. Refractory period for skeletal and cardiac muscle is 5 and 300 milli second respectively.

Hypertrophy and Atrophy of muscles: Muscles which are put to excessive work become thick and strong. This is called their hypertrophy. Conversely, if certain muscles are not used for a long period, those become thin and weak. This is called their atrophy (disuse atrophy). Cardiac muscle have a poor regenerative power.

Nervous tissue

A most complex tissue in the body, composed of densely packed interconnected nerve cells called neurons (as many as 10^{10} in the human brain). It specialized in communication between the various parts of the body and in integration of their activities.

Nervous tissue is ectodermal (from neural plate) in origin. It forms the nervous system of the body which controls and coordinates the body functions. There is no intercellular matrix between neurons. These have permanently lost the power of division as have no centriole and have minimum power of regeneration. So these cannot be cultured in vitro. Irritability is the main function of nervous tissue.

Composition of nervous tissue : Nervous tissue is formed of four types of cells :

- (1) Neurons (nerve cells)
- (2) Neuroglia
- (3) Ependymal cells
- (4) Neuro-secretory cells

Neurons

A neuron is a nerve cell with all its branches. Neuron is formed from neuroblast. It is the structural and functional unit of nervous system. It is the longest cell of the body.

- (1) Cyton: It is also called perikaryon or soma or cell body. Its granular cytoplasm is called neuroplasm which has following structures:
- (i) A large, spherical, centrally placed nucleus with a single nucleolus.
- (ii) Numerous fine threads called neurofibrils for the conduction of nerve impulses.
- (iii) A number of small, basophilic granules called Nissl's granules formed of rough endoplasmic reticulum with ribosomes and are sites of protein synthesis.
- (iv) Neuroplasm has large number of mitochondria to provide high energy for impulse conduction.
- (v) Neuroplasm may have melanophores with melanin pigment and lipochromes with orange or yellow pigment.
 - (vi) A mature neuron has no centriole, so it cannot divide.
- (vii) A "Barr body" is often seen abutting against the inner surface of nuclear membrane of cytons in females. This has been proved to be a transformed 'X' chromosome.
- (viii) Certain neurons having flask-shaped cytons and called purkinje cells, occur in the cerebellum of the brain.
- (2) **Neuron processes:** The processes of neurons, called neurites, extend varying distances from the cyton and are of two types dendrites or dendrons and an axon or axis cylinder (neuraxon).
- (i) **Dendron :** These are several short, tapering much branched processes. The dendrites contain neurofibrils, neurotubules, Nissl's granules and mitochondria. They conduct nerve impulse towards the cell body.
- (ii) Axon: This is a single very long, cylindrical process of uniform diameter. It arises from a conical projection, the axon hillock, of the cyton. The axon contains neurofibrils and neurotubules but lacks Nissl's granules. Axon is usually branched only terminally into slender branches called telodendria. The latter have knobbed ends called endbulbs or axon terminals or buttons or synaptic knobs or end plates. The synaptic knobs contain mitochondria and secretory vesicles.

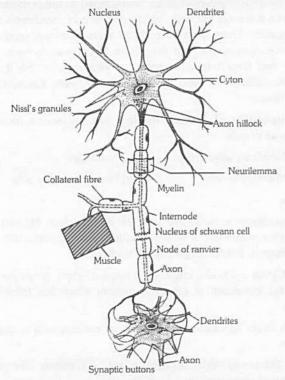

Fig : 2.3-23 An Enlarged Neuron and its synapses with another Neuron

Types of neurons : Neurons are divided into different categories on different basis.

(1) On the basis of functions: Neurons are divided into three categories:

Sensory (afferent) neurons: These are found in sense organs. Their dendrons receive the nerve impulse from the nerve process of the receptor cell while their axon forms the synapse with dendron of the next neuron. These may be naked or encapsulated e.g. olfactoreceptors and gustatoreceptors.

Internuncial neurons: These are located in the dorsal horn of the spinal cord. These are called association neurons (when their axon synapses with the dendron of motor neuron of same side) or commissural neuron (when their axon synapses with the dendron of motor neuron of opposite side).

Motor (efferent) neurons: These are always present in the ventral horn of the spinal cord. Their axon ends into the muscle fibres or glands cells. These conduct the nerve impulses to the effector organs which respond to the stimuli.

(2) On the basis of number of nerve processes : Neurons are of three types –

Unipolar neurons: In these neurons, only one nerve process arises from the cyton which acts as axon but there is no dendron. These are found only in early embryos. The unipolar neuron of the adult gives rise to a single nerve process, which immediately divides into a dendron and an axon. Such unipolar neurons are called pseudo-unipolar neurons. These are found in the dorsal root ganglia of spinal nerves and in the roots of V, IX and X cranial nerves.

Bipolar neurons: In these neurons, the cyton gives rise to two nerve processes out of which one acts as an axon while other acts as a dendron. These are found in the olfactory epithelium of nasal chamber and retina of eye. These may be isopolar or heteropolar (dendrons being irregularly branched). Ganglia of VIII cranial nerve.

Multipolar neurons: In these neurons, the cyton gives rise to several nerve processes out of which one acts as an axon while remaining nerve processes act as dendrons. These are found in the central nervous system and the ganglia of autonomic nervous system of adult.

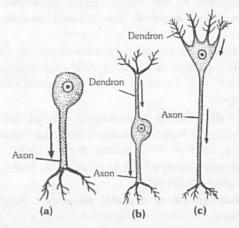

Fig : 2.3-24 Types of Neurons (a) Unipolar; (b) Bipolar; (c) Multipolar

Neuroglia or Glia cells

Neuroglia consists of the supporting and packing cells found in the brain, spinal chord and ganglia. These are non nervous cells. These are ten times more numerous than neurons. In some parts of body the neuroglial cells are called by certain other name such as muller cells in retina, pituicytes in posterior pituitary gland and satellite cells in ganglia.

Types: The neuroglia cells are of three types -

- (1) Astrocytes: These are large sized and star-shaped cells with numerous processes which form blood brain barrier therefore only located in brain.
- (2) **Oligodendrocytes**: These have a few branched processes which resemble the dendrons of the neurons. Forms myelin sheath around CNS Axon, example schwann cells.
- (3) **Microglial cells**: These are small sized and spindle-shaped. The microglia cells act as the defensive phagocytes in central nervous system. They arise from the monocytes.

Functions

- (1) These are capable of division and help in wear and tear of the central nervous system.
- (2) These insulate the adjoining neurons and prevent the lateral transmission of impulses.
 - (3) These provide nutrition to the neurons.
 - (4) These act as phagocytes and eat up the microbes.
 - (5) These help in memory processes.

(6) They acts as Blood brain barrier (BBB) i.e. they inhibit contact between neuron and blood, along with endothelium of capillary. The exchange of material between blood and neuron is always through these neuroglial cells i.e., they are mediator.

Ependymal cells

These are cuboidal and ciliated epithelial cells which lines the cavities of brain (ventricles) and spinal cord (central canal). These form an epithelium called ependyma. Ependymal cell for circulation of CSF.

Neurosecretory cells

These are special type of neurons of the hypothalamus of brain. These are endocrine in function and secrete neurohormones which are carried by the blood of hypophyseal portal system to anterior lobe of pituitary gland and stimulate the secretion of their trophic hormones e.g., TSH, STH, FSH, LH, ACTH, etc.

Nerve fibres

Axon or dendron of a nerve cell covered with one or two sheath is termed as nerve fibre. The nerve fibres are of two types – medullated or myelinated and non medullated or non myelinated regarding their structure.

- (1) **Medullated nerve fibres**: A medullated nerve fibre typically consists of a central core, the axis cylinder, or neuraxis, surrounded by two sheaths: inner thick medullary sheath and outer thin neurilemma.
- (i) Axis cylinder: The axis cylinder is simply the axon or dendron of a nerve cell. It contains longitudinal neurofibrils and mitochondria in its neuroplasm, called axoplasm, limited by cell membrane termed axolemma. It is the axolemma that conducts the nerve impulses.
- (ii) **Medullary sheath**: The medullary sheath is composed of a shinning, white, fatty substance called myelin. This sheath perhaps serves as an insulating layer, preventing loss of energy of the nerve impulse during its passage along the fibre. It causes saltatory conduction of impulses. The medullary sheath is continous around the fibres in the central nervous system, but in the fibres of the peripheral nerves it is absent at certain points known as the Node of Ranvier. The part of a nerve fibre between two successive nodes is termed the internode.
- (iii) Neurilemma: The neurilemma consists of tubular sheath cells (Schwann's cells) placed end to end. The neurilemma is continuous over the Nodes of Ranvier. The function of the Schwann's cells is to produce the myelin sheath around the neuraxis. The medullated nerve fibres within the brain and spinal cord lack neurilemma. Instead, they have an incomplete covering of neuroglia cells, which probably produce the myelin sheath. Neurilemma present around the peripheral nerve fibres enables them to regenerate after injury. Nerve fibres in the brain and spinal cord do not regenrate after injury due to lack of neurilemma. The medullated nerve fibres occur in the white matter of the brain and spinal cord and in the cranial and spinal nerves.
- (2) Non medullated nerve fibres: A non medullated nerve fibre consists of an axis cylinder enclosed by neurilemma and connective tissue. These fibres appears grey in colour in the fresh state. The non-medullated nerve fibres occur in the autonomic nerves.

Table: 2.3-9 Difference between medullated and nonmedullated nerve fibre

s.N	Characters	Medullated nerve fibres	Non-medullated nerve fibres
1.	Occurrence	Found in white matter of brain, spinal cord, cranial and spinal nerves	Found in grey matter of brain and spinal cord, and in autonomic nervous systems.
2.	Sheaths	Neuraxis covered by inner medullary sheath and outer neurilemma	Neuraxis covered by only neurilemma. Medullary sheath is absent
3.	Nodes of Ranvier and internodes	Present	Absent
4.	Diameter	More	Less
5.	Colour	White	Grey
6.	Speed of con duction of nerve impulses.	Faster due to saltatory conduction of nerve impulses	Slower
7.	Collateral branches	Present	Absent

Nerves

The nerves are thread like structures extending between the central nervous system and the receptor or effector organs of the body. These conduct the nerve impulses to and from the central nervous system.

Each nerve is formed of several bundles of nerve fibres, called fasciculi. Each nerve fibre of the bundle is covered by a thin sheath of connective tissue called endoneurium, while each fasciculus is enclosed by another sheath of white fibrous connective tissue called perineurium. All the fasciculi are held together by the connective tissue and are enclosed by a thick coat of white fibrous connective tissue called epineurium. On average, a nerve contains about twice as many unmyelinated fibres as myelinated fibres.

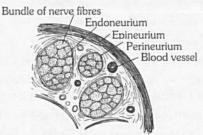

Fig: 2.3-25 T.S. of Nerve

Types of nerves : The nerves are of three types according to the nature of the nerve fibres they are composed of –

- (1) **Sensory or afferent nerves :** The nerves with sensory fibres are called sensory nerves. It brings the impulse towards the central nervous system. Example Olfactory, optic and auditory nerves (I, II, VIII).
- (2) Motor or efferent nerves: The nerves having efferent fibres are termed motor nerves. It carries the impulses away from central nervous system. Example Oculomotor, Pathetic and abducens nerves (III, IV, VI).

(3) Mixed nerves: Some nerves have both afferent and efferent fibres. These are known as mixed nerves. Example – Trigeminal, facial, glossopharyngeal and vagus nerves (V, VII, IX, X).

Tips & Tricks

- The brown adipose tissue in human is restricted till third month of post natal life.
- Plasma cells are also called as "Cart wheel cells".
- The term "blubber" refers to subcutaneous deposition of fat in whales.
- ∠ Ligamentum flava connects adjacent vertebrae and the ligaments between the phallanges, fingers and toes.
- ∠ Ligamentum nuchae Found in the neck of quadrapeds to bear the weight of head when grazing.
- Teeth are made up of dentine (bone) and its crown is covered by enamel, which is the hardest substance of the body.
- Astronauts pass out calcium in their urine due to faster breaking down of bones, due to absence of gravitational pull.
- Strongest cartilage is fibrocartilage due to collagen fibres.
- ✓ Diploic bone Bone with compact surfaces and cancellous middle e.g., skull bone, vertebrae.
- Beside calcium phosphate (major constituents) the bones contain potassium, magnesium hydroxide.
- Study of cartilage is called chondrology.
- Long bones possess pits of Howship.
- ✓ Normal blood glucose level is 90 120 mg/100 ml.
- Strontium 90 is the chemical which causes damage to WBC, bone marrow, spleen, lymph nodes and lungs.
- Bone marrow is absent in birds due to Pneumatic bones.
- Granulocyte are formed inside Red bone marrow.
- Haemocytometer is used for red cell counting.
- Phagocytosis was first of all seen by Metchnikoff.
- Blood doping or blood boosting is the transfusion of one's own blood or frozen RBC to increase haemoglobin content to carry more oxygen.
- ✓ Polycythemia Abnormal rise in number of RBC.
- ✓ When muscles contract they have squeezing effect on veins running through them. It is termed as muscle pump.

- Tongue muscles and muscles of upper part of oesophagus are striated muscles, but without any bone.
- Cholesterol concentration is highest in cardiac muscle.
- Phospholipids concentration is maximum in cardiac muscle.
- The muscles change gradually from voluntary to involunatry in the upper part of oesophagus.
- \angle Lohman Reaction : ADP + Phospho Creatine \rightarrow ATP + creatine
- Chronaxie is defined as the shortest duration of stimulus required to excite a tissue by a current strength.
- Painful contractions of muscles is called muscle cramp.
- ★ Total number of muscles in human body is 639
- Largest muscle is gluteus maximus (Buttock muscle).
- ∠ Longest muscle is sartorius.
- Papillary muscles are associated with heart.
- Pectoralis major is flight muscle in bird
- Latissimus dorsi is the muscle of shoulder.
- Ciliary muscle is associated with eye-change focal length of lens.
- Maximum muscles in back region i.e. 180
- Minimum muscles in Neck region i.e. 32
- Masseter Lower jaw, the strongest muscle in the body.
- Rectus abdominis Longest visceral muscle found in abdomen.
- Myology Study of muscles.
- Myogram Recording of muscular contraction.
- Muscular dystrophy A hereditary disease of muscle.
- Poliomyelitis Viral disease that weakens the muscles.
- ★ The value of resting membrane potential is 60 to 90 mV.
- S GABA is slow neurotransmitter substance.
- Synapse is a junction between dendrites and axons ends.
- Neuroglial cells differs from neurons in having no Nissls granules.
- Nerve fibres are different from the muscles fibres due to the presence of dendrites.
- Branched ends of nerve cells are called telodendria which establish the functional contact with other nerve cell this connection is called synapse.
- Most of the neurons of our body are multipolar.
- Nissl's bodies are absent in axon and axon hillock.

Ordinary Thinking

Objective Questions

Epithelial tissue

Name the type of tissue that form gland

[NCERT; Odisha JEE 2008; MP PMT 2010]

(a) Epithelial

(b) Muscular

(c) Squamous

(d) Cuboidal

2. In thyroid follicle which type of epithelial tissue is present

[Odisha JEE 2008]

(a) Squamous

(b) Cuboidal

(c) Transitional

(d) Columnar

Stereocilia occur in

[AMU (Med.) 2010]

(a) Pseudostratified columnar epithelium of trachea

(b) Columnar epithelium of stomach

(c) Stratified columnar epithelium of pharynx

(d) Pseudostratified columnar epithelium of epididymis

4. Skin is a [CPMT 2010]

(a) Cuboidal epithelium

(b) Columnar epithelium

Pseudostratified epithelium

(d) Stratified epithelium

5. The cell junctions called tight, adhering and gap junctions are found in [NCERT: CBSE PMT 2009]

(a) Muscular tissue

(b) Connective tissue

(c) Epithelial tissue

(d) Neural tissue

6. Note the following

(A) It forms the lining of the cavities of alveoli of the lungs

(B) It forms the lining of wet surfaces like buccal cavity and oesophagus

(C) It occurs in the ducts of sweat glands

(D) It forms the lining of salivary glands and sweat glands

(E) It is a loose connective tissue

Which of the above are associated with simple epithelial tissue [EAMCET 2009]

(a) A and D

(b) B and C

(c) C and A

(d) D and E

7. Mammary glands are modified

[BHU 2008]

(a) Cutaneous glands

(b) Sebaceous glands

(c) Sweat glands

(d) Scent glands

In which one of the following preparations are you likely to come across cell junctions most frequently [CBSE PMT 2007]

(a) Ciliated epithelium

(b) Thromobocytes

(c) Tendon

(d) Hyaline cartilage

The function of villi in the intestine is

INCERT: AIEEE Pharmacy 2003; CBSE PMT 2005;

Odisha JEE 2010]

(a) Absorption of food

(b) Increase in the absorptive surface of food

(c) Control of intestinal movement

(d) Hinderance in the movement of food

Reproductive cells (germinal epithelium) are made up of which of the following epithelial tissue

(a) Cuboidal

(b) Columnar

(c) Squamous

(d) Sensory

Schneiderian membrane is found in

(a) Nasal passage

(b) Trachea

(c) Bowman's capsule

(d) Loop of Henle

The ciliated epithelium in our body may be found in

[CBSE PMT 1993; MP PMT 1997; RPMT 2005, 06]

(a) Ureter

(b) Trachea

(c) Stomach

(d) Uterine tube

Cells of squamous epithelium are

[MP PMT 1994]

(a) Tall with elongated nuclei

(b) Cube like

(c) Flat and tile like

(d) Columnar or cuboidal in shape

The cells lining the blood vessels belong to the category of

[NCERT; J & K CET 2008; CBSE PMT (Pre.) 2010:

CBSE PMT (Mains) 20111

(a) Columnar epithelium

(b) Connective tissue

(c) Smooth muscle tissue

(d) Squamous epithelium

15. Urethra, vagina and oesophagus have a common inner lining [CMC Vellore 1993; MP PMT 2003; Odisha JEE 2005]

(a) Squamous epithelium

(b) Ciliated epithelium

(c) Columnar epithelium

(d) Stratified squamous epithelium

16. Epithelial tissue performs the following functions

[NCERT; KCET 1994; MP PMT 1995]

(a) Protection, secretion, absorption, respiration

(b) Protection, secretion, sensation, absorption

(c) Protection, secretion, absorption, digestion

(d) None of these

17. Simple epithelium is [DPMT 1993]

(a) One cell thick

(b) Two cells thick (c) Two or three cells thick (d) All are correct

The cellular layers in epidermis of skin consists of 18.

(a) Glandular cells

(b) Columnar cells

(c) A squamous stratified cornified epithelium

(d) A complex stratified epithelium

Ciliated epithelium in vertebrates is present in 19.

(a) Kidney and stomach

(b) Buccal cavity and oviduct of frog

(c) Stomach and urinary tubules

(d) Lymph vessels

The secretion of tears, milk, sweat and oil are functions of 20. which of the following tissues [J & K CET 2012]

(a) Epithelial

(b) Nervous

(c) Loose connective

(d) Lymphoid

21. Desmosomes are the feature of [CBSE PMT 1992: AFMC 1993, 99; KCET 2000; BHU 2001]

> (a) Epithelial tissue (c) Muscular tissue

(b) Nervous tissue

Nature of mammary gland is

(d) None of these [MP PMT 2002]

(a) Apocrine (c) Holocrine

(b) Merocrine (d) None of these

23 An example of merocrine gland is

[MP PMT 2001]

(a) Sebaceous gland

(b) Pineal gland

(c) Salivary gland

(d) Mammary gland

- Simple coiled tubular glands are found in
- [CPMT 1993]

- (a) Dermis of skin
- (b) Kidney
- (c) Liver
- (d) Spleen
- See the following figures 25.

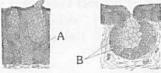

Figure A and B indicate glands while Figure C indicates specific type of tissues. Identify A, B and C

1	A	В	C
(a)	Unicellular gland	Goblet gland	Pseudostratified epithelium
(b)	Multicellular gland	Unicellular gland	Pseudostratified epithelium
(c)	Unicellular gland	Multicellular gland	Pseudostratified epithelium
(d)	Unicellular gland	Multicellular gland	Compound epithelium

- In animals, gametes are derived from 26.
- [Kerala PMT 2004]
 - (a) Epithelial tissue
- (b) Nervous tissue
- (c) Occur singly
- (d) None of the above
- Tissue which has power of division and regeneration 27. throughout life
 - (a) Epithelial tissue
- (b) Muscular tissue
- (c) Connective tissue
- (d) Nervous tissue
- The ciliated columnar epithelial cells in humans are known 28. to occur in [NCERT; MP PMT 2000; AIEEE Pharmacy 2004; Kerala PMT 2007; CBSE PMT (Pre.) 2011; WB JEE 2011]
 - (a) Fallopian tubes and urethra
 - (b) Eustachian tube and stomach lining
 - (c) Bronchioles and Fallopian tubes
 - (d) Bile duct and oesophagus
- Stratified squamous epithelium is found in
 - (a) Trachea
- (b) Epidermis
- (c) Mouth cavity (buccal)
- (d) Lining of blood vessels
- Compound squamous epithelium is found in [BHU 1995] 30.
 - (a) Stomach
- (b) Intestine
- (c) Trachea
- (d) Pharunx
- Find out the wrongly matched pair 31.
- [Kerala PMT 2007]

[AFMC 1995]

- (a) Squamous epithelium
- Skin of frog
- (b) Columnar epithelium
- Peritoneum of body cavity
- (c) Ciliated epithelium
- Bronchioles
- (d) Stratified cuboidal
 - epithelium
- Oesophagus
- (e) Glandular epithelium
- Salivary gland
- The epithelium in the bronchioles is [MP PMT 1996, 2002]
 - (a) Pseudostratified and columnar
 - (b) Squamous and sensory
 - (c) Pseudostratified and sensory
 - Cuboidal and columnar

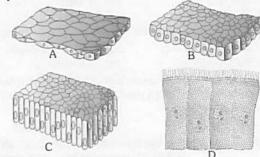

Which type of epithelium is found in oesophagus, buccal 33. cavity, cornea, vagina and cervix

[KCET 2007; Odisha JEE 2011]

- (a) Transitional epithelium
- (b) Columnar epithelum
- (c) Non-keratinized stratified epithelium
- (d) Keratinized stratified epithelium
- Match the following simple epithelial tissues in column I with 34. their occurrence in column II and choose the correct combination from the options given

Column II Column I

- A. Squamous
- 1. Intestinal glands
- Cuboidal
- 2. Trachea 3. Ovary
- C. Columnar
- 4. Blood vessels
- D. Ciliated
- Pseudo stratified
- 5. Bronchioles
- [DPMT 2004; Kerala PMT 2006]
- (a) A-1, B-2, C-4, D-3, E-5
- (b) A-5, B-4, C-2, D-1, E-3
- (c) A-4, B-5, C-1, D-2, E-3
- (d) A-4, B-3, C-1, D-2, E-5
- (e) A-4, B-3, C-1, D-5, E-2
- Which of the following is the characteristic of epithelial 35. [KCET 2001] tissues
 - (a) They are highly vascularised
 - (b) They never produce glands
 - (c) They have large intercellular spaces
 - (d) They have a rapid rate of cell division
- The type of epithelium found in conjunctiva of eye is 36.
 - [MP PMT 2001]
 - (a) Stratified cuboidal
- (b) Stratified columnar
- (c) Stratified squamous
- (d) Transitional epithelium
- Outer layer of skin is made up of keratinised epithelium, this 37. [RPMT 2001]
 - (a) It is exposed thus subjected to wear and tear
 - (b) It covers the whole body
 - (c) It is thick
 - (d) It prevents the entry of pathogens
- See the following figure and identify the following simple epithelial tissues

	A	В	С	D
(a)	Squamous	Cuboidal	Columnar	Pseudostratified columnar (ciliated)
(b)	Pseudostratified squamous	Cuboidal	Columnar	Ciliated columnar
(c)	Squamous	Cuboidal	Columnar	Ciliated columnar
(d)	Cuboidal	Squamous	Columnar	Ciliated columnar

39. The intestine and stomach in mammals are lined by

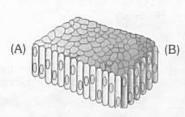

[J & K CET 2002]

- (a) Cuboidal epithelium
- (b) Columnar epithelium
- (c) Squamous epithelium
- (d) Stratified epithelium
- 40. Pseudostratified columnar epithelium is found in

[MP PMT 2003]

- (a) Wall of cloaca
- (b) Male urethra
- (c) Oviduct
- (d) Oesophagus
- Epithelial tissues arise from 41.
- [MP PMT 1996, 2002]
- (a) Ectoderm (c) Mesoderm
- (b) Endoderm (d) All of the above
- 42. The four sketches (A, B, C and D) given below, represent four different types of animal tissues. Which one of these is correctly identified in the options given, along with its correct location and function

[NCERT; CBSE PMT (Mains) 2012]

		Tissue	Location	Function
(a)	(B)	Glandular epithelium	Intestine	Secretion
(b)	(C)	Collagen fibres	Cartilage	Attach skeletal muscles to bones
(c)	(D)	Smooth muscle tissue	Heart	Heart contraction
(d)	(A)	Columnar epithelium	Nephron	Secretion and absorption

Connective tissue

1. Glisson's capsule is a delicate connective tissue capsule covering the [KCET 1994; MP PMT 2002]

Glisson's capsule is found in

[MP PMT 1998, 2009; CPMT 2001; Kerala PMT 2008]

- (a) Spleen
- (b) Liver
- (c) Kidney
- (d) Gall bladder
- 2 The type of connective tissue that is associated with the umbilical cord is [EAMCET 2009]
 - (a) Areolar connective tissue
 - (b) Jelly-like connective tissue
 - (c) Adipose connective tissue
 - (d) Reticular connective tissue

- Which of the following cells of connective tissue secrete antibodies [CPMT 2005]
 - (a) Mast cells
- (b) Reticular cells
- (c) Adipose cells
- (d) Plasma cells
- 4. The mast cells secrete the following substance [DPMT 1993: CBSE 1998, 2006; CPMT 1998, 2000, 03, 09: AFMC 2002; BHU 2003, 06; MP PMT 2007]
 - (a) Heparin
- (b) Histamine
- (c) Serotonin
- (d) All of the above
- Originating in bone marrow, circulating in blood for 1-2 days, migrating to connective tissue and forming macrophages is a characteristic of [AMU (Med.) 2010]
 - (a) Eosinophils
- (b) Basophils
- (c) Monocytes
- (d) Lymphocytes
- In allergic reaction which is secreted

[Bihar CECE 2006; AIIMS 2009] Or

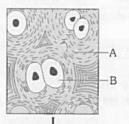

The symptoms of an allergic reaction develop in response to [WB JEE 2016]

- (a) Histamine
- (b) Neutrophil
- (c) Basophil
- (d) Acidophil
- The areolar tissue connects
- [CBSE PMT 2006]

- (a) Two bones
- (b) Muscle and the bone
- (c) Muscle and the fat tissue
- (d) Muscles and their compound
- Ligaments and tendons are **INCERT: MP PMT 1996:** AFMC 1999, 2010; CPMT 2001, 03; BHU 20061
 - (a) Connective tissue
- (b) Muscular tissue
- (c) Fibrous connective tissue (d) Skeletal tissue
- 9. Collagen fibres of connective tissue are

[NCERT; CPMT 1999; J & K CET 2012]

- (a) White
- (b) Yellow
- (c) Colourless
- (d) Red
- [DPMT 1993; MHCET 2004]
- Camel's hump is made up of (a) Skeletal tissue
- (b) Muscular tissue
- (c) Cartilage
- (d) Adipose tissue
- Study the figure I and II carefully and identify the structures A, B and C respectively which are related with specialized connective tissues [NCERT]

	Fig. I	Fig. II	A	В	С
(a)	Bone	Cartilage	Collagen fibres	Osteoblast	Lamella
(b)	Cartilage	Bone	Microtubule	Chondroclast	Lamella
(c)	Cartilage	Bone	Collagen	Chondroclast	Lamella
(d)	Cartilage	Bone	Collagen	Chondrocyte	Lamella

- 12. Whale is a warm-blooded animal which lives in cold sea. Which organ of its body makes it hot
 - (a) Blubber
- (b) Pelage
- (c) Muscles
- (d) Blood vessels
- 13. Below the skin, the fat is in the form of

Or

Which of the following helps in maintaining body hot

- (a) Lipoproteins
- (b) Adipose tissue
- (c) Mucous layer
- (d) Lymphoid tissue
- 14. Which statement is incorrect

[AMU (Med.) 2010]

- (a) Mast cells and basophils secrete histamine and heparin
- (b) Mast cells are long lived, basophils are short lived
- (c) Mast cells are smaller than basophils with a bilobed nucleus
- (d) Mast cells are relatively sessile, basophils are mobile
- 15. The types of fibres found in connective tissues are
 - (a) Collagan fibres
- (b) Elastic fibres
- (c) Reticular fibres
- (d) All of the above
- 16. The intercellular substance found in connective tissue is
 - (a) Fatty in nature
 - (b) Muco-polysaccharide
 - (c) Mainly protein in nature
 - (d) All are correct
- 17. Given below is the diagrammatic sketch of a certain type of connective tissue. Identify the parts labelled A, B, C and D, and select the right option about them

[NCERT; CBSE PMT (Mains) 2012]

	Part-A	Part-B	Part-C	Part-D
(a)	Macro-phage	Fibroblast	Collagen fibres	Mast cells
(b)	Mast cell	Macro-phage	Fibroblast	Collagen, fibres
(c)	Macro-phage	Collagen fibres	Fibroblast	Mast cell
(d)	Mast cell	Collagen fibres	Fibroblast	Macro-phage

18. Most of the cells in areolar tissue are

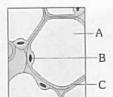

[NCERT;

[CBSE PMT 1992; MP PMT 1996; Kerala PMT 2010]

- (a) Fibroblasts
- (b) Macrophages
- (c) Mast cells
- (d) All the above
- 19. Histiocyte is a connective tissue cell, the function of which is
 - (a) Phagocytic
- (b) Secretion
- (c) Substanance
- (d) Fibre production
- 20. Ligament is mainly made up of
- [MP PMT 2007]

- (a) Reticulin
- (b) Elastin
- (c) Myosin
- (d) Collagen

- 21. A localised inflammatory response appears at the site of infection causes redness, swelling, pain and heat due to certain chemical, they are [KCET 2007; J & K CET 2012]
 - (a) Histamine and prostaglandins
 - (b) Cerumen and mucus
 - (c) Histamine and cerumen
 - (d) Prostaglandins and cerumen
- Thousand of year old Mummies are still in their condition as they were before due to non-destruction of [BHU 2005, 12]
 - (a) Yellow elastin fibres
- (b) White elastin fibres
- (c) Collagen fibres
- (d) Veins
- White adipose tissue contains
- (b) Bilocular fat cells
- (a) Multilocular fat cells
- (1) Al l f-1-II
- (c) Unilocular fat cells
- (d) Alocular fat cells
- 24. The given figure is of adipose tissue, identify marked alphabets

[NCERT]

IMP PMT 20031

2	A	В	С
(a)	Fat storage area	Nucleus	Cell membrane
(b)	Nucleus	Fat	Cell membrane
(c)	Cytoplasm	Fat	Cell membrane
(d)	Vacuole	Fat	Cell membrane

- 25. Debove's membrane is a layer of
- [BHU 2004]
- (a) Muscular tissue
- (b) Epithelial tissue
- (c) Connective tissue
- (d) All of these
- Which among the following is not characteristic of yellow fibres of connective tissue [Kerala PMT 2004]
 - (a) Contain elastin
 - (b) Fewer in number
 - (c) Straight and branched
 - (d) Provide toughness and strength
 - (e) Occur singly
- 27. Which one of the following is not a fibrillar protein

[Kerala CET 2003]

- (a) Elastin
- (b) Collagen
- (c) Myosin
- (d) Albumin
- 8. Vitreous humor is
- [BVP 2003]
- (a) Mucoid connective tissue (b) Solid crystalline
- (c) Watery fluid
- (d) All of these
- 29. Which of these if not found in connective tissue
 - [MP PMT 2010]
 - (a) Hyaluronic acid
- (b) Basement membrane
- (c) Collagen fibres
- (d) Fluid
- The ground substance of connective tissue is basically composed of [MP PMT 1997]
 - (a) Mucopolysaccharides
- (b) Lipids
- (c) Monosaccharides
- (d) Phospholipids

[CPMT 2001; BHU 2006; MP PMT 2012]

(b) Elastic cartilage

(d) Fibro cartilage

(a) Hyaline cartilage

(c) Calcified cartilage

31. Adipocytes are mainly found in [NCERT; MP PMT 1997] Select the option having all three correct characteristics (a) Bones (b) Cartilages [AIIMS 2012] Structure Percentage (c) Connective tissue (d) Nerves Function 32. Arbor vitae is composed of [AIIMS 1998] (a) Grey matter (b) Neurogleal cells 0.3 - 0.5(a) Phagocytic (c) White matter (d) All of these 33. Ligament is [CBSE PMT 1999; BHU 2000] Secrete histamine (a) Modifed white fibrous tissue 0.5 - 1(b) and serotonin (b) Modifed yellow elastic fibrous tissue (c) Inelastic white fibrous tissue (d) None of these Defence against 30 - 40(c) 34. Choose the correctly matched pair parasites [CPMT 1999; JIPMER 2001; CBSE PMT 2014] (a) Areolar tissue - Loose connective tissue (d) 30 - 40Allergic reactions (b) Cartilage - Loose connective tissue (c) Tendon - Specialized connective tissue (d) Adipose tissue - Dense connective tissue 45. Identify the following figure - A and B respectively [NCERT] Matrix Collagen 35. Which of the following is not a connective tissue [CPMT 2010] (a) Blood (b) Lymph (c) Nerve (d) Bone Which of the following cells is phagocytic in nature 36. [AFMC 2000; Odisha JEE 2011] (a) Mast cell (b) Podocytes Collagen Matrix (c) Macrophages (d) Fibroblast cells Fibre Fig. A Fig. B 37. Connective tissue is [Odisha JEE 2002] (a) Connective tissue proper, specialized connective tissue (a) Ectodermal in origin with intercellular spaces (b) Adipose tissue, specialized connective tissue (b) Mesodermal in origin without intercellular spaces Dense irregular connective tissue, dense regular (c) Ectodermal in origin without intercellular spaces connective tissue (d) Mesodermal in origin with intercellular spaces (d) Dense regular connective tissue, dense irregular 38. Mast cells are found in **INCERT: MP PMT 19971** connective tissue (a) Connective tissue (b) Muscular tissue Skeletal tissue (c) Nervous tissue (d) Blood Collagen is 39. [CBSE PMT 2002] Haversian system is a diagnostic feature of (a) Lipid [KCET 1994; MP PMT 2001; DPMT 2003] (b) Carbohydrate (a) Avian hones (b) All animals (c) Globular protein (d) Fibrous protein (c) Mammalian bones only (d) Reptilian bones 40. Which one of the following contains the largest quantity of 2. Which of the following tissue is more elastic extracellular material [NCERT: CBSE PMT 2003] (b) Cartilage (a) Myelinated nerve fibres (b) Striated muscle (c) Both are equally elastic (d) Both are not elastic (c) Areolar tissue (d) Stratified epithelium 3. Haversian system are found in the [BVP 2002] 41. Fibroblasts, macrophages and mast cells are seen in (a) Pigeon (b) Panther [Kerala PMT 2011] (c) Pipe fish (d) Python (a) Epithelial tissue (b) Connective tissue 4. Which of the following tissue is called as "homeostatic (c) Skeletal muscle tissue (d) Smooth muscle tissue reservoir" (e) Neural tissue (a) Cartilage (b) Bone Which of the following tissues is most abundant and forms 42. (c) Calcified cartilage (d) All the above most of the body parts [NCERT; Odisha JEE 2011] During an injury, nasal septum gets damaged and for its 5. (a) Nervous tissue (b) Muscle tissue recovery which cartilage is prefused [CBSE PMT 2001] (c) Connective tissue (d) Epithelial tissue Or 43. The falciform ligament in man connects Which of the following is a transparent tissue

[NCERT; AMU (Med.) 2012]

(b) Lungs with diaphragm

(a) Liver with diaphragm

(c) Stomach with diaphragm (d) Liver with stomach

BOOK DE	Role of bone-marrow in mammals is [MP PMT 1995]	18.	Red marrows of the bone produce [AIIMS 1993]
	(a) To assist kidneys		(a) Lymphocytes (b) Eosinophils
	(b) To act as haemopoietic tissue		(c) Plasma (d) RBC
	(c) To assist liver	19.	The connective tissue of the vertebrate body is built up from
	(d) To control blood pressure		fibres of the protein collagen, embedded in a polysaccharide
	Pubis in the frog's pelvic girdle is actually a [BVP 2003]		matrix to form [CBSE PMT 1993]
	(a) Calcified cartilage (b) Cartilaginous bone		(a) Cartilage (b) Blood vessel
	(c) Membrane bone (d) None of these		(c) Heart (d) Lung
	Which among the following is the strongest cartilage [CPMT 2000, 03; BHU 2003]	20.	In the matrix lies the bone cells, called [CBSE PMT 1993] Or
	(a) Hyaline cartilage (b) Elastic cartilage		Cells that maintain marrow cells are called [AFMC 2009]
	(c) White fibro cartilage (d) Violet fibro cartilage		(a) Chondroclasts (b) Osteoclasts
	Protein present in cartilage is [CBSE PMT 1997]		(c) Osteoblasts (d) Osteocytes
	Or	21.	A femur is kept in dilute HCI for three days, it becomes
	The matrix of hyaline cartilage contains [CPMT 1998]		[CBSE PMT 1993]
	Or Or		(a) Brittle (b) Soft and elastic
	The skeletal tissue consists of organic matrix called as		(c) Remains as it is (d) Harder
	[CBSE PMT 1993]	22.	A tissue similar to ligament but stretchable is called
	(a) Chondrin (b) Oesein		(a) Tendon (b) Raphe
2002	(c) Cartilagin (d) Ossein		(c) Both (a) and (b) (d) None of these
0.	The supportive skeletal structures in the human external ears	23.	Bone-forming cells are known as
	and in the nose tip are examples of [CBSE PMT (Mains) 2012]	20.	[NCERT; KCET 1998; PET (Pharmacy) 2013]
			(a) Chondroclasts (b) Osteoblasts
	(a) Ligament (b) Areolar tissue (c) Bone (d) Cartilage		(c) Chondroblasts (d) Osteoclasts
		24.	
11.	Covering around or to	24.	is [NCERT; AFMC 2012]
			(a) Ossein (b) Collagen
			(c) Chondroitin (d) Hyaline
12.	Haversian canals of long bones have	10000	
-	(a) One vein and one artery (b) One nerve and one lymphatic	li sono	Vascular tissue
	(c) Some bone cells, fat and areolar tissue	1.	Which is not the cellular element of blood[Odisha JEE 2008
	(d) All the above		(a) T-cell (b) B-cell
13.	Cartilage is formed by		(c) Plasma (d) Monocyte
13.	[NCERT; MP PMT 1993, 94; Manipal 1995]	2.	Average life span of human RBC is [NCERT
	(a) Osteoblast (b) Fibroblast		MP PMT 2001, 10; CPMT 2003; AFMC 2005
	(c) Chondrocyte (d) Submucosa		Odisha JEE 2005; BHU 2008
14.	In mammals Haversian canals are connected with each		(a) 100 days (b) 90 days
-E+	other by transverse canals, which are called		(c) 120 days (d) None
	IMP PMT 2001, 03: KCET 2004: AFMC 20081	3.	그는 그들은 선생님은 그렇게 되는 것이 되는 것이 되었다면 할 때 그 아이들은 아이들은 아이들은 아이들은 아이들은 아이들은 아이들은 아이들은
	[MP PMT 2001, 03; KCET 2004; AFMC 2008] (a) Semicircular canals (b) Volkman's canals	3.	When the count of WBC falls below the optimum number in blood, it is called [Odisha JEE 2005]
	(a) Semicircular canals (b) Volkman's canals	3.	blood, it is called (a) Leukopenia (b) Leukemia

51. Study the diagram given below and identify the cells labelled as A, B, C and D, and choose the correct option

[KCET 2012]

- (a) A = Eosinophil B = Erythrocyte, C = Neutrophil and
 - D = Basophil
- (b) A = Eosinophil, B = Lymphocyte, C = Neutrophil and
 - D = Monocyte
- (c) A = Erythrocyte, B = Basophil, C = Neutrophil and
 - D = Lymphocyte
- (d) A = Eosinophil, B = Monocyte, C = Neutrophil and
 - D = Lymphocyte
- 52. Which of the following is not phagocytic in nature [DPMT 2007; WB JEE 2011]
 - (a) Monocyte
- (b) Lymphocyte
- (c) Mast cell
- (d) Neutrophil
- 53. Which of the following work as phagocytes [AFMC 2003]
 - (a) WBCs
- (b) RBCs
- (c) Enzymes
- (d) Hormones
- 54. Serum is

- [Odisha JEE 2004]
- (a) Blood without fibrinogen
 - (b) Lymph without corpuscles
 - (c) Blood without corpuscles and fibrinogen
 - (d) Lymph
- 55. Which is correct

[Odisha JEE 2004]

- (a) Blood has WBC and lymph has RBC
- (b) Blood has WBC, RBC and lymph nothing
- (c) Blood has RBC, WBC and lymph has WBC
- (d) Lymph has WBC, RBC and blood has RBC
- **56.** Which of the following does not play a role in blood coagulation [CPMT 2004]
 - (a) Vitamin K
- (b) Vitamin D
- (c) Calcium ions
- (d) Fibrinogen
- 57. Which is not the function of lymph
- [MHCET 2015]
- (a) Transport R.B.C.s
 - (b) Drain excess tissue fluid
 - (c) Transport lymphocyte and antibodies
 - (d) Transport absorbed fat
- 58. Hematology is the study of

[BVP 2004]

- (a) Bone
- (b) Blood
- (c) Cartilage
- (d) Nerves
- 59. Antiserum contains
- [MH CET 2002; MP PMT 2012] (b) Antibodies
- (a) Antigens
- (b) Ailibodie
- (c) Leucocytes
- (d) Heptaus
- **60.** G-6-P dehydrogenase deficiency is associated with haemolysis of [CBSE PMT 2005]
 - (a) Lymphocytes
- (b) RBCs
- (c) Platelets
- (d) Leucocytes
- 61. Which of the following substances, if introduced into the blood stream, cause coagulation of blood at the site of its introduction [CBSE PMT 2005]
 - (a) Fibrinogen
- (b) Prothrombin
- (c) Heparin
- (d) Thromboplastin

62. Which are the phagocytic cells from given diagram

[MHCET 2015]

- (a) I and V
- (b) I and III
- (c) I and IV
- (d) I and II
- 63. The process of formation of RBCs is called
 - (b) Erythropoiesis
 - (a) Poikegenesis(c) Leucogenesis
- (d) None of these
- 64. Which of the following is not the main function of lymph glands [CBSE PMT 1998; AFMC 1999]
 - (a) Forming WBC
- (b) Forming antibodies
- (c) Forming RBC
- (d) Destroying bacteria
- 65. The process of formation of blood corpuscles is called

[AFMC 2005]

[AFMC 2009]

- (a) Haemopoiesis
- (b) Heamolysis
- (c) Heamozoin Mark the odd one
- (d) None of these
 [AFMC 2005]
- (a) Monocytes
- (b) Lymphocyte
- (c) Neutrophils

66.

- (d) Erythrocytes
- 67. A drop of each of the following, is placed separately on four slides. Which of them will not coagulate [CBSE PMT 2007]
 - (a) Blood plasma
 - (b) Blood serum
 - (c) Sample from the thoracic duct of lymphatic system
 - (d) Whole blood from pulmonary vein
- **68.** If haemoglobin (Hb) of a normal individual and a sickle-cell patient are run in electrophoretic field, they will show
 - [AMU (Med.) 2012]
 - (a) Same mobilities
 - (b) Different mobilities
 - (c) Hb of patient will not move at all
 - (d) Hbs are immobile
- 69. Which of the following is a type of white blood cell

[Odisha JEE 2012]

- (a) Reticulocyte
- (b) Lymphocyte
- (c) Erythrocyte
- (d) Osteocyte
- 70. Which of the following is absent in blood serum

[Odisha JEE 2012]

- (a) Antigens
- (b) Fibrinogen
- (c) Hormones
- (d) Antibodies

Irregular nuclei is present in

[MP PMT 2007]

Which white blood cell releases chemical to inhibit blood clotting [WB JEE 2016]

- (a) Neutrophils
- (b) Basophils
- (c) Eosinophils (d) Monocytes
- Which option is correct for the formation of 'Intrinsic factor X activator complex for blood coagulation [GUJCET 2014]
 - (a) Inactivated Christmas factor + AHG + phospholipids + Ca²⁺
 - (b) Activated Christmas factor + AHG + phospholipids + Ca²⁺
 - (c) Convertin + AHG + Ca2+ + FSF
 - (d) Phospholipid + protein complex + Proconvertin

- 73. Match the following
 - A. Neutrophil
 - B. Eosinophil
 - C. Basophil
 - Lymphocyte
 - E. Monocyte
- Single large nucleus
- 2 2 to 3 lobed nucleus
- 3. Kidney shaped nucleus
- 2 to 7 lobed nucleus
- 5. Bilobed nucleus

[Kerala PMT 2006]

- (a) (A) (4), (B) (1), (C) (3), (D) (5), (E) (2)
- (b) (A) (2), (B) (5), (C) (1), (D) (4), (E) (3)
- (c) (A) (4), (B) (5), (C) (2), (D) (1), (E) (3)
- (d) (A) (2), (B) (4), (C) (5), (D) (3), (E) (1)
- (e) (A) (1), (B) (4), (C) (3), (D) (2), (E) (5)
- 74. Innate immunity is provided by

[Bihar CECE 2006; J & K CET 2008]

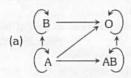

- (a) Neutrophils
- (b) T- cells
- (c) B- cells
- (d) Antibody
- 75. Amount of oxygen supplied by 100ml arterial blood while [WB JEE 2012] passing through the tissues is
 - (a) 0.4-0.6 ml
- (b) 4-6 ml
- (c) 14-15 ml
- (d) 19-20 ml
- People who have migrated from the planes to an area 76. adjoining Rohtang Pass about six months back

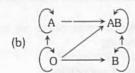

[NCERT; CBSE PMT (Pre.) 2012]

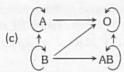

- (a) Have more RBCs and their haemoglobin has a lower binding affinity to O2
- (b) Are not physically fit to play games like football
- (c) Suffer from altitude sickness with symptoms like nausea fatigue etc
- (d) Have the usual RBC count but their haemoglobin has very high binding affinity to O2
- 77. Compared to those of humans, the erythrocytes in frog are

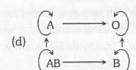

[NCERT; CBSE PMT (Pre.) 2012]

- (a) Without nucleus but with haemoglobin
- (b) Nucleated and with haemoglobin
- (c) Very much smaller and fewer
- (d) Nucleated and without haemoglobin
- See the following representations and identify the correct 78. blood groups and donor compatibility [NCERT]

- 79. Heparin is secreted by
 - (a) Blood cells
 - Kidney
- [MH CET 2001; WB JEE 2010]
- (b) Liver cells
- (d) Nerve cell

- 80. If pH of blood is artificially changed to 8, what is most likely [MP PMT 1992] to happen
 - (a) The tissues will not get oxygen as oxyhaemoglobin will not dissociate into oxygen and haemoglobin
 - (b) The carbon dioxide will not be released from carbonic acid and carbonates
 - (c) The carbonic anhydrase will be completely inhibited
 - (d) It will generate carbon monoxide and the animal will die of carbon monoxide poisoning
- 81. Erythropoesis may be stimulated by the deficiency of

[AIIMS 1992]

- (a) Iron
- (b) Oxygen
- (c) Protein
- (d) None of the above
- The figure shows a human blood cell. Identify it and give its 82. characteristics

[NEET (Kamataka) 2013]

	Blood cell	Characteristics
(a)	Basophil	Secrete serotonin, inflammatory response
(b)	B-lymphocyte	Form about 20% of blood cells involved in immune response
(c)	Neutrophil	Most abundant blood cell, phagocytic
(d)	Monocyte	Life span 3 days, produce antibodies

- 83. Blood cells that increase in number during allergic conditions like asthma are [AIIMS 2010]
 - (a) Neutrophils
- (b) Basophils
- (c) Eosinophils
- (d) Lymphocytes
- 84. The ratio of RBC to WBC in man is
 - (a) 6:1
- (b) 60:1
- (c) 600:1
- (d) 6000:1
- 85. Which of the following cells are round and biconcave in [Kerala PMT 2011]
 - (a) White blood cells
- (b) Red blood cells
- (c) Columnar epithelial cells (d) Nerve cells
- (e) Mesophyll cells
- 86. Which one is correct [KCET 2007; AIPMT (Cancelled) 2015]
 - (a) Blood = plasma + RBC + WBC + blood platelets
 - (b) Plasma = blood lymphocytes
 - (c) Neuron = cyton + dendrite + axon + synapse
 - (d) Lymph = plasma + RBC + WBC
- The sample of a healthy human blood is 87.
 - (a) Alkaline
- (b) Acidic
- (c) Neutral
- (d) None of these
- The iron free compound of haemoglobin is 88.
 - (a) Globin
- (b) Haematin
- Bilirubin (c)
- (d) Haemotoxin

		Animal Hissaes TT7	X DEPOT 1950

	(b) Produce antigens to combat antibodies	(b) 80-100 mg/100ml blood	
	(c) Carry oxygen around the body	(c) 30-70 mg/100ml blood	
	(d) Transport antigens to B memory cells in the lymph nodes	(d) 220-250 mg/100ml blood	

(A) They do not need to reproduce

(D) All their internal space is available for oxygen transport

(b) Only (A)

(d) (B) and (C)

(B) They are somatic cells (C) They do not metabolize

Options

(a) Only (D)

(c) (A), (C) and (D)

113. Which of the followings are required for blood clotting

[AFMC 2008, 10; MP PMT 2010]

	[AFMC 2008, 10; MP PM1 2010]	1.	Which of the following ion is necessary for the contraction of
	(a) K^+ , thromboplastin (b) Ca^{++} , thromboplastin		a muscles and nerve impulse transmission
	(c) Na^+, Ca^{++} (d) K^+ , prothrombin		[CPMT 1995; RPMT 1995; BHU 2005]
114.	Which one of the following is a matching pair of a certain		(a) Na ⁺ (b) K ⁺
	body feature and its value / count in a normal human adult		(c) Ca^{++} and Mg^{++} ions (d) None of these
	[AIIMS 2007, 08]	2.	Which one of the following pairs of chemical substances, is
	(a) Urea – 5–10 mg/100mL of blood	2.	correctly categorised [NCERT; CBSE PMT (Mains) 2012]
	(b) Blood sugar (fasting) -70-100 mg/100mL.		(a) Calcitonin and thymosin -Thyroid hormones
	(c) Total blood volume –5–6		(b) Pepsin and prolactin-Two digestive enzymes secreted in
	(d) ESR in Wintrobe method – 9–15 mm in males and 20–34 mm in females		stomach
115.	About 97% of O_2 is transported by RBC. The remaining 3% is		(c) Troponin and myosin-Complex proteins in striated
	[NCERT; Kerala PMT 2008]		muscles
	(a) Dissolved in plasma and transported		(d) Secretin and rhodopsin –Polypeptide hormones
	(b) Remains in lungs	3.	Shivering with cold in winter is caused by [MP PMT 2001]
	(c) Attached to cell membranes		(a) Voluntary action of striated muscles
	(d) Inside the mitochondria		(b) Voluntary action of unstriated muscles
116	(e) In peroxisomes Multi-lobed nucleus and granular cytoplasm are		(c) Involuntary action of striated muscles
110.	characteristics of which of the following types of WBCs		(d) Involuntary action of unstriated muscles
	[Odisha JEE 2010]	4.	Unstriped muscles are found in
	(a) Neutrophils (b) Monocytes		(a) Neck (b) Urinary bladder
	(c) Lymphocytes (d) Eosinophils		(c) Arms (d) Fingers
117.	In normal healthy individuals the percentage of adult and	5.	Cardiac muscles are having characters of
	fetal haemoglobin, HbA: HbA2: HbF is [AMU (Med.) 2009]	٥.	(a) Striped muscle (b) Unstriped muscle
	(a) 96:2:2 (b) 45:45:10 (c) 50:45:5 (d) 80:10:10		(c) Both (a) and (b) (d) None of these
110	(c) $50:45:5$ (d) $80:10:10$ The majority of CO_2 is transported into blood as	,	
110.	[CPMT 2009]	6.	Unstriped smooth muscles are found in
	(a) Bicarbonate (b) Sulphate		(a) Thigh (b) Eye muscles
	(c) Oxalate (d) Citrate	_	(c) Iris (d) Tongue
119.	Which of the following prevents the conversion of	7.	Sarcolemma is the covering of [MP PMT 2003]
	prothrombin to thrombin in an undamaged blood vessel		(a) Nerve fibres (b) Muscle fibres
	[KCET 2009]		(c) Bone marrow (d) Liver, kidney and stomach
	(a) Heparin (b) Calcium ions	8.	Sliding filament theory can be best explained as
100	(c) Thromboplastin (d) Fibrinogen		[AIPMT (Cancelled) 2015]
120.	What is true about RBCs in humans [CBSE PMT (Pre.) 2010] (a) They do not carry CO_2 at all		 (a) Actin and Myosin filaments shorten and slide pass each other
	(b) They carry about 20-25 percent of CO ₂		(b) Actin and Myosin filaments do not shorten but rather
	(c) They transport 99.5 percent of O ₂		slide pass each other
	(d) They transport about 80 percent oxygen only and the rest 20 percent of it is transported in dissolved state in blood plasma		(c) When myofilaments slide pass other, Myosin filaments shorten while actin filaments do not shorten
121.	Which one of the following plasma is involved in the		(d) When myofilaments slide pass each other actin
	coagulaton of blood [NCERT; CBSE PMT (Pre.) 2011]		filaments shorten while myosin filament do not shorten
	(a) Fibrinogen (b) An albumin	9.	Which of the following makes heart wall more thick
100	(c) Serum amylase (d) A globulin		[Odisha JEE 2011]
122.	Adult human RBCs are enucleate. Which of the following statement (s) is/are not most appropriate explanation for this		(a) Pericardium (b) Epicardium
	feature		(c) Myocardium (d) Endocardium
	(A) They do not need to reproduce	10.	Who propounded the "Sliding filament theory" for muscles

contraction

(b) H.E. Huxley

(c) A.F. Huxley

(d) H.E. Huxley and A.F. Huxley

(a) Cori

[NEET 2017]

Muscular tissue

[DPMT 1993]

In the thin filament of skeletal muscle fibre, a small globular 11. protein, that masks the active sites on the F-actin is [Kerala PMT 2007, 08] (a) G-actin (b) Actin (c) Tropomyosin (d) Troponin (e) Myosin 12. During muscular contraction, which of the following events occur (i) H-zone disappears (ii) A band widens (iii) I band reduces in width (iv) Width of A band is unaffected (v) M line and Z line come closer [EAMCET 2009; AIIMS 2012] (a) (i), (iii), (iv) and (v) (b) (i), (ii) and (v) (c) (ii), (iv) and (v) (d) (i), (ii) and (iii) 13. Epimysium, perimysium and endomysium are found in [MP PMT 2009] (a) Nerve (b) Blood vessel (c) Striated muscle (d) Uterus 14. Striped muscles have (a) One nucleus (b) Many nuclei (c) Two nuclei (d) No nuclei Oxygen dissociation curve for myoglobin is [AFMC 2008] (a) Sigmoidal (b) Hyperbolic (d) Parabolic (c) Linear The protein which maintains the muscular storage of oxygen 16. [CMC Vellore 1993; WB JEE 2011] (a) Myoglobin (b) Actomyosin (c) Myosin (d) Haemoglobin The interval between the beginning of electrical response 17. and peak of tension recorded is the [CMC Vellore 1993] (a) Latent period (b) Contraction time (c) Relaxation time (d) None of these Autorhythmicity is a special property of the muscles of the [KCET 1994] Or Striped and branched muscle are found in [CPMT 1994] (a) Liver (b) Intestine (c) Heart (d) Kidney 19. Which of the following is the example of structural protein [RPMT 2006] (a) Myosin (b) Collagen (c) Keratin (d) All of these

20.

Smooth muscle fibres are

and involuntary

and involuntary

voluntary

voluntary

(a) Cylindrical, unbranched, striated, multinucleate and

(b) Spindle-shaped, unbranched, non-striated, uninucleate

(c) Cylindrical, unbranched, non-striated, multinucleate

(d) Spindle-shaped, unbranched, striated, uninucleate and

21. The most abundant tissue in the body is

Or

Which tissue is most widely distributed in the body forming major part

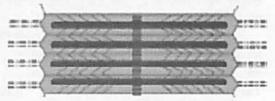

Or

In metazoa one of the following is responsible for locomotion and movement of organs [MP PMT 2001]

- (a) Nervous
- (b) Muscular
- (c) Vascular
- (d) Epithelial
- 22. All or none law is not applicable for

[WB JEE 2012]

- (a) Whole skeletal muscle
- (b) Single skeletal muscle fibre
- (c) Whole cardiac muscle
- (d) Single smooth muscle fibre
- 23. The muscles immune to fatigue are
 - (a) Striped
- (b) Unstriped
- (c) Cardiac
- (d) None of these
- State the condition of muscle contraction in following diagram [GUJCET 2015]

- (a) Resting potential
- (b) Contraction
- (c) Maximally contracted
- (d) None
- 25. Striated and voluntary muscle fibres are found in
 - [MP PMT 1999]

- (a) Lungs
- (b) Leg muscles
- (c) Gall bladder

[JIPMER 1993]

- (d) Blood vessels
- 26. Ciliary muscles are which

Or

Ciliay muscles are contractile structures which

- (a) Move cilia of some protozoans
- (b) Keep valves of heart intact
- (c) Change focal length of human eye and are found at joint of sclera and iris
- (d) Cause erection of human hairs in cold and are situated in skin
- 27. 'Oxygen debt' is amount of oxygen required for
 - (a) Muscle contraction
- (b) Muscle relaxation
- (c) Muscle recovery
- (d) All the above
- 28. In the resting muscle fibre tropomyosin partially covers

[AMU (Med.) 2010]

- (a) Ca binding sites on troponin
- (b) Actin binding sites on myosin
- (c) Myosin binding sites on actin
- (d) Ca binding sites on actin

Real Property lies			
29.	$Na^+ - K^+$ pump is found in membranes of many cells, like	37.	Statements
	nerve cells. It works against electro chemical gradient and		A. A – bands of the muscle is dark and contain myosin
	involve an integral protein ATPase. For each molecule of ATP used [AFMC 2006]		 B. <i>I</i> – bands are the light bands and contain actin C. During muscle contraction the <i>A</i> – band contracts
	(a) 3 ions of Na^+ are pumped out and two K^+ are taken in		D. The part between the two Z – lines is called as
	(a) 3 ions of Na^+ are taken in and $2K^+$ are pumped out		sarcomere
	(c) 2 ions of Na^+ are thrown out and $3K^+$ are absorbed		E. The central part of thin filament, not overlapped by
			thick filament is called H-zone
	(d) 3 ions of K^+ are absorbed and $3Na^+$ are pumped out		Of the above statements [Kerala PMT 2007]
30.	The 'thick' filament in muscles is polymerised protein of		(a) A, B and C are correct while D and E are incorrect(b) A, C, E are correct while B, D are incorrect
	[Kerala PMT 2012]		(c) A and B are correct while C, D and E are incorrect
	(a) Meromyosins (b) Actins (c) Troponins (d) Tropomyosins		(d) A, B, C and E are correct while D is incorrect
			(e) A, B and D are correct while C and E are incorrect
91	(e) Keratin Actin filament is made up of [BHU 2003]	38.	The structural and functional unit of the striated muscle fibre
31.	(a) Actin, troponin and tropomyosin		is called [CBSE PMT 1998]
	(b) Actin, troponin		(a) Sarcolemma (b) Sarcomere
			(c) Sarcoplasm (d) Myofibril
	(c) Myosin, troponin (d) Actin, tropomyosin	39.	Hypertrophy of muscle is
32.	Krause membrane or Z – line is a myofibril which separates		(a) Muscles become thin and weak due to excessive work
32.	two adjacent		(b) Muscles become thick and strong due to excessive work
	[CBSE PMT 2001; MP PMT 2002; Kerala PMT 2009]		(c) Muscles become thin and weak due to no work
	(a) Sarcomeres (b) H – zones		(d) Muscles become thick and strong due to no work
	(c) I - bands (d) A - bands	40.	Action potential is generated by [MP PMT 2007]
33.	The muscles which can retract are [CPMT 1998]		(a) Na^{+} (b) K^{+}
	(a) Retractor (b) Protractor		(c) Ca ⁺ (d) Cl ⁻
	(c) Abductor (d) All of these	41.	The largest muscle in human body is [BVP 2000]
34.	Read the statements regarding muscle proteins		(a) Masseter (b) Sartorius
	(A) Actin is a thin filament and is made up of two F-actins		(c) Stapedius (d) Gluteus
	(B) The complex protein, tropomyosin is distributed at	42.	The type of muscles present in our [NCERT;
	regular intervals on the troponin		CBSE PMT (Mains) 2011]
	(C) Myosin is a thick filament which is also a polymerized		(a) Thigh are striated and voluntary
	protein		(b) Upper arm are smooth muscle fibres fusiform in shape
	(D) The globular head of meromyosin consists of light		(c) Heart are involuntary and unstriated smooth muscles(d) Intestine are striated and involuntary
	meromyosin (LMM)	43.	The ready source of energy in living cells is [CPMT 1995]
	Of the above statements [Kerala PMT 2010]	40.	(a) Glucose (b) ATP
	(a) (A), (B) and (C) are correct		(c) Glycogen (d) ADP
	(b) (A), (B) and (D) are correct	44.	In a muscle, the functional unit of contraction is the
	(c) (A) and (C) are correct	• • • •	[Kerala PMT 2012]
	(d) (B) and (D) are correct		(a) Portion of myofibril between two successive 'Z'lines
	(e) (B), (C) and (D) are correct		(b) I band (c) A band
35.	Actin and myosin proteins are related with [BVP 2001]		(d) H zone (e) I band with a Z line
	(a) Na^+ and K^+ pump	45.	Unstriated muscles are found in [RPMT 1995]
	(b) Muscle contraction		(a) Veins (b) Arteries
	(c) Nervous system		(c) Uterus (d) All the above
	(d) Excretion of water products	46.	Which set clearly identify striated muscles [CPMT 2005]
36.	Myoglobin is found in		(a) Cylindrical, syncytial and unbranched
	[MP PMT 1997; AFMC 2000, 12; Pb. PMT 2000]		(b) Spindle, unbranched and uninucleated
	(a) Muscles (b) Blood		(c) Cylindrical, striped and nucleated
	(c) Liver (d) Spleen		(d) Cylindrical, striped and branched

Muscular tissue is differentiated into

[MP PMT 1995]

- (a) Unstriped, striped
- (b) Striped, cardiac
- (c) Cardiac muscle, unstriped
- (d) Unstriped, striated and cardiac
- During muscular contraction

IMP PMT 19961

- (a) ATP is broken down
- (b) ATP is formed
- (c) GTP is broken down
- (d) None of these
- The important muscle proteins that help in movement are

[AMU (Med.) 2012]

[AFMC 1994]

- (a) Actin and myosin
- (b) Tropomyosin
- (c) Troponin
- (d) All of these
- Cardiac muscle fibres differ from skeletal muscles because 50. these are [AIIMS 2000; MP PMT 2006]
 - (a) Striated, involuntary
- (b) Non-striated-voluntary
- (c) Non-striated involuntary (d) Antagonistic

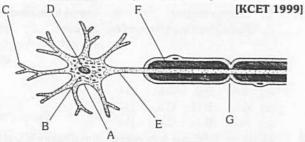

Nervous tissue

- Most of the neurons of our body are 1.

 - (a) Unipolar
- (b) Bipolar
- (c) Pseudounipolar
- (d) Multipolar
- 2. Synapses store
 - (a) Stimulating chemicals
- (b) Inhibitory chemicals
- (c) Conducting chemicals
- (d) All of these
- 3. Schwann cells and Node of Ranvier are found in

[DPMT 1993; BHU 2003; Kerala PMT 2009]

- (a) Nervous tissue
- (b) Osteoblast
- (c) Chondrioblast
- (d) Gland cells
- Which of the following is regarded as a unit of nervous tissue [CBSE PMT 1999]
 - (a) Axons
- (b) Dendrites
- (c) Neurons
- (d) Myelin sheath
- 5. Dark bands are
- [NCERT; CPMT 2009]
- (a) A-band (c) I-band
- (b) B-band (d) Z-line
- 6. In the diagram of multipolar myelinated neuron given below, different parts have been indicated by alphabetes; choose the answers in which these alphabetes have been correctly matched with the parts which they indicate

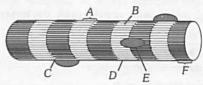

- (a) A=Cell body, B=Nissl bodies, C=Nucleus, D=Dendrites, E=Naked portion of axon, F=Myelin sheath, G=Node of
- (b) A=Cell body, B=Nissl bodies, C=Naked portion of axon, D=Dendrites, E=Nucleus, F=Myelin sheath, G=Node of
- (c) A=Cell body, B=Nissl bodies, C=Naked portion of axon, D=Nucleus, E=Dendrites, F=Myelin sheath, G=Node of
- (d) A=Cell body, B=Nissl bodies, C=Dendrites, D=Nucleus, E=Naked portion of axon, F=Myelin sheath, G=Node of Ranvier

- 7. Irritability and conductivity are maximum developed in
 - (a) Muscular tissue
- (b) Nervous tissue
- (c) Connective tissue
- (d) None of the above
- 8. Nerve cell originated from embryonic
 - (a) Ectoderm
- (b) Mesoderm
- (c) Both (a) and (b)
- (d) Endoderm
- Longest cell in human body may be

9.

- **IMP PMT 19981** (b) Leg muscle cell
- (a) Nerve cell
- (d) Heart muscle cell
- (c) Bone cell
- Nerve fibre is different from the muscle fibre due to the 10. presence of
 - (a) Myofibrils
- (b) Lines
- (c) Sarcolemma
- (d) Dendrites
- 11. The area where the medullary sheath is absent in the nerve fibre is called [CPMT 2009]
 - (a) Schwann cells
- (b) Schwann nodes
- (c) Nissl Granules
- (d) Node of Ranvier
- Nodes of Ranvier are found in [DPMT 2006; MP PMT 2011]
 - (a) Non-myelinated nerve fibres
 - (b) Myelinated nerve fibres
 - (c) Both (a) and (b)
 - (d) None of the above
- Neurons with long axons are called
 - (a) Golgi type I
- (b) Golgi type II
- (c) Golgi type III
- (d) Golgi type IV
- 14. The diagram given below represents the histology of a stripped muscle. Label the parts A, B, C, D E and F

- (a) A-Sarcoplasm, B-Nucleus, C-Sarcolemma, D-myofibril, E-Dark band, F-Light band
- (b) A-Sarcoplasm, B-Light band, C-Myofibril, D-Sarcolemma, E-Nucleus, F-Dark band
- (c) A-Light band B-Sarcoplasm, C-Myofibril, D-Sarcolemma, E-Nucleus, F-Dark band
- (d) A-Sarcolemma, B-Nucleus, C-Dark band, D-Light band, E-Sarcoplasm, F-Myofibril
- 15. Which of the damaged cells can not be repaired [AFMC 2006]
 - (a) Liver cells
- (b) Brain cells
- (c) Bone cells
- (d) Epidermal cells
- 16. Non-excitable cells, found among the neurons are called

[CPMT 2003]

Or

Which of the following is not the cell of aerolar tissue

[KCET 2001]

- (a) Dendrite
- (b) Axon
- (c) Schwann's cells
- (d) Nissl's body
- Myelin sheath is a layer covering
- [CMC Vellore 1993]
- (a) A nerve fibre in an insect
- (b) A chick embryo
- (c) A muscle fibre in a vertebrate
- (d) A nerve fibre in a vertebrate

18.	Myelin sheath is covering of		
10.	(a) Muscle cells (b) Axon of neurons		NCERT
	(c) Blood vessels (d) Osteocytes		ONCLINE
19.	The junction between Schwann cells is known as [MP PMT 1992]		Exemplar Questions
	(a) Plasmalemma (b) Node of Ranvier	1.	Which one of the following types of cell in involved in
	(c) Dendrons (d) Synapse		making of the inner walls of large blood vessels [NCERT]
20.	Myelin sheath is formed by [NCERT; CPMT 2010]		(a) Cuboidal epithelium (b) Columnar epithelium (c) Squamous epithelium (d) Stratified epithelium
	(a) Ranvier cells (b) Muscle cells	2.	To which one of the following categories does adipose tissue
	(c) Schwann cells (d) Axon	2.	belong [NCERT]
21.	The junction between the axon of one neuron and the		(a) Epithelial (b) Connective
	dendrite of the next is called [NCERT; CBSE PMT 1999;		(c) Muscular (d) Neural
	CPMT 2001; AFMC 2003; MP PMT 2003; Odisha JEE 2011]	3.	Which one of the following is not a connective tissue
	Or Other Section 1		(a) Bone (b) Cartilage
	Junction of two nerve fibres is called [MP PMT 2007]		(c) Blood (d) Muscles
	(a) A joint (b) A synapse	4.	Which one of the following statements is true for cockroach
	(c) Constant bridge (d) Junction point		[NCERT]
22.	Nissl's granules are found in cyton of nerve cells. These have		(a) The number of ovarioles in each ovary are ten
	affinity for basic dyes. The granules are made up of		(b) The larval stage is called caterpillar
	[MP PMT 1992, 97; CBSE PMT 2003; DPMT 2006]		(c) Anal styles are absent in females(d) They are ureotelic
	(a) Mitochondria (b) Cell metabolites	5.	Match the followings and choose the correct option
	(c) Fat granules (d) Ribosomes	J.	A. Adipose tissue i. Nose
23.	The afferent process of neuron is known as		B. Stratified epithelium ii. Blood
	(a) Axon (b) Dendrite		C. Hyaline cartilage iii. Skin
	(c) Cyton (d) Neurofibrillae		D. Fluid connective tissue iv. Fat storage
24.	Which of the following tissues in mammals show the least capacity for regeneration [CPMT 1995, 97; RPMT 2005, 06]		Options [NCERT]
	(a) Epithelial tissue of the skin		(a) A-i, B-ii, C-iii, D-iv
	(b) Endothelium of blood vessels		(b) A-iv, B-iii, C-i, D-ii (c) A-iii, B-i, C-iv, D-ii
	(c) Skeletal tissue of long bones		(d) A-ii, B-i, C-iv, D-iii
	(d) Nervous tissue of brain	6.	Match the followings and choose the correct answer
25.	Schwan cell is found around [BHU 2003]		A. Hermaphrodite i. Produces blood cells and
	(a) Axon (b) Cyton		haemoglobin
	(c) Dendrite (d) Dendron		B. Direct development ii. Testis and ovary in the same animal
26.	The most appropriate definition of Neuroglial cells are that		C. Chemoreceptor iii. Larval form absent
	they are [Kerala CET 2003]		D. Blood gland in earthworm iv. Sense of chemical
	(a) Nonsensory supporting cells		substances
	(b) Secretory cells		Options [NCERT]
	(c) Sensory cells		(a) A-ii, B-iii, C-iv, D-i
	(d) Sensory and supporting cells		(b) A-iii, B-ii, C-iv, D-i (c) A-i, B-iii, C-ii, D-i
27.	End plate junction is present between [CPMT 2010]		(c) A-i, B-iii, C-ii, D-i (d) A-ii, B-iv, C-iii, D-i
	(a) Neuron and striated muscle	7.	Match the following with reference to Cockroch and choose
	(b) Neuron and neuron		the correct option
	(c) Muscle and muscle		A. Phallomere i. Chain of developing ova
	(d) Both (b) and (c)		B. Gonopore ii. Bundles of sperm
28.	Nerve fibres conduct impulses in [RPMT 1999]		C. Spermatophore iii. Opening of the ejaculatory duct
	(a) One direction (b) Two direction		D. Ovarioles iv. The external genitalia
	(c) Multidirection (d) None of the above		Options [NCERT
29.	Which one of the following is not essentially a part of		(a) A-iii, B-iv, C-ii, D-i
	nervous system [CPMT 1998]		(b) A-iv, B-iii, C-ii, D-i
	(a) Cyton (b) Axon		(c) A-iv, B-ii, C-iii, D-i
	(c) Myelinated (d) Intermedin		(d) A-ii, B-iv, C-iii, D-i

(b) Ciliated

- Which one of the following mammalian cells is not capable 3. of metabolising glucose to carbon-dioxide aerobically

[CBSE PMT 2007]

- (a) White blood cells
- (b) Unstriated muscle cells
- (c) Liver cells
- (d) Red blood cells
- An epithelial tissue which has thin and flat cells arranged 4. edge to edge so as to appear like closely packed tiles, is found at the [CBSE PMT 1994; 2000]
 - (a) Inner lining of stomach
 - (b) Inner lining of cheeks
 - (c) Outer surface of ovary
 - (d) Inner lining of fallopian tube
- In heart cells, which one serves as a second messenger, 5. speeding up muscle cell contraction in response to adrenaline [Kerala PMT 2006]
 - (a) cAMP
- (b) cGMP
- (c) GTP
- (d) ATP
- (e) AMP

(b) Collagen

The major protein of the connective tissues is

(a) Keratin

(a) Dendrites

(c) Canaliculi

(b) Lamellae

(d) Haversian canals

[DPMT 1993; AIIMS 2001]

- (c) Melanin
- (d) Myosin
- The colour in the brown fat is due to
 - (a) Its larger capacity for generating heat

Processes from osteoblasts are called

- (b) Large number of mitochondria present
- (c) A high concentration of iron containing cytochrome pigments
- (d) Presence of chromatophores

Choose the correctly matched pair [CBSE PMT 2014] Polymorphonuclear leucocytes are [CBSE PMT 1993] 18. (a) Tubular parts of nephrons-Cuboidal epithelium (b) Lymphocytes (a) Monocytes (b) Inner surface of bronchioles-Squamous epithelium (c) Granulocytes (d) Agranulocytes (c) Inner lining of salivary ducts-Ciliated epithelium Hyaline cartilage does not have [DUMET 2010] 19. (d) Moist surface of buccal cavity-Glandular epithelium (a) Fibres (b) Lacunae The protein whose removal enables myosin to bind actin in (c) Cells (d) Blood capillaries [J & K CET 2012] smooth muscle is 20. In human embryo, main haemopoietic tissue is[CPMT 1993] (b) Caldesmon (a) Tropomyosin (a) Spleen (b) Liver (c) Myosin light chain kinase (d) Calmodulin Which pathway is correct for blood clotting [NCERT] (c) Bone marrow (d) Kidney 15. Thromboplastin or Thrombokinase Platelets release during blood clotting is [EAMCET 1998] 21. (a) Thrombin (b) Prothrombin V Ca⁺² → Thrombin Prothrombin -(c) Thrombokinase (d) Fibrinogen Fibrinogen + 22. Lymph contains dead and damaged (a) Only leucocytes formed elements (b) 99% lymphocytes, no RBCs and other leucocytes (b) Thromboplastin or Thrombokinase (c) 50% leucocytes and 50% erythrocytes (d) 99% erythrocytes and 1% small lymphocytes Thrombin > Prothrombin Bundles of striated muscle fibres called fasciculi are enclosed Ca+2 → Fibrinogen by a sheath called (b) Endomysium (a) Epimysium + dead and damaged formed elements (c) Perimysium (d) Peritoneum The value of resting membrane potential is Clot 24. Thromboplastin or Thrombokinase (c) [DPMT 1993; Kerala PMT 2006] -90mV (b) -100mV(a) Fibrinogen -+100mV +90mV (d) Prothrombin Thrombin 25. The triceps and biceps muscles are of (a) Antagonist type (b) Involuntary type Thrombin + dead and damaged (c) Smooth type (d) Sphincter type formed elements Poisons like cyanide inhibit Na^+ efflux and K^+ influx during 26. (d) Thromboplastin or Thrombokinase cellular transport. This inhibitory effect is reversed by an (from injured platelets / tissues) injection of ATP. This demonstrates that [CBSE PMT 1994] Prothrombin > Thrombin (a) ATP is the carrier protein in the transport system (b) Na⁺ - K⁺ exchange pump operates in the cell Fibrin Fibrinogen (c) ATP is hydrolysed by ATPase to release energy (d) Energy for Na+ - K+ exchange pump comes from ATP Clot Fibrin + dead and damaged 27. Actin binding sites are located on [Kerala PMT 2011] formed elements (a) Troponin Match the following 'A' (b) Tropomyosin A. Barr body Gives a grey colour to the (c) Meromyosin cell body (d) Both tropomyosine and meromyosin Conduction muscles of Purkinje cells (e) Both troponin and tropomyosin Lack of relaxation between successive stimuli in sustained 28. 3. Present in neurilemma C. Nissl bodies muscle contraction is known as [NEET (Phase-I) 2016] Certain neurons having Schwann cell (a) Spasm (b) Fatigue flask shaped cytons (d) Tonus (c)Tetanus Purkinje fibres Found in cytons of female The correct pairing is Which type of tissue correctly matches with its location (a) 5, 4, 1, 3, 2 (b) 3, 2, 5, 1, 4 [NEET (Phase-I) 2016] (d) 4, 3, 2, 5, 1 (c) 5, 2, 1, 3, 4 Tissue Location skeletal muscle, mostly due to Progressive degeneration of (a) Smooth muscle Wall of intestine [Kerala PMT 2010] genetic disorder occurs in (b) Areolar tissue Tendons (a) Myasthenia gravis (b) Muscular dystrophy (c) Transitional epithelium Tip nose (d) Osteoporosis (c) Tetany Lining of Stomach (d) Cuboidal epithelium (e) Arthritis

Assertion & Reason

Read the assertion and reason carefully to mark the correct option out of the options given below:

- If both the assertion and the reason are true and the reason is a correct explanation of the assertion
- (b) If both the assertion and reason are true but the reason is not a correct explanation of the assertion
- (c) If the assertion is true but the reason is false
- (d) If both the assertion and reason are false
- (e) If the assertion is false but reason is true
- Assertion : Total count of RBC comes out to be very low in polycythemia.
- Reason : Number of erythrocytes get reduced in the condition of polycythemia.
- 2. Assertion : Haemoglobin is said to be a conjugated protein.
 - Reason : It is composed of a protein called haem and a non protein iron porphyrin complex called globin.
- 3. Assertion : Histamine is involved in allergic and inflammatory reactions.
- Reason : Histamine is a vasodilator [AIIMS 2002]
 4. Assertion : Chilling of blood decreases coagulation
- time.

 Reason : Cold depresses the action of coagulation
- promoting enzymes.

 5. Assertion: Thrombin is necessary to initiate blood
- 5. Assertion : Thrombin is necessary to initiate blood coagulation.
 - Reason : Thrombin helps in the formation of thromboplastins.
- **6.** Assertion : Mast cells in the human body release excessive amounts of inflammatory chemicals which cause allergic reactions.
 - Reason : Allergens in the environment on reaching human body stimulate mast cells in certain individuals. [AIIMS 2003, 07]
- Assertion : The regulation of RBC production is accomplished by FSH.
 - Reason : Erythropoietin, hormone circulates to red bone marrow where it increases stem cell mitosis and speed up development of RBCs. [AIIMS 2002]
- 8. Assertion : Muscle cells are also called myofibrils.
- Reason : Muscle cells are very thin and elongated.

 9. Assertion : Thigh muscles can get tired but not the
- Assertion : Thigh muscles can get tired but not the muscles of ventricle of heart.
 - Reason : Muscles of thigh are voluntary whereas that of heart are involuntary muscles.
- **10.** Assertion : WBCs accumulate at site of wounds by diapedesis.
 - Reason : It is squeezing of leucocytes from endothelium. [AIIMS 2002]

- 11. Assertion : Non-striated muscles are said to be voluntary in nature.
 - Reason : Non-striated muscles can be moved according to will.
- 12. Assertion : Intercalated discs are important regions of cardiac muscle cells.
 - Reason : Intercalated discs function as boosters for muscle contraction waves.
- Assertion : Presence of connective tissue inside the brain is essential for conduction of nerve
 - Reason : Connective tissue hold together the nerve cells of brain.
- **14.** Assertion : Histamine is related with allergic and inflammatory reactions.
 - Reason : Histamine is a vasodilator.

impulse.

- **15.** Assertion : Non-myelinated nerve fibres do not possess nodes of Ranvier.
 - Reason : This is due to the absence of nissl's bodies in node of Ranvier.
- **16.** Assertion : Specialization of cells is advantageous for the organism.
 - Reason : It increase the operational efficiency of an organism. [AIIMS 2002]
- 17. Assertion : Cartilage (protein matrix) and bone (calcium matrix) are rigid connective tissue.
 - Reason : Blood is connective tissue in which plasma is the matrix. [AIIMS 2001, 13]
- **18.** Assertion : Materials can not be exchanged between epithelial cells.
 - Reason : Blood vessels are absent in epithelial tissue.
- 19. Assertion : The cells of columnar epithelium in absorptive surfaces often bears microvilli on their free ends.
 - Reason : Microvilli on their free ends.
- 20. Assertion : Fatigue is the inability of a muscle to relax.

 Reason : It is due to lactic acid accumulation by
- repeated contraction. [AIIMS 1998]
 21. Assertion : Fibroblasts help in protection.
- 21. Assertion : Fibroblasts help in protection.

 Reason : Fibroblasts synthesize two kinds of protein which are protective in nature.
- **22.** Assertion : Bones possess longitudinal canals called lacunae.
 - Reason : Lacunae carry blood vessels & nerves to the bones.
- 23. Assertion : Deposits of protein keratin are present in deeper layers of stratified keratinised squamous epithelium.
 - Reason : Keratin makes this epithelium impervious to water
- **24.** Assertion : Extracellular materials are important for cells.
 - Reason : Intercellular materials surround the cells & bind them together.

UNIVERSAL BOOK DEPOT 1960

456 Animal Tissues

25. Assertion : Simple epithelium covers surfaces exposed to mechanical or chemical abrasions.

Reason : Protection of underlying tissues is the major

function of simple epithelium.

26. Assertion: Tendon is present in all bone joints.

Reason : Tendon connects the bones at the joints &

hold them in position.

27. Assertion: Urinary bladder can considerably expand

to accommodate urine.

Reason : It is lined by stretchable squamous

epithelium.

28. Assertion : Granulocytes are white blood cells.

Reason : They contain lobed nuclei and tiny

granules. [AIIMS 2010]

29. Assertion : Columnar epithelium lining the intestinal mucosa appears to have a brush like

appearance.

Reason : A large number of microvilli are present on

brush bordered columnar epithelium.

30. Assertion: The regulation of RBC production is

accompanied by the kidneys.

Reason : Erythropoietin hormone circulates to the red bone marrow, where it increases stem

red bone marrow, where it increases stem cell mitosis and speeds up the development

of RBCs. [AIIMS 2009]

Epithelial tissue

- (b) Villi of intestine provide a velvety appearance and greatly increase the absorptive surface.
- 10. (a) Specialized cuboidal cells capable of producing gametes are found in gonads. Germinal epithelium produces gametes e.g., ova (female gamete) and sperm (male gamete).
- 11. (a) It is the mucous membrane of nasal passage.
- 12. (b) The ciliated epithelium in trachea, is infact pseudostratified ciliated epithelium having long ciliated columnar cells and short cuboidal cells.

- (c) Cells of squamous epithelium are flattened scale like and attached to each other like a mosaic.
- 15. (d) Stratified squamous epithelium occurs at surfaces subject to abrasion but protected from drying. Thus it forms the cornea of eyes, inner surfaces of eye lid, and the lining of buccal cavity, lower part of pharynx, oesophagus, vagina and vestibule of nasal cavities.
- 16. (b) Epithelial tissues have a widespread distribution throughout the body and serve several important functions such as protection, secretion, sensation and absorption.
- (a) Cells of simple epithelial tissue are arranged in a single layer.
- 18. (c) The outer most layer in epidermis of skin consist of keratinized stratified squamous epithelium cells. These cells slowly become dead, non nucleated and water proof.
- 21. (a) Cells of epithelium are set very close to each other, neighbouring cells are held together by cell junctions or desmosomes.
- 22. (a) In apocrine glands, secretory products accumulate at the apical margin. It pinches off from rest of the cell. The cell repairs the lost part, e.g., mammary gland.
- 23. (c) On the basis of mode of secretion pancreas, salivary gland and goblet cells are type of merocrine. In which secretion diffuses out through the cell surface.
- **26.** (a) The cell of Germinal epithelium is cuboidal, which are capable of producing gametes.
- 27. (a) Epithelial tissue has great regeneration power because when epithelia are injured they regenerate more rapidly than other tissues and thus facilitate rapid healing of wounds.
- (c) Ciliated columnar epithelium lines bronchioles and fallopian tubes.
- 29. (b) The skin epidermis of vertebrate animals is consist of keratinizing squamous epithelium in which cells of upper layer are dead with insoluble dead fibrous keratin protein.
- (d) Epithelia regenerate more rapidly than other tissues when injured.
- (a) Keratinised epithelium protects the underlying tissues from mechanical injury.
- 39. (b) Simple columnar epithelium lines the stomach, the small and large intestines, the digestive glands and the gall bladder.
- 41. (d) Following embryonic layers give rise to

Ectoderm - Epidermis

Mesoderm - Mesothelium

Endoderm – Epithelium of alimentary canal

 (a) Intestinal epithelium is glandular in nature and secretory in function.

Connective tissue

- 1. (b) Each liver lobe is formed of hexagonal lobules surrounded by a connective tissue sheath called Glisson's capsule.
- (d) Mast cells occur in connective tissue proper, these are modified basophils of blood. Mast cells secrete heparin, histamine and serotonin.
- (d) Areolar tissue fixes skin to underlying muscles or joins integument with muscles.
- (c) Ligaments are yellow elastic fibrous connective tissue while tendons are white collagen fibrous connective tissue.
- (a) Collagen fibres are white formed of a protein, occur in bundles, thick nonelastic with great tensile strength.
- 10. (d) Adipose tissue is a specialized loose connective tissue in which the fibroblast are modified for fat storage. Prominent adipose tissue sites are subcutaneous fat (panniculus adiposus), blubber of whales and hump of camel.
- 13. (b) Because adipose tissue takes part in the storage of fat which has the highest calorific value.
- 15. (d) Three types of fibres collagen, elastic and reticular are found in connective tissue. Each fibre consist of collagen, elastin and reticulin respectively.
- 17. (a) Correct labelling as follows

Macro-Phage Fibroblast Collagen fibres

Mast cell

- (d) Areolar tissue contains fibroblast, macrophages mast cells, plasma cells, lymphocytes and adipose cells etc.
- (a) Histiocyte is a phagocytic cell which is found in loose connective tissue.
- (c) Adipose tissue may be distinguished into two separate morphological type. White or unilocular fat and brown or multilocular fat.
- 27. (d) Albumin is a globular protein.
- (c) Adipocyte are fat cells, which are derived from fibroblast.
 These adipocyte are found in connective tissue.
- 33. (b) Ligament is a modified yellow elastic fibrous tissue which occur in the form of cords and binds a bone cartilage with another bone cartilage. It contains white fibres alongwith yellow fibres.
- 34. (a) Areolar and adipose tissue are loose connective tissue while tendon is dense connective tissue. Cartilage is specialized connective tissue.
- 36. (c) Macrophages engulf the invading microbes and destroy
- (d) It is albuminous protein which on boiling in water, changes into gelatin.
- 40. (c) As it has a large matrix with almost all types of cells and

Skeletal tissue

- (c) Mammalian bone is characterized by the presence of haversian system or osteon. Osteon is a basic structural unit of mammalian bone consisting of the haversian canal, lamellae and lacunae.
- (b) The presence of haversian system is a typical character of mammalian bone.
- 4. (b) Bone is also a metabolically dynamic tissue which functions as a homeostatic reservoir of ions of calcium, magnesium, phosphorous etc. About 97% of total calcium of body occurs in the endoskeleton.
- (a) Hyaline cartilage forms part of larynx, stemum, tracheal rings and nasal cartilages. Hyaline cartilage is the most abundant kind of cartilage with no fibres and transparent matrix. It is found upon articular surfaces at joints of long bones from articular cartilage, coastal cartilages at the ventral ends of the ribs. It helps to form the nose, larynx, trachea, bronchi and bronchial tubes leading to the lungs.

Fibrocartilage (fibrous cartilage) carries thick dense bundles of white collagen fibres in matrix. They are the strongest cartilage. They occur in joints between vertebrae and also pubic symphysis.

Tendon is a very dense, strong fibrous connective tissue made of collagen fibres. Tendon connects a skeletal muscle to a bone.

- (a) It is originally hyaline but later become calcified due to deposition of calcium salts in the matrix.
- (c) It has thick collagen fibres which provide strength, rigidity and firmness.
- (a) The chondrocytes secrete the flexible matrix called chondrin.
- (d) Cartilage is a type of connective tissue which is present in human external ears and in the nose tip.
- (b) Bone is surrounded by dense, white fibrous sheath called periosteum.
- 13. (c) The cells of mature cartilage called chondrocytes, occurs singly or in groups within spaces called lacunae. The chondrocytes secretes the flexible matrix called chondrin.
- (b) Haversian canals are interconnected by transverse canals known as volkmann's canals.
- 15. (a) The major component of vertebrate bone is calcium phosphate. Other components include calcium carbonate, magnesium phosphate and sodium chloride.
- **16.** (a) Tendon is white fibrous connective tissue which attaches muscle to bone.
- 17. (b) Intervertebral disc is a white fibrous cartilage.

- (d) In adult, red bone marrow (myleiod tissue) is responsible for producing red blood cells, granular leucocytes and platelets.
- 21. (b) If a bone is kept in dilute acid (HCI) for few days, it becomes soft and flexible. This is called decalcification of the bone.

Vascular tissue

- (c) The life span of biconcave RBCs in man is 120 days whereas in frog (biconvex RBCs or oval) is 100 days and in rabbit is 80 days.
- (a) Term leukopenia is applied when, decrease of the number of white blood cells below 5,000 per cubic milimeter.
- (d) Red bone marrow of long bone produces red blood corpuscles, white blood corpuscles and platelets.
- 8. (b) Camel has oval and nucleated RBCs.
- (d) Lymph can be defined as blood minus RBCs but more WBCs.
- **15.** (b) Because R.B.Cs. are isotonic to normal saline solution (0.8%NaCl).
- 17. (c) Amphibian RBCs are largest amongst the vertebrates. Those of Amphiuma and Proteus are largest amongst amphibians about 82μm.
 Mammals have smallest RBC's amongst the vertebrates. Those of Musk deer are smallest amongst mammals.
- 18. (a) Sodium oxalate, sodium citrate and EDTA (Ethylene diamine tetra acetic acid) are used as anticoagulants in blood banks as these bind Ca^{++} so these are called chelating agent.
- (d) Neutrophils, macrophages and lymphocytes protect the body against foreign microbes by phagocytosis and producing antibodies.
- 22. (d) Haemoglobin is an iron containing respiratory pigment occurring in vertebrate red blood cells and plasma of some invertebrate.
- 23. (c) Radioactive strontium –90 is very much similar to calcium in its chemical behaviour, so it gets deposited in the bone in place of calcium and then damage bone, bone marrow and other organs by continuously throwing out radiations and may also cause tumours and lead to bone cancer.
- 26. (b) Blood is a fluid connective tissue, which consist of blood corpuscles (RBCs, WBCs and Platelets) and plasma.
- 27. (b) Because of low oxygen demand.
- 34. (b) Reticulocyte stage is one phase of development of RBCs in which RBCs becomes immature.
- 35. (c) Phagocytosis, the process of engulfing of object (living or dead) by another organism was first discovered by Metchnikoff. He also gave the term phagocytosis.
- **36.** (c) Iron containing pigment haemoglobin is present in *RBC*.
- **38.** (a) Neutrophils are about 62% of the total number of white cells so most abundant sub type.
- 39. (c) Monocytes are the largest corpuscles and phagocytic.

- (a) Liver produces an anticoagulant, hetero-polysaccharide called heparin which prevent clotting inside the blood vessels.
- **41.** (a) Antibodies are produced by a sub population of white blood cells in the immune system called lymphocyte.
- 43. (a) Agranulocytes are leucocytes that lack granules in the cytoplasm. Since lymphocyte does not have granules in their cytoplasm, so it is called agranulocyte.
- 44. (a) The life span of the granulocytes once released from the bone marrow is normally 4-8 hours circulating in the blood and another 4 to 5 days in the tissue. The monocyte also have a short life span of 10 to 20 hours. The lymphocytes have life spans of few days or months or even years, but this depends on the body's need for these cells.
- 45. (b) Monocytes and lymphocytes are agranulocytes.
- 46. (a) Protein buffers in blood include haemoglobin and plasma proteins. Buffering is done by the imidazole group of the histidine residues. Haemoglobin is quantitatively about 6 times more important than the plasma proteins as it is present in about twice the concentration and contains about 3 times the number of histidine residues per molecule.
- 48. (c) The chief difference between RBCs of human and frog is that the human RBCs are without nucleus and therefore is not a complete cell. However the absence of nucleus in mammals increases respiratory efficiency of RBCs.
- 52. (b) Lymphocytes are non-phagocytic. They secrete antibodies to destroy microbes & their toxins, reject grafts & kill tumor cells.
- 54. (c) Serum is watery fluid left after the clotting of blood. Fibrinogen and corpuscles are absent in serum.
- **59.** (b) Antiserum contains antibodies for a specific antigen. This may be of human or animal origin.
- **61.** (d) Because the conversion of prothrombin to thrombin depends on the action of thromboplastin and calcium.
- 64. (c) We know that lymph glands are also called lymph node. They are composed of lymphatic tissue and give rise to special white blood cells and antibodies. They act as a defence barrier against the spread of infection by engulfing bacteria and other foreign materials from the lymph. They are not concerned with the formation of RBC.
- **67.** (b) Because there is no antibodies found in serum.
- **72.** (b) During blood coagulation, the intrinsic factor X activator complex is formed by Activated Christmas Factor (IX) + Antihaemophilic Globulin (AHG) + Phospholipid + Ca²⁺.
- 76. (a) People going to hilly areas will have polycythemia (more number of RBC in blood) after six months and their Hb has a lower binding affinity to O₂.
- 79. (b) Heparin is normally secreted by the mast cells of liver.
- 81. (b) The most important factor controlling the rate of red cell production in the oxygen content of the arterial blood, a decrease in oxygen content stimulates erythropoeisis.

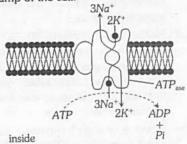

- 83. (c) Eosinophil is a type of white blood cell that has a granular cytoplasm. Its function involves the regulation of allergic responses and it also produces an enzyme capable of destroying parasites.
- 84. (c) The total number of WBC in 1ml is 8000 and number of RBC is 5 millions in 1ml
- 87. (a) pH of blood is 7.4 which is slightly alkaline.
- 90. (a) Thrombus is a clot formed inside the blood vessels. Thrombus is formed due to slowing of circulation and damage of the vascular endothelium.
- 91. (c) When air with low oxygen tension (anaemia) is breathed for some length of time, the cell count rises due to liberation of erythropoietin or haemopoietin or erythrocyte stimulating factor (ESF).
- 94. (b) pH of plasma is 7.4 which is slightly alkaline.
- Yellow substance oozing out of wound is in fact pus which consists of WBC, lymph and dead cells.
- 104. (c) RBC absorbs O2 to form oxyhaemoglobin.
- 106. (d) Since at high altitudes partial pressure of oxygen in air is less, so to facilitate the rapid gaseous exchange; heart rate, respiratory rate, vital capacity, total lung capacity, RBC count and haemoglobin percentage of persons living there increases.
- 107. (a) Blood corpuscle counting is done by this instrument.
- 108. (c) Potassium and sodium citrate remove the calcium ions from blood plasma.
- (a) Fibrinogen is a plasma protein involved in clotting of blood.
- 122. (a) Though, except metabolism rest three options are correct. Yet only statement D is related to their function

Muscular tissue

- (c) Ca⁺⁺ is a essential element for the contraction of muscles because release of Ca⁺⁺ ions from sarcoplasmic reticulum trigger the muscle contraction process.
- (c) Troponin is a protein which is found on Actin filament and myosin protein is found in myosin filament. Both Actin and Myosin are complex proteins in striated muscles.
- 3. (c) Involuntary action of striated muscles yield some heat to warm the body.
- (b) Unstriped muscles are the most widely distributed muscles in the body, e.g., Gastrointestinal tract, uterus, Urinary bladder, iris, ciliary body, blood vesseles etc.
- (c) Cardiac muscles have a mixture of properties of both striated and unstriated muscles. These muscles continue rhythmic contraction throughout life under the control of ANS.
- (b) The plasma membrane covering the muscle fibre is called sarcolemma.
- (b) Sliding filament theory tells that actin slides over myosin during contraction where the length of I-band and sarcomere reduces but no change in length of any filament.
- 9. (c) Myocardial layer contains cardiac muscles.

- (d) Sliding filament theory of muscle contraction was given by H.E. Huxley and A.F. Huxley.
- (b) A striped muscle fibre has many nuclei and it is a syncytium (coenocyte).
- 16. (a) The sarcoplasm also contains a protein pigment myoglobin, which can take up store or give up oxygen like haemoglobin.
- (c) Cardiac muscles can contract without the stimulation of nerves and they contract rhythmically.
- (b) Because there are about 639 muscles which constitutes the bulk of body, 40% of total weight and 50% of soft parts.
- 23. (c) Due to long refractory period.
- 25. (b) Striated muscles (voluntary muscles) are mostly attached to bones through tendons. The muscles are most abundant in limbs.
- 26. (c) Ciliary muscles by their contraction exerts tension over the zonule, the ligament which suspends the lens and stretch or relax the lens capsule. The lens has elasticity and hence change of tension on it changes the focal length of lens.
- 27. (c) During active work, the rate of oxygen supply by the lungs falls short of requirement of the muscles. Hence, lactic acid accumulates in the muscles and the breathing gradually becomes hard to enhance O₂ intake by the lungs. This is called oxygen debt.
- 29. (a) Energy from ATP cause conformational change in the solute carrier complex. From energy of one ATP, 3 Na⁺ are pumped outside and two K⁺ are taken in. This process of expelling out Na⁺ ions and drawing in K⁺ ions against the concentration gradient and electrochemical gradient is called sodium-potassium exchange pump of the cell.

This pump operates by involving the $Na^+ - K^+ - ATP$ are enzyme located in the cell membrane. Such electrogenic pump develops positive charge outside the membrane and negative charge to cell's interior. This difference in charge on either side of the membrane of a resting neuron is the resting membrane potential.

- 31. (a) One thin filament probably contains 300-400 actin molecules about 50 tropomyosin and 50 troponin. It is said that tropomyosin plays a vital role in sensitizing the contractile proteins (actin and myosin) to calcium ions.
- 35. (b) Actin and myosin are related with muscle contraction. In muscle contraction, overlapping of actin and myosin molecules interact to form actomyosin complex.

- (a) Muscles have their own oxygen-carrying iron-protein pigment myoglobin or muscle haemoglobin.
- **38.** (b) The distance between two *Z*-lines is called as sarcomere which is a functional unit of the muscle. Each sarcomere includes one complete A-band and 2 halves I-bands on the sides (I/2+A+I/2).
- 39. (b) Increase in the size of an organ because of enlarged cells is called hypertrophy.
- 41. (d) Gluteus maximus is the largest muscle. It is present in the buttock and extends and rotates the thigh laterally.
- 43. (b) The immediate energy source for muscle contraction is ATP which is present only in small quantities at any given time in the muscle.
- 48. (a) During muscle contraction, ATP undergoes hydrolysis in the presence of water and myosin ATP are to form ADP + Pi and liberation of energy.
- 50. (a) Cardiac muscles form the walls of heart. These are intermediate in structure being striated and involuntary. It is meant for automatic and rhythmic contraction. On the other hand skeletal muscles are striated and voluntary, they are most abundant and found attached to skeleton. They are supplied by somatic nerve and hence are under voluntary control.

Nervous tissue

- (d) Multipolar neurons have several dendrites and one axon. Most neurons in the brain and spinal cord of our body are of this type.
- 3. (a) Schwann cells are specialised glial cells that form the myelin sheath that coats axons. In peripheral nerve fibre the myelin sheath is interrupted at regular intervals; these interruptions constitute the node of Ranvier.
- (c) Neurons are structural and functional units of nerve tissue. Their number is quite high, more than 1×10¹² in brain alone.
- (b) Nervous tissue consists of cells having a well developed power of irritability and conductivity, forms nervous system.
- 8. (a) The whole nervous system originates from the ectoderm.
- (d) Nerve fibres are extended axons or dendrites. Dendrites carry nerve impulses toward the cell body and axon away from it.
- 13. (a) Neurons are of two types on the basis of axon length, Golgi type-I and Golgi type-II. In Golgi type-I, neuron possess very long axons.
- 15. (b) Two type of brain cells are found: The neuron and neuroglia. Neurons are functional typical nerve cells which generate and conduct impulses. Due to high degree of specialization the neuron lose their ability to divide. The neuroglia are with ability of division.
- (c) Non-excitable, supporting components of the nervous tissue include neuroglial cells and schwann's cells.
- 18. (b) Myelin sheath is a layer covering of vertebrates nerve fibre
- (b) Schwann's cell secrete a segment of myelinated fibre called internode.
- 22. (d) Nissl granules or Nissl bodies are basophilic structure of various shapes-angular, conical or rhomboidal. They are pieces of granular endoplasmic reticulum with or without free polyribosomes. They are found in cytons.

- 23. (b) Because dendrite receives the impulse for neuron.
- 28. (a) If a nerve impulse was initiated somewhere in the middle of a nerve fibre, it would proceed to both ends. However, in the synapse, the propagation is strictly one-way from the axon to the dendrite never the reverse.

Critical Thinking Questions

- (b) Inner lining of cheeks have compound stratified squamous epithelium.
- 6. (c) Epidermis has several distinct layers of epithelial cells. The innermost layer called stratum germinativum has columnar cells resting upon a common basement membrane.
- (c) Canaliculi are the protoplasmic processes between osteocytes.
- 11. (b) Connective tissues function in binding together and constitute the framework of many organs. Collagen is a protein of connective tissue that combine to form the tendons and ligaments.
